[1]A complete list of the officers and committees o the Society will be found in the Year Book for 1917 and in the March, 1917 issue of The Journal.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

EVERYONE is asking what the Society is doing to help the Government. First, a committee, consisting of Messrs. George J. Foran, Chairman; A. D. Blake, Henry C. Meyer, Jr., C. M. Allen and John H. Barr, has issued a personal classification sheet to every member of the society, and the replies are being collated. Already four hundred names of members of the society have been furnished the Government in answer to specific requests from the War Department. This is in addition to the work of the Employment Bureau, through which the Society gives special attention in the matter of placing men in positions in the industries.

Second, the society is an active member of the Engineering Committee of the Advisory Commission of the National Council of Defense, and several meetings have been held leading to definite and constructive assistance in the manufacture of munitions and in foreseeing the wants of the Government in the matter of power.

Third, as has already been stated, many of the members of the Society are serving on the Engineering Committee of the National Research Council, which is maintained by the funds of the Engineering Foundation, and in which this Society is a participant.

Fourth, as a result of the Spring meeting of the Society, a committee has been appointed by the Council, with the President as chairman, which will first investigate and then recommend to the Council how this Society can best assist in the establishment of a comprehensive system of the manufacture of munitions in the United States, including the establishment of a Central Bureau for master gages and district headquarters for copies of those gages, with provision for the comparison of working gages with those copies of the master gages, similar to what it is understood is in vogue in Canada.

The United States must in this present crisis be conducted as one business, with every man, woman and child working to a common end.

In another column are given the appointments on the Engineering Council, and it is possible now to accomplish many of the activities which the engineering profession, as a whole, may undertake. A meeting for the organization of the Council will be called in the near future.

The Society is also in conference with the Adjutant-General of the State of New York, through whose office has been established the Resource Mobilization Bureau of the State of New York, and is prepared to render similar services to the officers of other states in connection with taking industrial censuses.

The Secretary would be pleased to receive suggestions of ways in which the Society can render further service, and also offers of individual services in addition to what may be included in the personal classification sheets just issued to the membership.

CALVIN W. RICE,
Secretary.

COUNCIL NOTES

A MEETING of the Council was held on May 21, in Cincinnati, Ohio, in connection with the Spring Meeting. The following members were present: Ira N. Hollis, *President*, John H. Barr, C. H. Benjamin, W. F. M. Goss, James Hartness, Oberlin Smith, F. R. Low, chairman of the Publication Committee, and Calvin W. Rice, *Secretary*.

Engineering Resources. George J. Foran, chairman, C. M. Allen, John H. Barr, A. D. Blake and H. C. Meyer, Jr., were appointed a special committee on Engineering Resources to prepare a Personal Classification Sheet[1] for the purpose of putting on file immediately, classified data of the membership, to be of assistance in placement activities in the present national emergency.

Finance Committee. Upon recommendation of the Finance Committee, it was decided to subscribe to ten thousand dollars of U. S. Liberty Bonds, taking the necessary money from funds of the Society, even at some inconvenience.

Engineering Council. Five representatives of our Society were appointed on the Engineering Council, as follows: Charles Whiting Baker, John H. Barr, Arthur M. Greene, Jr., Ira N. Hollis and D. S. Jacobus.

Constitution and By-Laws. Amendments to the Constitution and By-Laws as presented by the Committee on Constitution and By-Laws were referred to the Business Session of the Spring Meeting. These amendments deal with standing committees, professional committees, discussion of political matters, and quorum at Council meetings. They will be again brought up at the Annual Meeting.

Joint Committee on Terminology. In response to an invitation from the National Electric Light Association, H. C. Anderson, N. A. Carle and F. R. Low were appointed to represent the Society on an advisory committee on Terminology.

Sections. The following executive committees for the Sections of Baltimore, Indianapolis, New York and Toronto were approved:

Baltimore: W. W. Varney, chairman; L. B. Robertson, vice-chairman; A. G. Christie, secretary; C. C. Thomas, treasurer, and Wm. Chatard, member executive committee.

Indianapolis: W. H. Insley, chairman; L. M. Wainwright, vice-chairman; B. G. Mering, treasurer; F. C. Wagner and L. W. Wallace.

New York: John J. Swan, E. J. Prindle, A. D. Blake, J. H. Norris and W. H. Greul.

Toronto: G. V. Ahara, R. W. Angus, C. R. Burt, L. H. Fletemeyer and C. B. Hamilton.

[1] This form has been sent out to the membership during the past month.

Student Branches. The establishment of a Student branch at Michigan Agricultural College, East Lansing, Mich., was approved.

Standardization Committee. Upon recommendation of the Standardization Committee there is to be appointed a committee on standardization of small hose couplings, other than fire hose couplings. A committee on standardization of roller chains is also to be appointed.

A.S.M.E. Boiler Code. Interpretations in cases Nos. 146 to 152 were approved and ordered published in THE JOURNAL. They are included in this issue.

CALVIN W. RICE, *Secretary.*

SPRING MEETING ENTERTAINMENT

THE entertainment arranged by the Cincinnati Local Committees for the Spring Meetings of our Society and of the National Machine Tool Builders' Association, demonstrated alike the inventive capacity and hospitality of Cincinnati engineers. Event succeeded event in almost startling array, and with a perfection of detail such as only a master hand can give.

THE SMOKER

Tuesday evening was "pleasure first" night, with which no one was supposed to allow any duties to interfere. It was the night of the smoker, and, so far as known, every engineer in attendance at the meeting responded to the call to be at the Business Men's Club "promptly at 8 o'clock" to participate. Shortly after arrival the company formed in a procession, headed by President Hollis and F. A. Geier, and was conducted to the large hall of the club by a fifer and drummers, veterans of the Civil War, who portrayed the "Spirit of '76," as well as the spirit of hospitality of 1917. When in the hall the visitors found themselves facing the street of a mining town of the far-western type, realistic in every detail. It proved to be Losantiville, the pioneer settlement from which grew the city of Cincinnati. Here were the early settlers true to life—historic characters, all of them, including the engineer who was to lay out and develop the city that was to be. There was an attack by Indians, and then a peace conference, at which the engineer saved the day by a portrayal of the possibilities of the future for the community. Peace declared, all were invited "inside" to celebrate.

The complete program of the evening comprised 18 numbers. A band played spirited music, and patriotism was cultivated by a quartet in khaki, which sang several national airs amid appropriate surroundings. There was a mock trial, with many unique features, including the musician, who demonstrated that he was an "engineer," and so eligible for jury duty, by playing most remarkably on the one string of a violin which he had constructed of a "cigar box and a broom handle." In this and in the laughable presentation of the Cincinnati plan of education which followed, the characteristics of several prominent members of the profession were portrayed in a way that delighted the audience. The mock trial was preceded by a rapid-sketch artist, who brought into the limelight several members of our Society and of the National Machine Tool Builders' Association.

At the close of the evening, promptly at 12 o'clock, Dr. Hollis was called to the stage and addressed by Chairman Geier, who expressed the pleasure that all Cincinnati members would feel in presenting him with a token of their esteem. Thereupon H. M. Norris, of the entertainment committee, headed a procession for the stage, and bore a large vase to the platform. But alas! as the top step was reached, Mr. Norris tripped and fell, the vase was shattered, and a look of consternation was on every face. Nothing abashed, Mr. Geier stepped forward and said that the committee would now make a presentation of a Cincinnati product, and thereupon gave Dr. Hollis a bit of beautiful Rookwood pottery, a framed plaque representing a woods scene in the vicinity.

A bounteous repast—no mere luncheon—was served during the evening; and at intervals the hall was made beautiful by remarkable kaleidoscopic lighting effects produced by throwing lights against slowly rotating colored balls with myriads of reflecting surfaces.

ENTERTAINMENT FOR THE LADIES

While the men were at the smoker the ladies were not forgotten, for they were asked to assemble in the small ballroom of the Hotel Sinton to witness a performance under the direction of Helen Schuster-Martin, Managing Director of The Little Playhouse Company, Cincinnati. Two plays were given, "The Maker of Dreams," by Oliphant Downs, and "How He Lied to Her Husband," by Bernard Shaw. These were followed by a dancing pantomime.

The ladies' committee, of which Mrs. R. K. LeBlond was chairman, issued a very attractive program for the occasion.

In many ways throughout the meeting the stay of the ladies in Cincinnati was made pleasant for them through their gracious reception by the Cincinnati ladies. For Monday visits were planned to the wonderful new city hospital and to the Woman's Club. On Tuesday was an excursion to Rookwood Pottery and the Art Museum, and in the afternoon an automobile ride to Fort Thomas and tea at Hotel Altamont. Tuesday was styled "Ladies' Day." It was, indeed, a day of pleasure for the visiting ladies.

On Wednesday and Thursday were other excursions, shopping trips, automobile rides, etc., in addition to the events in which both men and women participated.

BOAT TRIP AND AUTOMOBILE RIDES

On Wednesday all went on the *Island Queen* to Fernbank Dam and back, and enjoyed a delightful afternoon. The spacious dancing floor of the large boat was well patronized, and there was an amusing cakewalk competition by three "darky" couples engaged for the occasion, who did the stunt in true Southern fashion. Prizes were awarded according to the amount of applause.

On Thursday afternoon there was a procession of 160 automobiles bearing the party for an afternoon's outing, and, as some one remarked, "Not a 'flivver' among them." Two service automobiles accompanied the party. They were not needed, but their presence indicated the extreme care that was being given by the local committees for every detail. The ladies had had luncheon at the Zoological Garden, where they were met by the men, and from where all went to the Country Club for tea. A considerable number also were taken on rides on Friday afternoon.

VISITS TO SHOPS

For the engineers present, one of the great features was the opportunity of visiting the shops of the city, so many of which

have new and modern structures. The development of these shops in output and in progressive methods during the past few years has been very noteworthy.

As a courtesy on the part of the Lunkenheimer Company, a very handsome souvenir was distributed in the form of a paperweight bearing the American eagle mounted on a flag-decorated standard. Not only was this an attractive gift, but one that interested many because of the refinements of production required in its manufacture.

WEDNESDAY EVENING'S ENTERTAINMENT

The guests who went to the grand ballroom of the Hotel Sinton on Wednesday evening expecting to participate in the usual dance and reception were both surprised and pleasantly disappointed. The dance was held, it is true, but not until a most elaborate entertainment had been given on the ballroom stage. There was a series of finely executed moving pictures of the maneuvers of the Ohio cavalry troop on the Mexican border, besides pictures of Cincinnati and vicinity, and a film prepared specially for the occasion of the Cincinnati Committee preparing for the convention. The finance committee was shown collecting the funds, and woe-betided any wealthy manufacturer who entered the room, for his pockets were instantly rifled and his funds commandeered for the use of the committee. In disbursing the funds, the committee decided after their own manner how this should be done, incidentally pocketing occasional stray dollars.

There were music and professional dancing on the stage, and the entertainment concluded with an elaborate interpretive dance performance by the Goldenburg Players of Cincinnati. This was the portrayal of a fanciful tale in which children largely participated, and drew the enthusiastic applause of the audience. It was the most spectacular performance of the whole meeting, and greatly enjoyed and appreciated.

C. Wood Walter

J. B. Doan, President N. M. T. B. A.

A. H. Tuechter

One of the Pleasant Features of the Spring Meeting was the Association with the National Machine Tool Builders' Association. President Doan and Messrs. Geier, Walter and Tuechter Constituted the N. M. T. B. A. Executive Committee.

Business Meeting at Cincinnati

As usual, preceding the first session of the Spring Meeting was the regular business meeting. The chief item of business was the announcement of certain proposed changes in the Constitution which will later be submitted to the membership for letter-ballot and then will come up for discussion and action at the next Annual Meeting. These changes relate to age limit for junior members; reduction in the number of Standing Committees; change in the number of members constituting a quorum of the Council; provision for an increased number of so-called Annual Committees; etc.

President Ira N. Hollis announced that the Council had voted to invest $10,000 of the Society's funds in a subscription to the Liberty Loan, even at some slight inconvenience; and that whereas the Council alone had authority to do this, nevertheless it was desired to apprise the meeting of this action. In taking this action the Council felt that, as the agent of the entire Society, it was voicing the overwhelming opinion of the membership in its desire to subscribe to the success of what everyone had so much at heart.

It was further announced by President Hollis that a Committee on Engineering Resources had been appointed, which was about to issue a blank to the membership for the purpose of securing data upon the professional experience of each member and his ability to serve the Government, should the call come for engineers to enter Government service. He said that he believed the country would not make the mistake that England made at the outset of the war by sending her best industrial men to the trenches. While many engineers would go into the Army, and many of the graduates of his own institution, the Worcester Polytechnic Institute, had already gone as reserve officers, he thought every man in the Society ought to do contentedly and willingly the thing that he was best adapted to do.

MAJOR GENERAL GOETHALS ELECTED HONORARY MEMBER

To the list of illustrious men who have been honored by the Society there is added one more name—that of Major General George W. Goethals, who will go down in history as the builder of our "Big Ditch," the Panama Canal.

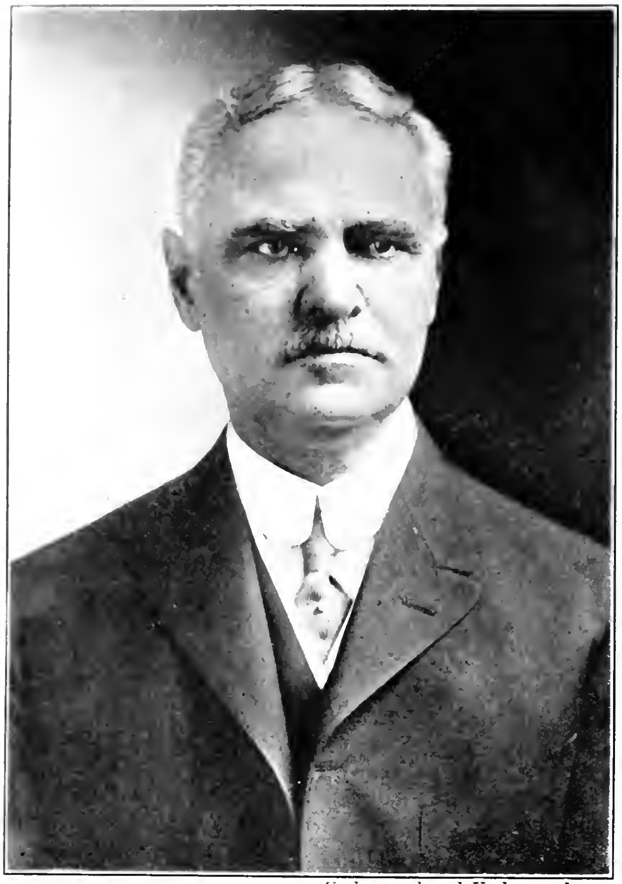
The preeminent gifts of "the Colonel," as thousands of Canal workers have known him affectionately during their work on the Isthmus, have been demonstrated in many ways but most conspicuously in two directions first, in his truly marvelous capacity for mastering and retaining details, and second, in his ability to win the confidence and inspire the loyalty and enthusiasm of those working under him. He is one of those rare persons whose full knowledge of details does not hamper his mental vision. He possesses the one all-necessary gift for successful leadership—sagacity.

Innumerable sketches of General Goethals' life have been written, but the facts and incidents of a great career are always of interest.

George W. Goethals was born in Brooklyn, N. Y., in 1858. His was not the carefree life of many a youngster, for at eleven years of age he began work as an errand boy in a broker's office, working after school hours and in the evenings. As proof of his efficiency, at fourteen he was cashier and bookkeeper of a firm. At this time he was studying in the College of the City of New York. His early ambition was to be a doctor, and with this end in view he matriculated at Columbia University; but poor health compelled him to give up this plan. He made a number of attempts to get an appointment to the United States Military Academy at West Point before he was successful. However, in 1876, at the age of 18, he received his appointment, and under the strict régime of that famous institution soon regained his full strength and health. He attained there the three principal honors within the reach of a cadet: he stood second in his class in scholarship, he was chosen as one of the four captains of the cadet corps, and he was elected senior president of his class. He was graduated in 1880, receiving an appointment as second lieutenant in the Corps of Engineers. In 1885 he returned to West Point and served as assistant professor of military engineering until 1888.

He gained his practical experience for the great task of Panama by hard work and tireless energy. Among his most important tasks were the construction of dams, canals and locks at Mussel Shoals in the Tennessee River, and the extensive fortification and harbor work at Newport, R. I. In 1903 he was called to Washington as a member of the General Staff, one of the first engineers to be so appointed.

It was in 1903 also that he was appointed chairman as well as chief engineer of a new commission—composed on its technical side of army and navy officers—for the completion of the Panama Canal.



Underwood and Underwood.

Major General George W. Goethals

His work on the Canal is distinguished by its signal efficiency. Everyone on the Isthmus worked hard, but none worked harder than did "the Colonel." He stopped work at night only to sleep, and sometimes, in his own phrase, he "took the Canal to bed with him."

If there was anything more wonderful on the Isthmus than the efficiency of the force that was building the Canal, it was its *esprit de corps*. Everybody from "the Colonel" down and back again believed in the Canal, loved the Canal and fought the great fight that made the Canal a reality. Toward his fellow-workers his motto was, "Be considerate, just and fair with them in all dealings, treating them as fellow-members of the great brotherhood of humanity."

"Tell the Colonel," was the characteristic refrain of a popular song on the Isthmus, and everyone proceeded with his grievance, problem or suggestion to follow that rule. In turn they received ungrudging justice, all-around helpfulness and cordial recognition. The building of the Panama Canal will always stand as a monument of fame to "the Colonel."

In 1913 the degree of LL.D was conferred on him by the University of Pennsylvania. In the spring of 1914 he was awarded medals by the National Geographic Society, the Civic Forum (New York), and the National Institute of Social Sciences. Late in 1913 and early in 1914 he was in demand for various administrative positions, declining the police commissionership of New York City, offered to him by Mayor Mitchel and the "city managership" of Dayton, Ohio. On February 3, 1914, he was appointed by President Wilson the first civil governor of the Panama Canal Zone. By act of Congress, March, 1915, he was made Major General. On June 11th of this year Rutgers College conferred on him the honorary degree of Doctor of Science.

Though appreciative of all his many honors, General Goethals is unusually averse to having any public recognition made of his work, and finds his greatest satisfaction in the completion of what he set out to do.

Just recently, in April of this year, General Goethals agreed to supervise the building of ships authorized by Con-

gress to be built under the United States Shipping Board Emergency Fleet Corporation. In view of the National call upon his services he has been released by Governor Edge of New Jersey from his contract to supervise the $15,000,000 expenditure for reconstructing the highways of that state.

General Goethals' success is due to a few broad, solid and simple principles, at the base of which lies the quality of loyalty. He believes profoundly in action and in taking responsibility. He believes that the sense of duty to one's self and to one's country should be the incentive to achievement—not the hope of reward either in profit or fame.

Formal presentation of the "diploma" of honorary membership will be made at General Goethals' convenience—it is hoped at the Annual Meeting in December.

Report of Nominating Committee

The Secretary announces the receipt of the report from the Nominating Committee, charged with the duty of nominating candidates for offices in the ensuing year:

June 16, 1917

To the Secretary:

Dear Sir—The Nominating Committee, appointed by the President to submit names of nominees for the various elective offices next falling vacant under the Constitution, report that after considering the communications from the membership and as a result of several meetings of the committee and conferences with the Sections, the following gentlemen have been selected. The committee has communicated with each and has their acceptance in writing of the nominations.

For President for one year:
Charles T. Main, Boston, Mass.
For Vice-Presidents, for two years:
Spencer Miller, New York, N. Y.
Max Toltz, St. Paul, Minn.
John Hunter, St. Louis, Mo.
For Managers, for three years:
Fred A. Geier, Cincinnati, O.
D. R. Yarnell, Philadelphia, Pa.
Fred N. Bushnell, Boston, Mass.
For Treasurer:
William H. Wiley, New York, N. Y.

Respectfully submitted,
(*Signed*) L. E. Strothman,
Willis H. Carrier,
Frederick W. Gay,
A. M. Lockett,
Paul B. Morgan.

Engineering Council

In order to provide coöperation between engineering societies and for the consideration of questions of general interest to engineers and their relations to the public, and to provide a means for united action upon questions of common concern to engineers, the United Engineering Society has established the Engineering Council. It has been instituted with the A.S.C.E., A.I.M.E., A.S.M.E. and A.I.E.E., each having five representatives upon the Council and the United Engineering Society having four representatives. Provision has been made for increasing the number of Societies represented on the Council.

The Council may speak authoritatively for all member societies on public questions of a common interest or concern to engineers.

By-laws governing the activities of the Council have been drawn up and added as amendments to the by-laws of the United Engineering Society.

The representatives on the Council who have thus far been appointed, are as follows:

American Society of Civil Engineers:
Geo. F. Swain — John D. Galloway
Frederick H. Newell — John F. Stevens
Alexander C. Humphreys

American Institute of Electrical Engineers:
H. W. Buck — P. Junkersfeld
E. W. Rice, Jr. — C. E. Skinner
N. A. Carle

American Institute of Mining Engineers:
P. N. Moore — J. Parke Channing
S. J. Jennings — Edwin Ludlow
B. B. Lawrence

The American Society of Mechanical Engineers:
I. N. Hollis — A. M. Greene, Jr.
Charles Whiting Baker — D. S. Jacobus
John H. Barr

United Engineering Society:
Clemens Herschel — I. E. Moultrop
B. B. Thayer — Calvert Townley

ROLL OF HONOR

To the lists already published of those members of the Society who have enlisted in the national service is added the following supplement:

Baldwin, Bert L., Captain, Engineer Officers' Reserve Corps.*
Blood, John Balch, First Lieutenant, U. S. S. Nebraska.
Goetzenberger, Ralph L., First Lieutenant, Ordnance, Officers' Reserve Corps.
Hiles, Elmer K., Captain, Fifth Regiment, Engineer Officers' Reserve Corps.
Howell, Arthur K., Ordnance Dept., Officers' Reserve Corps.*
Hurxthal, Alpheus O., Lieutenant, Ordnance, Officers' Reserve Corps.*
Lynde, Charles C., Engineer Officers' Reserve Corps Camp at Ft. Oglethorpe, Ga.
Maynz, Theodore, Engineer of the Signal Corps, Aviation Department.*
Meixner, Bernard A., Captain, Quartermaster Corps or Ordnance Dept., Engineer Officers' Reserve Corps.*
Morton, Harold S., Reserve Officers' Training Camp at Fort Snelling, Minn.
Mount, Carroll H., First Lieutenant, Ordnance, Officers' Reserve Corps.*
Nickerson, Charles W., Assistant Naval Constructor in the Naval Coast Defense Reserve, U. S. N. R. F., with provisional rank of Lieutenant (J.G.).
Penney, Charles F., Special Service Engineer, Engineer Officers' Reserve Corps.*
Reed, E. Howard, Lieutenant Commander, Torpedo Station, Newport, R. I.
Ritter, Ralph B., First Lieutenant, Ordnance, Officers' Reserve Corps.*
Roberts, Theodore C., Major, Engineer Officers' Reserve Corps.*
Shaw, James W., Captain, Engineer Battalion Wis. N. G.
Streeter, Robert L., Captain, Ordnance, Officers' Reserve Corps.
Vaughan, Aubrey W., Captain Quartermaster U. S. R., Asst. to Depot Quartermaster, Boston, Mass.
Wagner, Frederick H., Major, Ordnance, Officers' Reserve Corps.
Walsh, Walter V., Engineer Officers' Reserve Corps.*
Walsh, William F., Captain, Engineer Section, Officers' Reserve Corps.
Zeiger, Nelson A., First Lieutenant, Ordnance, Officers' Reserve Corps.

* Acceptance of commission pending at date of latest list from War Department.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER AUGUST 10, 1917

THE American Society of Mechanical Engineers is an organization for mutual service of over 8000 engineers and associates coöperating with engineers. The membership of the Society comprises Honorary Members, Members, Associates, Associate Members and Juniors, all elected by ballot of the Council. Application for membership is made on a regular form furnished by the Secretary which provides for a statement of the standing and professional experience of the applicant and requires references from voting members personally acquainted with the applicant. The requirements for admission to the various grades will be furnished upon request.

Below is the list of candidates who have filed applications for membership since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, and those in the third under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by August 10, 1917, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about September 15, 1917.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be somewhat slower than under normal conditions. The first step in the consideration of an application is taken by the Membership Committee, and this committee is composed of busy men, with fewer opportunities to meet together in these strenuous times.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Alabama

DUGGER, Neal, Chief Scale Inspector, Tenn. Coal, Iron & R. R. Co., Ensley
KEISER, Franklin B., President, Keiser-Geismer Engineering Co., Birmingham

Arizona

WHITE, John H., with Ray Consolidated Copper Co., Hayden

California

SWEENEY, Morgan L., Superintendent, Western Pipe & Steel Co. of California., Los Angeles

Colorado

LEHMAN, John L. G., Mechanical and Structural Designer, Great Western Sugar Co., Denver

Connecticut

BEEBE, Robert O., Director, Boardman Apprentice Shops, New Haven
BIXBY, Ezra M., Chief Draftsman, Equipment Engineer's Staff, Winchester Repeating Arms Co., New Haven
EISENWINTER, Edward E., Mechanical Engineer, American Brass Co., Waterbury
GRIFFITHS, William H., Leading Designer, The Pratt & Whitney Co., Hartford
ZACHARIAS, Ernest O., Investigating Engineer, Remington Arms & Ammunition Co., Bridgeport

District of Columbia

NELSON, John H., Associate Engineer-Physicist, Bureau of Standards, Washington

Georgia

THAYER, William B., Engineer and Draftsman, Goldens' Foundry & Machine Co., Columbus

Illinois

ADAMS, Clyde L., Instructor in Machine Shop, Lewis Institute, Chicago
CARTER, William C., Superintendent, Link-Belt Co., Chicago
EDWARDS, Joseph B., President and General Manager, Kellogg Switchboard & Supply Co., Chicago
HAYNES, H[illegible] W., Chief Draftsman, S[illegible] St. Works, American Steel & Wire Co., Joliet
LUNDBERG, Charles, Western Editor, The Iron Age (Nobel School), Chicago
O'DONNELL, Thomas E., Department Head, Western Electric Co., Inc., Chicago
REYNOLDS, George D., President and General Manager, Reynolds Pattern & Machine Co., Moline
SCANLON, Thomas J., Engineer-Custodian, Board of Education, Chicago
SLINING, Byron G., Construction Engineer, Illinois Traction System, Peoria

Indiana

CURRY, John R., Secretary, Hall-Curry Construction Co., Indianapolis
MOHLER, Charles M., Superintendent, Empire Automobile Co., Indianapolis
RUBENKOENIG, Harry, Instructor Car and Locomotive Design, Purdue University, Lafayette
SMITH, Dolph I., Chief Engineer, Hill Pump Co., Anderson
WRIGHT, William H., Superintendent, Citizens Gas Co., Indianapolis

Iowa

GIBSON, William C., Works Manager, Morrison Brothers, Dubuque

Kansas

CHAPMAN, Edmund E., Assistant Engineer Tests, Atchison, Topeka & Santa Fe Railway Co., Topeka

Massachusetts

FISHER, Edward J., Engineer in Charge of Gauge Division, New England Westinghouse Co., Chicopee Falls
FITCH, Charles R., General Manager, The Stanley Works, Bridgewater
HOTCHKISS, Walter A., Mechanical Engineer, New England Drawn Steel Co., Mansfield
LEWTHWAITE, Alfred L., Mechanical Engineer, High Voltage Bushing Engineering Department, General Electric Co., Pittsfield
MERRILL, Charles F., Assistant Chief Draftsman, Draper Corp., Hopedale
MOORE, Carl F., Consulting Engineer, United States Smelting, Refining & Mining Co., Boston

Michigan

ALBRIDGE, Kenneth P., Production Engineer, Parker Mfg. Co., Detroit
McMULLEN, George K., President and Manager, McMullen Machinery Co., Grand Rapids
MAPLE, Omar S., Chief Engineer, Diamond Power Specialty Co., Detroit

Missouri

BOEHMER, Earnst J., Chief Engineer, Rice-Stix Dry Goods Co., St. Louis

BRADLEY, Eugene P., Co-partner, Hester Bradley Co., St. Louis

SCHAUM, Arthur H., Chief Draftsman, Heine Safety Boiler Co., St. Louis

New Jersey

BERTHOLD, George H. E., Superintendent, Rajah Auto Supply Co., Bloomfield

FURMAN, George B., Chief Engineer, L. O. Koven & Brother, Jersey City

GULLIVER, Albert E., Chief Engineer, Trenton & Mercer County Traction Corp., Trenton

KIHM, Otto R., Superintendent, American Can Co., Edgewater

LANG, John F., Superintendent, Oxweld Acetylene Co., Newark

McMILLAN, Daniel G., Power Plant Engineer, Singer Manufacturing Co., Elizabeth

PETERSON, Johann, Superintendent, Manhattan Electric Supply Co., Jersey City

SMITH, Ralph L., Engineer, Machine and Tool Designer, The Celluloid Co., Newark

TAYLOR, Frank E., Master Mechanic, Butterworth-Judson Corporation, Newark Transfer

New York

BANKS, Thomas K., Engineer, Steam Meter Department, American District Steam Co., North Tonawanda

BLOHM, August H., Mechanical Draftsman, The Adder Machine Co., New York

EMRICK, George W., Factory Manager, Eastern Flexible Conduit Co., Brooklyn

FOWLER, Richard E., Mechanical and Sales Engineer, Gerdes & Co., New York

GARDINER, Herbert L., Shop Engineer, Kerr Turbine Co., Wellsville

HULL, George W., Engineer and Chief Draftsman, Halcomb Steel Co., Syracuse

JUDSON, Cyrus F., Engineer, A. J. Coccaro & Co., New York

LEGGO, William F., Assistant to Chief Engineer, New York

McCARTHY, Ralph, Secretary, Corrugated Bar Co., Buffalo

McDONALD, Albert, Production Engineering, New York

MILLER, Franklin T., President, F. W. Dodge Co., New York

MOYER, Melbourne S., Accountant, Barclay Parsons & Klapp, New York

NACKE, Arnold L., Salesman, Manning, Maxwell & Moore, New York

O'CONNELL, John J., Assistant Hydraulic Engineer, Electric Bond & Share Co., New York

POWERS, Richard E., Factory Engineer, Oneida Community, Ltd., Oneida

RILEY, Champlain L., Consulting Engineer in Heating, Ventilation and Industrial Plant Design and Equipment, New York

SMITH, Gershom, Vice-President, The Tabulating Machine Co., New York

SNEDEKER, Theodore A., Assistant Treasurer, The Taft-Peirce Mfg. Co., New York

WOLLHEIM, Walter E., Assistant Mechanical Engineer, Nathan Manufacturing Co., New York

Ohio

ATKINSON, Embry S., Head of Tool Design, Domestic Engineering Co., Dayton

CARLISLE, Tyler W., Assistant Secretary and Treasurer, The Strong Carlisle & Hammond Co., Cleveland

JAMISON, Walter K., Superintendent, Domestic Engineering Co., Dayton

KAISER, Louis T., Mechanical Engineer, Thomas Emery's Sons, Cincinnati

MEHLE, J. H., Manager, Cincinnati Screw Co., Cincinnati

MURPHY, James A., Foundry Superintendent, The Hooven, Owens, Rentschler Co., Hamilton

SCHELLENBACH, William S., Mechanical Engineer, Cincinnati

WARDWELL, Frank W., Jr., President and General Manager, The Wardwell Mfg. Co., Cleveland

Oregon

SULLIVAN, Allan C., Chief Engineer in charge of Estimating Dept., Smith & Watson Iron Works, Cortland

Pennsylvania

AMMERMAN, C. S., Ordnance Designer, Bethlehem Steel Co., Ordnance Dept., Bethlehem

BAUER, George A., Vice President, W. E. Shipley Machinery Co., Philadelphia

BENEDICT, John G., Secretary, Treasurer and Manager Landis Machine Co., Waynesboro

CONE, Martin B., Chief Engineer, Baugh & Sons Co., Philadelphia

COOPER, David M., Mechanical Engineer, National Metal Molding Co., Ambridge

DUNCAN, Harold M., Managing Director, Lanston Monotype Corp., Ltd., of London, England, Philadelphia

FLEISHER, Walter A., Head of Power Department, S. B. & B. W. Fleisher, Inc., Philadelphia

FROELICH, Clarence H., Ordnance Engineer, Bethlehem Steel Co., So. Bethlehem

JACKSON, Elwell R., Mechanical Engineer, Edward Board, Special Machinery and Tools, Philadelphia

SIMPSON, William L., General Superintendent, Eddystone Ammunition Corp., Eddystone

SNYDER, Barney B., Representative and Inspector, Chile Exploration Co., Pittsburgh

TAYLOR, Roger, Engineer, Operating Department, Philadelphia Electric Co., Philadelphia

THOMSON, Clarke, Manager, Clarke Thomson Research, Philadelphia

WALLER, C. B. F., Engineer in Charge of Boilers, Bureau of Water, Philadelphia

ZEHR, Vratislav A., Mechanical Draftsman, Switchboard Engineering Dept., Westinghouse Electric & Manufacturing Co., East Pittsburgh

Rhode Island

PEARSON, Mark, Mechanical Engineer, Bradford Dyeing Association, Bradford

Texas

HUGHES, Howard R., President, Hughes Tool Co., Houston

Virginia

SCHMIDT, Otto da Costa, Chief Engineer, Covington Machine Co., Covington

West Virginia

WINDSOR, Walter A., President, Marietta Manufacturing Co., Point Pleasant

Wisconsin

HEM, Eilif S., Erecting Engineer, Allis-Chalmers Mfg. Co., Milwaukee

MILLER, Roy J., Works Manager, Kohler Co., Kohler

Canada

GAINES, Edward C., Designing Engineer, Dominion Bridge Co., Montreal

McNAUGHT, Frank H., Manager, Maritime Foundry & Machine Works, Ltd., Chatham, N. B.

ROBERTS, Arthur R., Associate Professor of Mechanical Engineering, McGill University, Montreal

Chile

VILLEGAS, Jorge Andres D., Manager Engineering Office, Private Practice, Santiago

Hawaii

EWART, Arthur F., Chief Draftsman, Honolulu Iron Works Co., Honolulu

India

IYENGAR, R. Ramauja, Manager, Sandalwood Oil Factory, Bangalore

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

Alabama

PRATT, Merrill E., With Continental Gin Co., Prattville

California

HARTZELL, Earl F., Draftsman and Engineer, Southern Pacific Co., Bakersfield

Works Manager	3
Miscellaneous	29

NECROLOGY

CHARLES EDWARD HYDE

Charles E. Hyde was born in Bath, Me., November 26, 1855. He attended the public schools of Bath, and, when graduated from the high school there, spent the next three years in the Worcester Polytechnic Institute. The last year of his course was taken in the Massachusetts Institute of Technology. The year after his graduation he spent in Europe for the purpose of examining the shipyards and engine works of the old country, obtaining valuable information in his specialty.

Upon his return he worked as machinist in the Portland Machine Shops, and then as draftsman in the Columbian Iron Works at Baltimore, Md. He was next employed in the drawing office of Cramp's Shipyard, Philadelphia, Pa., and later was chief draftsman for Ward, Stanton & Company, Newburg, N. Y., builders of all types of fast vessels. This last position afforded him the advantage of working with Mr. Stanton, who was noted for his ability as a designer of marine engines.

Returning to Bath in 1884, he entered the employ of the Goss Marine Iron Works as chief draftsman and superintendent, and during his service there he introduced the practical use of the triple-expansion engine, the first to be employed in this country. When this company changed ownership, he was employed by the Bath Iron Works, and was chief draftsman and constructor of the engines of the *Castine*, *Katahdin* and *Machias*.

After leaving Bath he became general manager and president of the New London Marine Iron Works, at New London, Conn. For the last few years he was engaged in business in New York City.

He was a member of the Society of Naval Architects and Marine Engineers and of the Engineers' Club of New York. He became a member of the Society in 1885. He died May 19, 1917.

ROSCOE B. KENDIG

Roscoe B. Kendig was born in Renova, Pa., March 3, 1868. He received his education in the home schools. He began railway work in 1884 as a messenger boy in the employ of the Pennsylvania Railroad. From 1885 to 1890 he served as machine apprentice, and until 1893 as draftsman in Renova. For the next seven years he held the position of draftsman in the office of the superintendent of motive power of the Pennsylvania road, at Williamsport, Pa. In 1900 he was appointed chief draftsman of the Lake Shore & Michigan Southern Railway at Cleveland, O., and in 1904 he accepted the position of mechanical engineer with the same road.

He held this position until 1910, when he was appointed general mechanical engineer of the New York Central lines; and in 1912 he became chief mechanical engineer of the New York Central Railroad Company, which position he held at the time of his death.

He was a significant factor in the development, design and construction of the Collingwood shops of the New York Central Railroad. While he was mechanical engineer of the Lake Shore & Michigan Southern road, the modernization of the locomotive terminal facilities was undertaken under his immediate supervision, and large modern engine houses were erected, many of the features of which have served as a model for later construction of this nature.

He was since 1904 an active member of the American Railway Master Mechanics' Association, and since 1905 of the Master Car Builders' Association. He was a member also of the American Society for Testing Materials and of the Engineers' Club of New York.

He became a member of the Society in 1913. He died May 10, 1917, at Detroit, Mich.

OSCAR PATRIC OSTERGREN

Oscar Patric Ostergren was born in Sweden, May, 1866. He was educated in Stockholm, graduating from the Royal Technical High School with the degree of M.E. in 1888. From 1888 to 1891 he was employed by Treacher, Tenae & Co., civil engineers and contractors, in drafting and surveying a new railroad at Rosario, Argentina. The next year he spent with the Atlas Machine Company, Stockholm, as assistant engineer. He came to New York late in 1892, and was employed in erecting machinery by Robert Hoe & Co. From 1893 to 1896 he worked with Charles D. Mosher, a naval architect of New York, in designing marine engines, and until 1898 he was with Charles L. Seabury & Co., New York City, in the same work. He then became president and general manager of the Ostergren Manufacturing Company, having complete charge of the inventing and designing of liquid-air machinery, internal-combustion engines, and automobiles. From 1902 to 1904 he was with the Fuel Oil Power Company as an inventor and designer of fuel-oil engines. Later he successively held positions with Benjamin Hurd, New York City; Joseph Boyer, Detroit, Mich.; Alger Bros., Detroit, Mich.; and with the Grenetso Engineering Company. He held fifty United States patents on inventions.

He joined the Society in 1910. He died May 11, 1917.

JOHN MITCHELL YOUNG

John Mitchell Young was born in Ardrossan, Ayrshire, Scotland, Sept. 18, 1883. He received his early education in the Glasgow High School for Boys. He then entered the Glasgow and West of Scotland Technical College as a day student, graduating in 1904 from the mechanical-engineering course. He was elected an associate of the college. During his last year in college he carried on investigations having to do with steam turbines, and for a thesis embodying these investigations he received the Montgomerie-Neilson gold medal and prize.

He then entered upon an apprenticeship in the works of William Young & Sons, engineers and ironfounders in Ardrossan. On the completion of his apprenticeship he became a draftsman of sugar machinery with Mirlees Watson & Co., Glasgow. In 1909 he came to the United States, where he took a position as draftsman in the steam-turbine department of the Fore River Shipbuilding Company, Quincy, Mass. He next turned his attention to electrical engineering, and took a position with the General Electric Company, Schenectady, N. Y., as draftsman. Later he took charge of the construction office for the power plant of the Toronto Power Company, Niagara Falls, Ont. He next took up the study of sugar machinery, and became a designer with the Dyer Company, Cleveland, Ohio, and later with the Geo. L. Squier Company, Buffalo, N. Y. For the former company he designed and equipped a complete sugar factory in Louisiana. He became interested in conveying and elevating machinery, and for the next two years he occupied the position of factory equipment engineer and designer with the Otis Elevator Company, Buffalo, N. Y.

He was an associate member of the Institute of Engineers and Shipbuilders in Scotland. He became an associate-member of the Society in 1915. He died March 14, 1917.

AMONG THE SECTIONS

Sections Delegates Meet at Cincinnati

THE Committee on Sections arranged a business meeting at the Spring Meeting at Cincinnati which was preceded by a luncheon attended by the following: President Ira N. Hollis, Past-Presidents Oberlin Smith, W. F. M. Goss and James Hartness; Messrs. John H. Barr and Max Toltz, Managers of the Society; Calvin W. Rice, Secretary; D. Robert Yarnall, chairman, L. C. Marburg and Walter Rautenstrauch, members of the Committee on Sections; also the following representatives of Sections: Atlanta, Earl F. Scott; Baltimore, C. C. Thomas and A. G. Christie; Birmingham, W. P. Caine and J. G. Hatman; Buffalo, C. H. Bierbaum; Cincinnati, Fred A. Geier and John T. Faig; Detroit, George W. Bissell; Erie, Rudolph Conrader and M. W. Sherwood; Indianapolis, W. H. Insley; Milwaukee, Fred H. Dorner; Minnesota, Max Toltz; New Orleans, A. M. Lockett; New York, Ernest Hartford; Philadelphia, D. Robert Yarnall; Ontario, Chester B. Hamilton, Jr.; Worcester, R. G. Williams; and Providence, L. D. Burlingame and A. H. Annan.

Dr. Hollis spoke forcibly concerning the broad principles underlying the Society and its duty to the profession, and particularly of the ideals entertained by the Council for furthering the sections work. Following this speaker, the chairman called for reports from the delegates representing the various sections, and each gave the experiences of his section in turn.

One excellent point brought out and very generally endorsed was that each section of the Society should send to every other section notices of all its meetings, so that each section could be continually posted on just what is going on in the other sections. It was thought that this matter could best be handled by having each section secretary send to the headquarters of the Society twenty-five copies of each meeting notice and having the secretary of the Sections Committee readdress these to the other sections.

A question was raised concerning the amount of money that the Society should appropriate to the sections and it was decided to make recommendations to the Council.

Mr. Rice spoke on the matter of publication of sections material in THE JOURNAL and in Transactions. He complimented the sections on the value of this material received in the past, which had led the Publication Committee to inaugurate a new policy—to devote several issues of THE JOURNAL each year to sections papers. He hoped that each section would contribute its full share toward the best realization of that policy by contributing at least two papers each year for publication. The Sections Committee promised to help the sections toward the realization of this ideal.

D. ROBERT YARNALL,
Chairman Sections Committee.

Sections Meetings

BIRMINGHAM

May 16 A feature of the annual meeting was a two-reel moving picture illustrating the old and new methods of cooking,—coal versus electricity, after which the chairman gave a review of the progress the past year.

During the year the hearty coöperation and support of the two state universities has been enlisted and two representatives from each have addressed the Section. Ten or twelve new members have been secured for the Society through the efforts of the Section, which has also been influential in the organization of the Alabama Technical Association, which includes all the members of the national engineering societies residing in the State of Alabama, of whom there are over two hundred. A combination stereopticon and baloptican machine has been purchased for the use of the members, and it is hoped that greater use will be made of it the coming year.

The officers for the coming year were elected as follows: Chairman, J. H. Klinck; vice-chairman, W. P. Caine; secretary, J. G. Hatman. Paul Wright and R. E. Brakeman were also elected members of the executive committee.

R. E. BRAKEMAN,
Section Chairman.

BUFFALO

June 7 Chester L. Lucas, Mem.Am.Soc.M.E., explained to a large and interested audience the manufacture of 9.2-in. high explosive howitzer shells, illustrating his talk with 2500 ft. of moving-picture film.

Mr. Lucas gave the following interesting data concerning these shells: the weight of each is 250 lb. with an explosive element capable of blowing a hole 50 ft. in diameter in the ground; the cost of the shell was two hundred dollars, while the forging alone costs twenty-five dollars and machining about twenty-eight dollars. It takes about ten man-hours to make one shell.

LOUIS J. FOLEY,
Assistant to Secretary.

CHICAGO

May 18 The first social meeting in the history of the Section to which ladies were invited, proved such a success that it was unanimously decided to hold others in the future.

S. J. Duncan-Clark, war analyst of the Chicago *Evening Post*, gave an intensely interesting address on The War Situation of Today. In order to give the audience the proper perspective the speaker reviewed the incidents leading up to the war, starting with the Kaiser's trip to Palestine in 1898 and the concession given by the Turkish Government at that time to build the Bagdad Railway, which was the first step in the program of the empire that the Kaiser had conceived. Then followed the various intrigues to secure right of way to Saloniki and Constantinople, and the final spark at Belgrade that started the great conflagration. Leading his hearers step by step, the speaker ably reviewed the situation on each front with the final optimistic prediction of victory for the allied democracies over the last great autocracy.

A vote of thanks was tendered Mr. Duncan-Clark and a collection taken for the Red Cross.

The following officers were elected for the coming year: Chairman, Alexander D. Bailey; vice-chairman, H. T. Bentley; secretary, Arthur L. Rice. G. R. Brandon and P. N. Engel were elected members of the executive committee.

THOMAS WILSON,
Section Corresponding Secretary.

MINNESOTA

May 10 K. C. Richards, superintendent of the Minnesota By-Products Coke Company, gave an exceedingly interesting illustrated lecture on coke and its by-products, which was followed by several discussions.

By unanimous vote the following officers were elected for the coming year: Chairman, H. LeRoy Brink; vice-chairman, J. A. Teach; secretary and treasurer, Edward A. Wilhelm.

D. M. FORFAR,
Section Secretary.

NEW ORLEANS

April 2 A general business meeting at which the principal event was the election of officers, resulted in the following elec-

tion [illegible] meeting [illegible] Chairman, H. F. Hudson; secretary, L. W. [illegible]; W. E. Gregory, A. M. Lockett and R. F. Burwell, members of the board of direction.

H. F. Hudson,
Section Secretary.

WORCESTER

Jun. [illegible] After a brief business meeting the delegates to the Spring Meeting gave their reports. Ira N. Hollis, President Am. Soc.M.E., followed with an address.

Dr. Hollis confined his remarks to the war situation, telling of the impressions he had gained while talking with high army and navy officials who accompanied the British and French Commissions to this country. He laid particular emphasis on the fact that this war is a huge business proposition, where the skill of the engineer in handling men and materials is perhaps the most important factor. His remarks touching on the submarine question were particularly interesting and instructive.

The following were elected officers for the coming year: Chairman, George I. Rockwood; secretary, Richard G. Williams. H. P. Fairfield, V. E. Edwards and F. W. Parks were elected members of the executive committee.

Richard G. Williams,
Section Secretary.

Student Branches

CARNEGIE INSTITUTE OF TECHNOLOGY

May 26 The Training of the Engineer was the subject of an interesting talk by J. H. McAlpine, of the Westinghouse Machine Company. The speaker outlined the training required, from the time of entrance to school until the chosen field had been reached.

The following officers were elected for the coming year: President, E. F. Obert; vice-president, E. P. Bateham; secretary, R. G. Brandin; treasurer, E. F. Morgan.

J. H. Davis,
Branch Secretary.

UNIVERSITY OF CINCINNATI

May 22 Several members of the Am.Soc.M.E. were present at the final meeting of the season and addresses were made by Ira N. Hollis, President, Am.Soc.M.E.; Calvin W. Rice, Secretary, Am.Soc.M.E.; William Kent, Mem.Am.Soc.M.E., and Carl G. Barth, Mem.Am.Soc.M.E.

The election of officers was also held at this meeting, with the following results: President, Henry A. Wolsdorf; vice-president, E. H. Schubert; secretary and treasurer, Christ L. Koehler; publicity manager, Oliver F. Gang.

Henry A. Wolsdorf,
Branch Secretary.

UNIVERSITY OF ILLINOIS

May 10 In connection with the Pi Tau Sigma contest, C. Spindler spoke on the Eight-Cylinder Gasoline Engine. Mr. Spindler pointed out the advantages of this type of engine over the four-, six- and twelve-cylinder engines in use for automobiles. The talk was well illustrated with blackboard and chart demonstrations.

May 25 The conclusion of the Pi Tau Sigma contest was reached with the talks delivered at this meeting by J. T. Kelly, on the Heat Treatment of Steel, and by C. Z. Rosecranse, on The Railway Dynamometer Car.

The officers for the coming semester were also elected, as follows: President, H. C. Dieserud; vice president, J. T. Kelly; secretary, L. I. Phillis.

H. C. Dieserud,
Branch Secretary.

LEHIGH UNIVERSITY

May 10 The annual election of officers was the main feature of this meeting, which was purely one of business. The results were as follows: President, J. P. Clymer; secretary, W. A. Bornemann; treasurer, N. Dymtrow.

W. A. Bornemann,
Branch Secretary.

OHIO STATE UNIVERSITY

May 29 This meeting took the form of a banquet, and speeches were made by several faculty members and students. Later, William T. Magruder, Mem.Am.Soc.M.E., spoke on Aviation and illustrated his talk with a large number of lantern slides, which were of much interest to those present.

The officers for the coming year are as follows: President, Paul Bucher; secretary, Fillmore D. Swan; treasurer, E. A. Edwards.

F. E. Smyser,
Branch Secretary.

PENNSYLVANIA STATE COLLEGE

The officers for the coming year have been elected as follows: President, Robert S. Clark, Jr.; vice-president, L. C. Grove; treasurer, Robert K. Cochrane; secretary, P. G. Musser.

STEVENS INSTITUTE OF TECHNOLOGY

May 11. The following officers have been elected for the ensuing year: President, Herbert Peter; vice-president, Raymond S. Mileham; secretary and treasurer, G. Crosby Hiss.

G. Crosby Hiss,
Branch Secretary.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

POSITIONS AVAILABLE

In forwarding applications, stamps should be enclosed for transmittal to advertisers; applications from non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society. Copy for notices must be in hand by the 15th of the month.

DESIGNER on heavy machine tools and similar machinery. Good opportunity for high-grade designer chiefly with drawing-office experience. Salary, \$2,400. Location, Pennsylvania. 40.

TOOL DESIGNER who is resourceful and can follow work through to completion. Technical man with practical shop experience. Salary, \$25 to \$35 per week, according to ability. Location, Connecticut. 185.

SALES ENGINEERS. It is desirable that applicants be young men between 25 and 30 years of age, preferably M. E. graduates of some approved engineering college, and of good appearance; would be expected to undergo a period of probation and training in various offices of company for responsible and higher positions in sales work. If a call cannot be made, application may be made by letter in applicant's own hand writing, stating age, education, previous business training, if any, salary desired, etc. Location, New York. 205.

SALESMEN for power-plant equipment—boilers, engines, forced-draft blowers, pumps and elevators. Commission basis. Location, New York City. 402.

TEACHER for large public institution of the Middle Northwest; strictly high-class man who can conduct classes and give lectures

upon automobiles. Must be technical graduate, with practical experience and not afraid of work. Location, Wisconsin. 421.

INDUSTRIAL ENGINEER—COST ACCOUNTANT. Well-established firm can offer exceptional opportunities for effective and interesting work to engineering graduates who have had substantial experience with modern industrial accounting; special reference to manufacturing costs. In reply state age, education, experience, present and expected salary. Location, Massachusetts. 431.

DRAFTSMAN, capable of designing machines of comparatively large size for boring and milling purposes; also fixtures and tools for use on such machines, to hold and perform work as shown by blueprints. Location, Providence. 525.

EXPERIENCED MAN to take charge of manufacture of soap powder. Salary $30 to start. Location, New York. 563.

DRAFTSMEN for stoker department of concern manufacturing a specialty. Work involves layouts of stoker installations and requires general knowledge of boiler-room work. Salary depending upon man's ability and experience, $25 per week to start. Good draftsman with a little knowledge of this class of work more valuable than good designer. Location, Philadelphia. 565.

PUMP DESIGNER experienced in design and construction of turbine pumps particularly, for large pump manufacturers. Location, South. 581.

DRAFTSMEN AND DESIGNERS familiar with power-plant and factory layouts. Location, Boston. 629.

COMBUSTION ENGINEER experienced in hand and stoker firing of bituminous coal, to study boiler efficiency and other combustion problems. Location, Delaware. 725.

PIPE AND POWER-PLANT MEN wanted by large rubber concern in Ohio. 727.

ENGINEER skilled in handling of materials, to study such work at plants of large industrial corporation; experience with conveying machinery and other mechanical means of transport of materials. Location, Delaware. 782.

TECHNICAL GRADUATE in mechanical engineering, with one or two years' experience in power-house installation and design; should understand piping layout and boiler setting, and be capable of inspecting such work during installation. Location, New Jersey. 865.

DRAFTSMAN who would be interested in investing some money in shop; one familiar with horizontal return tubular boilers and boiler-shop work in general. State age, experience and salary desired. Location, New Jersey. 881.

MACHINERY DESIGNER in turbine department of large electric company. Location, Massachusetts. 894.

MASTER MECHANIC for lead-smelting plant operating blast furnaces and concentrating mills; must be man of strong personality, capable of handling varied classes of mechanics. Give full details of education and experience. Location, Utah. 906.

DRAFTSMAN experienced in factory design and installation of elevator and conveying machinery in general cement-plant work. Location, Pennsylvania. 949.

RECENT ENGINEERING GRADUATE to take up economy studies in pole line and cable-plant construction; one experienced in estimating the cost of such construction given preference. State experience and salary desired. New York concern. 952.

SALESMEN on machine tools to represent large New York exporting corporation in China, Australia and South Africa. 964.

DESIGNERS. Men experienced in steam-engine and turbine work prefered. Location, East Pittsburgh. 967.

DRAFTSMAN familiar with power-house work, installation of equipment, piping, etc., and competent to work out different problems involved from general outline, without need of more or less constant supervision. Salary $25 to $28 per week. Location, New York. 969.

DRAFTSMEN experienced in design of chemical plants or machinery. Salary $30 to $50 per week, depending upon experience and ability of man. Location, New York State. 982.

MECHANICAL ENGINEER with technical education and at least five years' experience at plants manufacturing chemicals; work to be mainly advisory engineering in connection with manufacture of chemicals. Location, Delaware. 991.

MATERIAL SUPERINTENDENT wanted before October 1, by Chicago machinery manufacturer, at initial salary of $200 per month; will be responsible for all factory functions with exception of maintenance of equipment, training hands, tool designing, process inspection; will be immediate subordinate of works manager, and have to compete with one man for advancement. Give education and physical condition in detail; name firms, nature of duties, and number of months spent in each capacity. Location, Illinois. 992

DRAFTSMAN on structural steel. Experience in powder, coal plants, industrial plants, power houses, layout, etc. Location, New York. 1011.

EXPERIENCED PUMP DRAFTSMAN for checking and detailing. Steady work, pleasant surroundings. Location, Middle West. 1021.

DRAFTSMAN for patent office drawings. Salary $25 to $35. Location, New York. 1022.

DRAFTSMAN to make measurements and drawings of machine tools; work will require considerable time and position has good promise for future. Young man desired with technical education and some practical experience, especially in machine-tool work. Location, Buffalo. 1033.

ASSISTANT to mechanical laboratories; prefer technically trained man, who would be able to conduct classes and look after equipment of shops of mechanical laboratories. Salary $120. Location, Brooklyn. 1060.

TECHNICAL GRADUATE capable of undertaking the standardization of materials and processes in large, small-tools manufacturing plant. Must be familiar with chemical and physical testing of metals and other materials, and with mechanical operations. State age, experience and references. Location, Philadelphia. 1087.

DRAFTSMEN having three and five years' experience on boiler and stoker work. Location, New York. 1090.

DRAFTSMAN capable of doing accurate checking on drawings. Location, Virginia. 1093.

METALLURGIST for firm making steel automobile parts, one of the largest in its field; familiarity with modern chemical and metallographical control essential. Must have sufficient initiative to lay out proper methods and the necessary personality to see that those methods are followed. Location, Pennsylvania. 1094.

DRAFTSMAN on piping and general machinery. Salary $20-$35. Location, Connecticut. 1099.

COMBUSTION ENGINEER familiar with large steam plants. Experienced in efficiency work. Location, Philadelphia. 1102.

DRAFTSMAN and ESTIMATORS for work of varied character with large concern. Offers good opportunity for advancement. Location, New Jersey. 1104.

DRAFTSMAN, technical graduate, capable of assuming full responsibility of drawing room, designing tools, fixtures, jigs, gages. One having shop and executive experience preferred. Location, Ohio. 1105.

PRODUCTION SUPERINTENDENT with experience in foundry and machine-shop work. Technical graduate 30-45 years of age preferred. Must be good executive, alert and aggressive in getting work through factory. Shop has approximately 800 men and does all kinds of power-transmission work. Location, Middle West. Salary $3000-$4000. 1106.

TECHNICAL GRADUATE wanted to do mechanical drafting and assist in other work in factory. In answer state age, education, past positions, and salary expected to start. Location, New Jersey. 1111.

MECHANICAL-ENGINEERING DEPARTMENT of a Middle West State college desires applications from men suitable for the position of foreman in machine shop. Successful applicant must have had several years' actual machine-shop work and be familiar with methods of mass production and scientific management. Desirable that he have college training, although not absolutely necessary. Should have had experience as foreman or assistant foreman in some successful shop, and preferably some teaching experience, although this is not absolutely necessary. Prefer young man not over 35 to 40 years of age. Location, Michigan. 1112.

DESIGNER of tools and jigs for large, high-grade factory, to build up a new department. Must have experience in heavy motor-truck work and first-class motor manufacture. An unusually good opportunity for the right man. Give complete information in first letter. Location, Middle West. 1114.

ENGINEER OF TESTS to assume charge of physical testing laboratory of large corporation. Excellent opportunity for technically trained man with from two to four years' experience in testing work. In first letter state age, education, experience in detail and salary expected. Location vicinity of New York City. 1117.

SUPERINTENDENT of boiler house and power house in connection with blast furnace plant. Location Ohio. 1118.

MECHANICAL ENGINEER. Experienced in design of apparatus for chemical plants. Capable of working from rough sketches and other data. Salary $125 per month. Location, New Jersey. 1125.

PRACTICAL EFFICIENCY ENGINEER, not theoretical, for manufacturing company in Ohio. 1126.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be in hand by the 15th of the month, and the form of the notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

WORKS MANAGER or SUPERINTENDENT in moderate-size plant, with view to making permanent connection. Technical graduate, age 31. Wide experience in purchasing materials, employment of all classes of labor, design and layout of factories, and installation of scientific production methods, standardization, and management in various industrial plants. At present employed as industrial engineer by large Eastern manufacturing corporation; work nearing completion with this concern after six years service. G-245.

WORKS ENGINEER or MANUFACTURING SUPERINTENDENT, experienced in modern manufacturing methods, and capable of getting maximum production from equipment and men employed. G-246.

PRACTICAL FOUNDRY MAN. Capable of handling any foundry position. G-247.

CHIEF OPERATING ENGINEER for large central steam-electric power company or holding company. Age 44, married. Twenty years varied experience in steam generation and utilization and design and installation of systems up to 7000 boiler hp. and 2500 kw. Thoroughly conversant with the principles and practice of economy in steam generation and utilization. Good organizer; university graduate. At present employed. References given. Location preferred east of Mississippi River. G-248.

MECHANICAL ENGINEER, with extensive all-around experience, desires change. Charge of mechanical engineering, design or mechanical superintendent. Heavy-machinery and industrial-plant experience. G-249.

SUPERINTENDENT of CONSTRUCTION or MECHANICAL ENGINEER. Specialty: plant construction and maintenance, installation of all power-plant and shop machinery, buildings, foundations, etc. Fifteen years' engineering experience in the West. Technical graduate, age 34. Desires a live job, any location. G-250.

MECHANICAL ELECTRICAL ENGINEER. Columbia graduate. As sales manager or superintendent. At present employed as manager of a very large concern. Experience in internal-combustion engines, gas producers, power installations, foundry and machine-shop practice and marine-power plants. Unusual business and technical training. Fully conversant with French, Italian and Spanish. Minimum salary to start, $4,000. G-251.

MEMBER. Technical, practical, with twenty years' broad experience in design, construction and operation of steam-electric power plants and transmission systems. Good executive. Has shown economy in steam generation with both anthracite and bituminous coal. At present with railroad near New York as engineer of power, light and heat. Desires position as superintendent or chief engineer of electric or steam-power system of large inland power plant, or in ore or coal-mining regions, South or West. G-252.

MECHANICAL ENGINEER. Age 35, married. Wide experience in the design of automatic and general machinery; also experience in general structural work, engine and boiler testing. Familiar with shop methods and following-up work through shops. Desires position with a firm in the Eastern states, preferably Philadelphia. At present employed. First-class references. G-253.

MECHANICAL ENGINEER. Married. Technical education. Thirteen years devoted to experimental work, education, development and production work on internal-combustion engines and self-propelled vehicles. Specialty, internal-combustion engines. Familiar with modern shop practice; can handle men. Open for a position with view of permanent connection. Highest references. G-254.

TECHNICAL GRADUATE, M.E., married, age 27. Shop experience, factory inspector, branch manager, sales experience. Now engaged in safety-engineering work. Desires position as assistant to executive or in sales department. Location preferred in East. G-255.

GENERAL PRODUCTION and FACTORY EXECUTIVE. Age 32, married. American. Technically trained, clean cut and aggressive. Ten years' active experience in layout, organization and supervision of manufacturing projects along efficiency lines. G-256.

EXECUTIVE, MUNITIONS MANUFACTURE. Age 38. Twenty years' experience in almost every capacity, in Corliss-engine manufacture; as works manager recently organized, equipped and operated shop of 1000 men and successfully completed contract for artillery ammunition. Rejected by Engineer Officers' Reserve Corps on account of slight physical defect. Desires position where experience and ability will be fully utilized on the "big job." Present otherwise satisfactory position not directly useful to United States now. G-257.

GRADUATE IN MECHANICAL ENGINEERING. M.I.T. '15. Fourteen months' testing experience with a large electrical concern and some production experience. Desires work along production engineering or works-management lines. At present employed. G-258.

SALES ENGINEER, electrical-mechanical, technical graduate, age 34, married, American citizen. Twelve years' sales experience. Speaks Spanish and Portuguese. At present located in Cuba as consulting engineer, desires position in the United States, preferably in the West. Thoroughly acquainted with Denver, Salt Lake and San Francisco terrritories. Possesses executive ability, has specialized last seven years in electrical machinery, although has thorough knowledge of steam engineering. G-259.

PURCHASING ENGINEER. Presently engaged, would consider change for responsible position. Especially equipped through service with large organizations, and in technical and commercial valuation of materials, electrical and mechanical equipment, machine-shop processes, and building construction. G-260.

YOUNG MECHANICAL and ELECTRICAL ENGINEER. Technical graduate, age 28. Four years with large manufacturer of internal-combustion engines, steam pumps, compressors, gas producers, generators and motors. Two years assistant inspector of gas and electricity in a large city. Practical shop and engineering experience. Sales or engineering position with a future desired. G-261.

DIRECTOR or PRINCIPAL of TRADE or VOCATIONAL SCHOOL. At present head of department technical high school. Six years' practical experience, seven years' teaching. Desires to locate where ability counts and greater opportunity for advancement exists. Present salary $1750. G-262.

CHEMICAL and MECHANICAL ENGINEER. High-grade technical graduate in mechanical engineering who has also had thorough chemical training desires to change from present employment to position in a chemical industry where ability to operate economically, improve and develop methods will be appreciated. Sixteen years' experience, seven in chemical industry. G-263.

EXECUTIVE or ASSISTANT SUPERINTENDENT. Technical education, American, age 36. Practical mechanic, familiar with design of special machinery, tools, jigs, fixtures, etc., for manufacturing duplicate parts on interchangeable system. Twelve years in drafting room, including chief draftsman; six years' shop experience, one as foreman. Salary $2000 per annum. Location preferred, Eastern States. G-264.

WORKS MANAGER or SUPERINTENDENT. American, age 43. Twenty-two years' practical experience in interchangeable-parts manufacture, automatic and semi-automatic machine design and manufacture, power-plant equipment such as valves, piping, brass, gray and malleable iron fittings, tools and fixtures. Successfully held the positions of apprentice, tool maker, general foreman, chief draftsman, mechanical engineer and superintendent. At present employed; best reason for changing. Minimum salary $4,000. G-265.

YOUNG ENGINEER. Technical graduate. Two years' good engineering experience, desires position in engineering sales or purchasing department of manufacturing concern. G-266.

STRUCTURAL and MECHANICAL ENGINEER. Age 33, technical graduate. Six years' experience in designing structural steel and reinforced concrete. At present employed. Desires permanent and responsible position, in either executive or engineering departments, where past experience can be utilized. G-267.

SALES ENGINEER. Technical graduate. Six years' experience in steel work. Three years' experience in selling cast iron and cast steel. Desires position as salesman for large foundry; has large clientele and can produce gratifying results. G-268.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and a Selected List of Engineering Articles

Recent Papers on Engineering Research

In view of the peculiar importance now attaching to engineering and scientific research and the very general desire to know more of the nature, purpose and progress of such work, it has been thought advisable to present here brief synopses of certain of the papers and addresses that have appeared in the last year or so in American and foreign periodicals. The list of articles so abstracted, however, should not be considered in any sense an exhaustive one.

J. J. CARTY CONTRASTS INDUSTRIAL AND SCIENTIFIC RESEARCH

In his presidential address to our sister society, the American Institute of Electrical Engineers, presented at the annual meeting in Cleveland in June 1917, J. J. Carty made an attempt to direct attention to certain important relations between purely scientific research and industrial scientific research and to point out how manufacturers of various types might avail themselves of the advantages of research.

The stupendous upheaval of the European war with its startling agencies of destruction, the product of both science and the industries, Mr. Carty said, has brought about a great awakening of our people, out of which has come a growing appreciation of the importance of industrial scientific research, not only as an aid to military defense, but as an essential part of every industry in time of peace.

Industrial research conducted in accordance with the principles of science is no new thing in America. The Research Department of the Bell Telephone Companies, founded nearly forty years ago, and which is under the direction of Mr. Carty, has grown from small beginnings with but a few workers to a great institution employing hundreds of scientists and engineers. The larger electrical manufacturing concerns have also founded industrial scientific research laboratories, and while vast sums are spent annually upon industrial research in these laboratories, Mr. Carty states that he can say with authority that they return to the industries each year improvements in the art, which taken altogether have a value many times greater than the total cost of their production. Money expended in properly directed industrial research, conducted on scientific principles, is sure to bring to the industries the most generous return.

Industrial scientific-research departments can reach their highest development in those concerns doing the largest amount of business. The conditions today are such that, without coöperation among themselves, the small concerns cannot have the full benefits of industrial research, for no one among them is sufficiently strong to maintain the necessary staff and laboratories. The small manufacturer may, however, obtain the full benefits of industrial research by taking his problem to one of the industrial research laboratories already established for this very purpose. If this be extensively done, such laboratories would be enabled to extend and improve their facilities so as to render better service, but until the manufacturers themselves are aroused to the necessity of action in the matter of industrial research, there is no plan which can be devised that will result in the general establishment of research laboratories for the industries.

In the present state of the world's development there is nothing which can do more to advance American industries than the general adoption by our manufacturers of industrial research conducted on scientific principles.

In the minds of many there is confusion between industrial scientific research and purely scientific research, particularly as the industrial research involves the use of advanced scientific methods. The distinction is to be found not in the subject-matter of the research, but in the motive. Industrial research is always conducted with the purpose of accomplishing some utilitarian end. Pure scientific research is conducted with the philosophic purpose for the discovery of truth and for the advancement of the boundaries of human knowledge. With all this, however, it must be borne in mind that the two are closely interrelated.

While a single discovery in pure science, when considered with reference to any particular branch of industry, may not appear to be an appreciable benefit, yet when interpreted by the industrial scientist—which includes the engineer and the industrial chemist—and when adapted to particular uses by him, the contributions of pure science, as a whole, become of incalculable value to all the new industries.

Mr. Carty strongly emphasized the fact that while discoveries of the pure scientist are of the greatest importance to the higher interest of mankind, their particular benefits are usually indirect, intangible and remote; and he showed how, through the utilization of American universities, means may be provided for an adequate establishment of scientific research in this country. (*Proceedings of the American Institute of Electrical Engineers*, vol. 35, no. 10, October 1916)

W. R. WHITNEY MAKES PLEA FOR RECOGNITION OF RESEARCH AND LIBERALITY TO WORKERS

In an address delivered at the alumni dinner of the Massachusetts Institute of Technology, January 6, 1917, W. R. Whitney, Director of the Research Laboratory of the General Electric Company, made an urgent plea for the better recognition of the value of scientific research work and a more liberal treatment of those engaged in this pursuit. He emphasized particularly how generally the world's greatest discoveries have been disclosed in their first stages by men who were highly trained and experienced in experimenting. The foundations of advance are most often made by such men as experimental-science professors, who with minds skilled in observation and keen in appreciation, have had opportunity to long continue the investigation of some phenomena of nature which they observed.

More chemists and physicists should be trained in our schools than are absorbed in our industries. They are needed much more generally in scientific-research laboratories in the college or elsewhere, where the country's future interests are

concerned. An investigator of the type of Faraday may be safely said to be worth thousands of ordinary men. It is necessary to recognize clearly that the great industrial development has not grown out of an accident or a single observation, but has been the result of painstaking work. It was a professor at Louvain, Minckelers, who apparently started us in the use of illuminating gas. He was not aiming to illuminate houses, but was trying such gases in balloons. He also tried lighting his lecture room by this means. Engineering development from this peculiar discovery did not take place for ten or more years, but it was the inquisitive mind of the trained physicist and chemist which made the engineering possible.

There are many more just such widely interesting developments which only await the careful study of the trained inquirer. Very little or nothing seems to have been accidental. Our position has resulted from gradual accretions of knowledge from many experimenters.

The speaker cited many cases where proper encouragement given to scientists had led to the development of important contributions to engineering in the broad sense of this term. (*General Electric Review*, vol. 20, no. 2, February 1917)

CHARLES P. STEINMETZ WANTS TO SEE RESULTS INDUSTRIALLY USEFUL

Industry, and with it all our modern civilization, depends on engineering, says Charles P. Steinmetz, Chief Consulting Engineer of the General Electric Company. Engineering, however, is nothing but applied science, and science thus is the foundation and scientific research the ultimate means which have created our civilization. Of late the industrial development has been so rapid and the demand for the results of scientific research so great and urgent that universities, which for ages have been the chief homes of scientific research, have not been able to supply it and the industries had to enter the field of scientific research themselves. Besides, universities and educational institutions rather retrograded in scientific research, became submerged in a false commercialism, which figured the output of the college in student-hours per professor, judged efficiency by the percentage of students graduated, and too often wasted the university's best assets, its professors. Thus we find in colleges men who have shown themselves capable as investigators to do scientific research work of the highest order, overloaded with educational or administrative routine and deprived of the time for research work. Private industries rarely commit such crimes of wasting men on work inferior to what they can do; industrial efficiency forbids it.

Thus, when the advance of industry demanded a more rapid extension of our scientific knowledge, scientific-research laboratories were established in the industries and some of them very soon showed their ability to produce scientific work of high character. But these scientific-research laboratories of the industry represent only a part, often a minor part, of the research work done within the industry, and in many places opportunity is afforded for the right men to carry out scientific research. Thus, in the materials testing laboratories of our industrial corporations, in their standardizing laboratories, development sections, etc., research work is being carried out and, as a rule, is encouraged by the corporations.

Under the head of industrial-research laboratories come also the commercial testing laboratories, development laboratories, etc., which have been established and serve the same purpose to the smaller industrial organizations as do the private laboratories to the great industrial corporations.

Theoretical scientific-research work in industrial establishments should be of such character that it may lead to results which are industrially useful. Actually, however, there is no scientific investigation however remote from industrial requirements which might not possibly lead to industrially useful developments. Indeed, experience has shown that it is rare that some industrially valuable results do not follow sooner or later, no matter how abstruse and remote from apparent utility a scientific investigation may appear. To illustrate—when the General Electric Company undertook research work on the electrostatic corona and dielectric phenomena in the air, no immediate or direct benefit could be seen for the company. But before the research was completed it had led to a redesign of practically all high-voltage transmission apparatus and has thus proved valuable in industrial design.

Some kinds of research can be carried out more efficiently by educational institutions, and others by the industries. Research requiring little in facilities, but a large amount of time and attention from research men is especially adapted to educational laboratories, while investigations requiring large amounts of material or of power rather than time of the investigators, are specially adapted to the industries, and often beyond the facilities of the educational institution. The best plan is a division of research between educational and industrial laboratories in accordance with their facilities wherever possible; as, for example, was done in an investigation of the phenomena of the dielectric field by the Consulting Engineering Laboratory of the General Electric Company on one hand, and Johns Hopkins University on the other.

The closer relation of industrial research laboratories to engineering practice leads to a tendency which, in general, may be expressed by saying that in the results of industrial research a probable error is greater, but the possibility of a constant error less. On the other hand, in industrial research the liability exists of limiting the work to such a narrow field that it has little general scientific value. Inversely, in educational research there is sometimes the tendency to generalize beyond the limits justified and so draw wrong conclusions. The quality of the work is about equal in both, and in the industry may vary from scientific research of the highest quality down to investigations which are of little, if any, value.

The essential difference between industrial and educational research, however, is found in their method of publication. The publication mediums of scientific research carried on in educational institutions are the scientific publications, while the publication mediums of the scientific research carried on in the industry are the technical or engineering papers. Unfortunately, a large number of scientists still look on publication in the technical press as unscientific, and as a result a large and steadily increasing part of the scientific research of the country is practically lost to the scientist. In one case certain tables of physical constants, published only a few years ago, neglected to take account of a mass of data on an important subject that had been recorded in engineering proceedings. Such an attitude of our scientists constitutes, in the opinion of Mr. Steinmetz, a serious menace to our Nation's progress. (*General Electric Review*, vol. 20, no. 2, February 1917)

CLAYTON H. SHARP ADVOCATES INDEPENDENT RESEARCH LABORATORIES

In discussing the position of independent laboratories in the engineering industries Dr. Clayton H. Sharp, Technical Director, Electrical Testing Laboratories, New York City, calls attention to the fact, which is becoming more and more clearly recognized, that with the sharpened competition which must

ensue at the close of the war any and all means for increasing our industrial efficiency will be considered with far greater seriousness than ever hitherto.

The great American manufacturing organizations realize the importance of laboratory testing and research and have provided means for carrying it on, but the manufacturers of smaller resources do not make a correspondingly large use of laboratory assistance. This may be ascribed to two causes: First, because they are not so fully aware of their own need for laboratory assistance and of the possibilities of laboratory work in increasing their efficiency; second, because of particular difficulties in securing such laboratory facilities as correspond to their needs.

Pure scientific investigation may be best carried on in the university, but for the adequate pursuit of industrial research work it is necessary to look to organizations constituted differently. The smaller manufacturer might take his laboratory problems to a technical school for solution, but this plan is open to the objection that the funds of the institution, being given for a public purpose, should not be diverted to private ends. Against this it may be urged that it is to the advantage of the technical school to take on a certain amount of industrial work, not only in research but also in testing. Such work necessarily brings both instructors and students into contact with certain practical problems of the outside industrial world, a world of which they know much in theory, but often too little in practice.

There are, however, certain disadvantages in having industrial problems handled by the technical school. The lack of contact with the actualities of practice, on the part of instructors and students who handle the problems, greatly lessens the value of the technical school as an organization for industrial research. The technical-school men are not equipped to consider the problems of cost, of the intellectual and psychological limitations of workmen, of transportation, of market conditions, of company policy, of technical and commercial usage in the field, any or all of which may have their influence on the result.

It is the independent laboratory that has to provide for the smaller manufacturer what the private laboratory does for some of the great corporations. To fulfill these functions properly, the independent laboratory must be adequately supported, properly manned and abundantly equipped. Its staff must be organized on particular lines. Its engineers must be familiar with the practical and commercial features, as well as the technical details of the work which they encounter. It must include physicists and chemists accustomed to look at the fundamental features of the problems presented. The fees charged by such a laboratory must be adequate to cover not only all expense but also to yield a sufficient profit as well.

In return the laboratory must deal with its clients in a highly confidential manner, conserving individually all of the results of the work for which they are paid. It must be prepared to turn over to its clients the inventions and patents which are the direct outcome of any specific piece of work.

The equipment of such a laboratory must be extensive to enable it to handle the great variety of work afforded to it. A very large supply of electrical power is an absolute requisite. To some extent a laboratory of this sort must possess from its very inception a considerable investment for its equipment. All this makes the establishment of such laboratories a matter of considerable difficulty, notwithstanding the great importance of the results which they may achieve for the industry. (*Journal of the Franklin Institute*, vol. 183, no. 2, February 1917)

ALBERT H. HOOKER CITES NIAGARA FALLS WORK

In a paper presented before the American Electrochemical Society on February 11, 1916, Albert H. Hooker, Works Manager of the Hooker Electrochemical Company of Niagara Falls, New York, presented a paper on Niagara, the Commercial Research Laboratory of the Nation.

In this paper the very significant statement is made that when the Niagara Falls Power Company started their tunnel about 1891, not one of the products now made by the company's use of power was then known to commerce. Aluminum, carborundum, alundum, silicon, artificial graphite, calcium carbide, cyanamide, various ferroalloys, sodium, chlorine, chloroform, etc., are all commercial products of the last 25 years, most of them having been developed through the impetus given by this Niagara Falls power development.

The vast importance of these products has scarcely been fully realized. Carborundum, alundum, aloxite, crystolon are all artificial abrasives used in modern grinding machinery for the manufacture of automobiles, guns, shells, shoes and for the grinding of tools. There is hardly an industry where the tremendous decrease in production and increase in cost would not be felt, were we without these artificial abrasives produced by the electric furnace at Niagara.

There are many vast problems in this connection and not in a day, a month, or even a year can these problems be worked out, the equipment developed and installed, and above all the workers trained. (*Metallurgical and Chemical Engineering*, vol. 14, no. 5, March 1, 1916)

MARSTON T. BOGERT DESCRIBES WORK OF CHEMISTRY COMMITTEE OF NATIONAL RESEARCH COUNCIL

In a preliminary statement to the American Chemical Society, M. T. Bogert gave some data on the National Research Council and its Chemistry Committee.

The main object of the National Research Council is, as its name suggests, to aid the cause of scientific research in every way possible. During the period of the Civil War the Federal Government often felt very keenly the need of expert advice in scientific matters of all kinds, and it was to meet this end that Congress, on March 3, 1863, by special enactment created the National Academy of Sciences. The present war has again shown with startling vividness to what extent the military power of a nation is dependent upon its scientific and industrial preparedness. The first step in this direction was made by the Naval Consulting Board of the United States with the coöperation of the 30,000 members of the great national engineering and technical societies. This board took a census of our industrial resources. The next step necessary was a proper classification of the census of the scientific-research resources of our country, and the body to whom the Government naturally turned for assistance was again the National Academy of Sciences. This latter, at the request of the President of the United States, has organized the National Research Council.

As regards the work of the Chemistry Committee, the present report calls attention to the fact that the vast majority of important scientific problems concern more than one science. There is, therefore, great need of some agency which will aid research workers, who wish to do so, to coöperate more intelligently. It is believed that the general committees of the Council can perform this service acceptably and thus act as accelerating catalysts to the growth and development of our science by becoming great clearing houses for the chemical research work of the country and authoritative headquarters

for information likely to be of value to the individual investigators, to our industries, and to our Government.

It should be stated most emphatically that the object of the Council and its committees is to assist, and not to direct. It has no desire or intention to interfere in the slightest with the freedom or initiative of the individual investigator, or to attempt to "organize and coordinate" him. In fact, the Chemistry Committee prefers not to receive any information which cannot be disclosed to any loyal American chemists. Those who are willing to place at the service of our Government confidential information of any kind should communicate direct with the secretary of the appropriate department or with the Director of the Council of National Defense.

The report proceeds to point out in which way the Council can hope to accomplish what is not being adequately cared for already by existing agencies. In the first place, the Council with the assistance of the Research Committees it is organizing in all of our leading educational institutions, can aid in obtaining for an investigator better recognition on the part of the community and of his own institution and an amelioration of his lot, by securing for him more freedom and better equipment for research, adequate assistance and a living wage. A deliberate and carefully considered recommendation by an authoritative body, such as the National Research Council, with the weight of the National Academy and of the Federal Government back of it and based upon information gathered by committees of leading experts, cannot be lightly passed over and is apt to be productive of results.

Thus the Council might well point out to our educational institutions the shortage of men properly equipped for high-grade research work in science; the fact that young men are being drafted into the industries, by present high wages, as soon as they are graduated and before they have had any special training in research; that the future is being handicapped by the loss to these same industries of so many inspiring teachers and investigators; the need of new advanced textbooks and reference works in science in our own language; of colleges and schools devoted to highly specialized training and instruction in relatively narrow fields of pure or applied science; and of great scientific research endowments, like the Rockefeller Institute of New York, and the Mellon Institute of Pittsburgh.

One of the first tasks confronting the Council is that of securing an accurate and properly classified list of the scientific investigators of the country; showing where they are located, in what lines of research they are interested, and how their work can be aided and encouraged.

The plan adopted for accomplishing this is to send out a questionnaire to all our educational and research institutions, and it is particularly requested that all chemists who receive such questionnaires from the American Chemical Society, the National Research Council or from any of their committees, will fill them out and return them promptly to the proper office. The data received in reply will be sorted out and classified in the office of the general committee and then forwarded to the chairmen of the appropriate sub-committees. The chairmen of these sub-committees will thus be put in possession of all information relating to their own particular fields, and will be then in a position to determine how best to help their fellow-workers. Reports on the situation in each branch of science will come periodically to the office of the general committee, together with recommendations and suggestions from the heads of these sub-committees concerning important investigations now under way or which should be initiated.

The committees of the Council are already of great assistance in bringing together the problem and the man best qualified to attack it. Both the Government and our industries are frequently entirely at a loss as to who are the proper men to consult when important research problems confront them. On the other hand, many skillful investigators are delighted to find that certain of these same problems, of whose very existence they have remained in blissful ignorance, fit in admirably with the kind of research work they enjoy most, and the fact that the problem has direct practical bearing imparts to the work added zest and charm.

Another form of coöperation which will help in meeting this same difficulty is that inaugurated by the University of Illinois and which has since been introduced at other institutions giving instruction in chemical engineering. Briefly stated, it consists in having the chemical engineering students, for their summer work, manufacture fine chemicals for sale to investigators in other institutions. The students thus get practical experience in the manufacture of chemicals, receive pay for the work, and the product is sold at its approximate cost. This does not in any way invade the territory of the commercial manufacturing chemist, for the reason that the chemicals so produced by the universities will be only those which are used in such small amounts that they are of no interest to the manufacturer. Through the Chemistry Committee of the Council, duplications in this work can be reduced to a minimum, each institution producing a different list of research chemicals for which it has provided the requisite equipment, and the Committee can then tell an investigator at once to which institution to apply for the special chemical desired. (*Journal of the American Chemical Society*, vol. 39, no. 5, May 1917)

A RESEARCH DEVELOPMENT IN ENGLAND

As an illustration of the development of research in England, we read in *The Engineer* for February 16, 1917, that the Advisory Council of the Government's Department of Scientific and Industrial Research has added to the list of its technical committees a Standing Committee on Glass and Optical Instruments.

The Committee met on December 11, and having regard to the urgency of the problems requiring investigation in respect to these essential industries, appointed a series of sub-committees to which various special problems were referred. Among these problems the more important are:

- *a* Raw materials for glass and glass making
- *b* Optical properties of a large range of glasses
- *c* General physical and chemical properties of glass and glassware for scientific and industrial purposes
- *d* Testing and standardizing of glassware
- *e* Workshop technique
- *f* X-ray glass properties
- *g* Optical calculations and lens designing
- *h* Optical instruments
- *j* Translation of foreign works on optics.

This brief description indicates certain lines of investigation which have been brought forward. The Standing Committee does not propose to limit itself to these subjects, but is prepared to consider and report upon the necessity for investigation in other directions, relevant to its terms of reference. Manufacturers who have experienced difficulties requiring investigations for their solution in connection with the subjects of glass and optical instruments or who desire to make suggestions for special researches on these subjects are invited to communicate in the first instance with the Secretary of

the Research Department, Great George-street, Westminster, S. W., who will direct the correspondence into the appropriate channels for attention.

ALFRED SAXON FORESEES AGREEMENT ON RESEARCH NEEDS

In a paper read before the Manchester Association of Engineers on February 10, 1917, Alfred Saxon, who is a representative of the society in question on the British Standing Committee on Engineering, said that, with reference to industrial research in mechanical engineering, the scheme was likely to take the form of certain well-defined sections of the trade being brought together and agreeing as to the researches that were the most necessary and desirable, each firm joining being asked to contribute towards the cost, assisted by a government grant. He considered that the value of the scheme to practical mechanical engineering would depend largely upon whether the government was prepared to assist until the research schemes became self-supporting by the contributions of the firms themselves. He urged that all firms would act wisely by making provision in future for an outlay on research work as a standing charge. Inasmuch as mechanical engineering was the key industry to all the industries, the need of scientific research to assist in the creation of new ideas and new methods and to reduce manufacturing costs and prevent waste of material was overwhelming. (*The Engineer*, vol. 123, no. 3190, February 6, 1917)

ROBERT KENNEDY DUNCAN AND HIS NOTABLE RESEARCH PLAN

No synopsis of papers on industrial research in America would be complete without a quotation from some work by the late Prof. Robert Kennedy Duncan. First as professor at the University of Kansas, then in a broader field of activity at the University of Pittsburgh, Professor Duncan did yeoman work in making available for the American industries such means of research as there were. His work was largely responsible for the establishment of the Mellon Institute of Research at the University of Pittsburgh, which not only did and is doing useful work itself, but served as an example in the recent establishment of a system of research coöperation between technical schools and industries in Australia.

In 1906 Professor Duncan published his Chemistry of Commerce, the object of which, as he stated in the introduction, was to convince the manufacturer, through instances taken here and there, how absolutely applicable is modern science to the economy and progress of manufacturing operations.

At that time he preferred against American industries the grave but nevertheless largely true charge that in our country, astonishing to say, success in many cases has been achieved actually by working in accordance with the motto, "Save at the spigot and waste at the bunghole."

Professor Duncan early realized the tremendous importance of the German system of research as an element in industry and often expressed his ideas in a striking manner. "The Badische Anilin und Soda Fabrik of Ludwigshofen am Rhine" is a name to conjure with in Germany, and no robber castle on that historic river was ever more dreaded than is this modern fortress of industry by those against whom it is commercially and inimically inclined. It was in England in 1831 that Peregrin Phillips discovered that sulphur dioxide and air would unite with the most agreeable ease in the mere presence of platinum. However, nothing came out of this discovery in England, because there was no sympathy there between learning and manufacture. In Germany, on the other hand, there was no tariff wall against English ideas and the matter was taken up. Difficulty after difficulty arose, and plan upon plan went to the scrap heap. They found they were using little air when they ought to use much; they found they were using heat when they ought to use cold; they found that platinum was being constantly poisoned by impurities in the roasted gas. But after an enormous expenditure of knowledge and time and labor and money, they won. The roasted sulphur gas and air are scrubbed and dried and cooled and passed over platinized asbestos, only to be collected therefrom as sulphuric acid—more than 200,000 tons in 1904. And all this has added significance from the fact that here a highly valuable product is obtained through the utilization of a by-product, the waste sulphur from the zinc blend. Here the enormous dividends paid by these companies attest the profitable nature of the application of pure science to industry.

The industrial fellowship was one of the solutions of the problem as to how the American manufacturer might secure the benefits of the highest grade of research at a reasonable cost. The scheme proposed was to have a special research department in the university. The company which desires a certain problem investigated endows an industrial fellowship or fellowships for a period of one or more years. The exclusive purpose of such fellowship is the discovery of improvements in the particular branch in which the donor is interested, and the holder of the fellowship gives his whole time and attention to that particular problem.

The fellow is appointed by the university authorities. He is a member of the university and pays all regular fees, works under the advice and direction of the professor in his department, and periodically forwards through this latter the reports of the progress of his work to the industrial company which donated the fellowship.

All the discoveries made by the fellow during the tenure of his fellowship become the property of the company, subject to the payment by them to the fellow of one-tenth of the net proceeds arising from such discoveries.

The concluding words of Professor Duncan's book may be worth recalling at the present time:

"Everywhere throughout America, wherever there is the smoke of a factory chimney, there are unsolved, exasperating, vitally important manufacturing problems—problems in glass, porcelain, starch, tanning, paints, drugs, meats, iron, oil, metallurgical products—problems wherever man deals with substance. It seems clear that these problems can best be answered by combining the practical knowledge and the large facilities of the factory with the new and special knowledge of the universities, and by making this combination through young men who will find therein success and opportunity.

"A Temporary Industrial Fellowship does this: it affords a young man every incentive to lay his hands on the vast body of correlated knowledge called Science, and to make it subserve the practical needs of the human race."

The Society for the Promotion of Engineering Education has cancelled its meeting planned to be held at Northwestern University, and will hold its 1917 annual meeting in Washington, July 6 and 7, in connection with the Educational Committee of the Advisory Commission of the Council of National Defense. The topic of the meeting will be The Relation of the Engineering Schools to the National Government during the Present Emergency.

New Tidewater Tin-Plate Plant

It is expected that the first unit of the new tin-plate plant now being built for the Bethlehem Steel Company at Sparrows Point, Maryland, will be ready for operation by July 1.

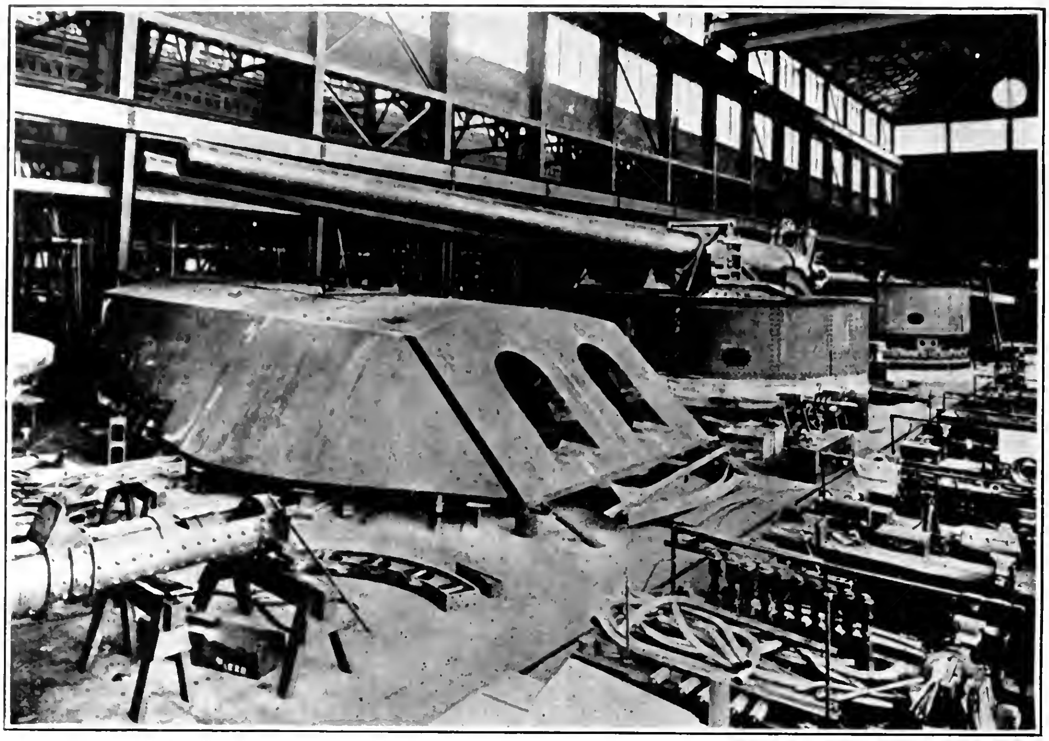
This plant forms part of the tremendous construction program recently undertaken by the Bethlehem Steel Company in various sections of the country. The Sparrows Point plant was formerly operated by the Maryland Steel Company and the tin-plate works will form another link in the growing chain of steel products manufactured by the Bethlehem Steel Company. It is laid out for an eventual production of 2,000,000 base boxes annually. The initial unit of 12 mills now nearing completion will have, however, a production of only 1,000,000 base boxes of tin plate a year.

The buildings are of permanent and fireproof construction and of generous size throughout. Although only twelve mills are being installed at present, the buildings, foundations, etc., have been completed for the eventual twenty-four mill layout.

Some of the drives used are of considerable interest. The hot mills, which are of very massive construction, are divided into two main groups of six each, each group being driven by a 1200-hp. motor designed to operate on 2200-volt, 25-cycle alternating current. The motors are connected to the hot-mill spindles by means of cast-steel cut helical reduction gears. The speed reduction is eight to one.

The cold-rolling department consists of 12 stands of 24 by 36-in. cold rolls driven in tandem of three by a rope drive and a 1200-hp. motor. The Wuest herringbone reduction gear is interposed between the motor and the rope pulleys. The rope drive is inserted in the power-transmission system in order to be sure that the sheets will leave the mill with the most desirable surface possible, and it is believed that a rope drive tends to give a better surface to sheets than a rigid gear drive.

In connection with the above description, attention is called to the accompanying photograph, very recently taken (Underwood and Underwood) and not published elsewhere, of the gun-machinery room of the Bethlehem Steel Company.



Underwood and Underwood

GUN-MACHINERY ROOM OF BETHLEHEM STEEL COMPANY

Work of American Colleges and Universities During the War

The report has been received of a meeting held in Washington, May 5, of college presidents, called by Dr. Hollis Godfrey, Chairman of the Advisory Commission of the Council of National Defense on Science and Research, including Engineering and Education. The object of the meeting was to formulate a comprehensive policy for coöperation between the higher institutions of learning and the Government and to determine a general policy to be pursued by the American colleges and universities, so that their resources would be available, to the fullest extent, for Government service.

In a statement of principles issued, it was held, first, that all young men below the age of liability for selected draft who could avail themselves of the opportunities afforded by our colleges should do so in order that they might later be able to render the most effective service. Second, that the colleges should consider the advisability of dividing the college year into four quarters of approximately 12 weeks each, and that, where necessary, courses be repeated at least once a year so that the college course might be best adapted to the needs of food production. Third, that students pursuing technical courses, such as engineering, would render more valuable service by continuing their training than if they were to enroll in military or naval service before graduation. Fourth, that the colleges should include as a part of their course of study, teaching in military science in accordance with the provisions of the National Defense Act of June, 1916.

Resolutions were passed looking to coöperation between the Government and the colleges, by which means the latter would

be kept informed of the plans of the Government in its various departments for the prosecution of the war, in so far as they concern the work of the colleges; and of the extent and type of technical or military training which it may seem desirable to the Government that the colleges should undertake.

A committee was appointed by the Chairman to serve as a special section on education of the Committee on Science, Engineering and Education of the Advisory Commission, which took preliminary steps toward the accomplishment of results indicated by the resolutions at the main meeting.

Notes from the Engineering Colleges

Equipment of Laboratories—Investigations in Progress—Changes in Curricula

BELOW is a continuation of the review of professional work being undertaken at the engineering colleges. The articles contain information regarding (1) characteristics of laboratory equipment, (2) tests or researches under way or in prospect, (3) important changes in curricula.

The articles will be concluded next month.

Armour Institute of Technology

Equipment: The laboratory equipment differs very little from that of institutions such as Cornell or the University of Illinois. Special equipment for research work in automotive engineering, refrigeration, heat transmission through insulating materials, fan blowers, and lubrication.

Experimental Work: Specialization in testing automotive engines and appliances; work for commercial concerns; method of testing internal combustion engines; testing various materials for use in connection with Government work.

Brown University

Equipment: Usual college apparatus, to handle mechanical tests of materials up to 400,000 lb. in tension, compression and cross bending and to 60,000 in.-lb. in torsion. Especially well equipped with auxiliary measuring apparatus and with means for measuring power.

Experimental Work: Determination of causes affecting precision of machine tools; study of electric high-temperature heating furnaces for industrial purposes. Plans under consideration for closer coöperation in matters of instruction between the University and the industrial establishments of the community.

Curriculum: Entire revision of the engineering curriculum has been authorized by the Board of Fellows to go into effect next fall, as the result of a careful study by a large committee of engineers and educators. The new course is designed to develop the broader type of engineer. It has come about as a result of the demand for engineers trained in the fundamental sciences and their applications, with power to express themselves with clearness, accuracy and force; and with a knowledge of human relations to enable them to enter executive offices and industrial organizations as well as to direct the work of construction ordinarily expected of an engineer.

Under the new curriculum the student may either take a course which will fit him for a broad choice of positions; or, if he is to specialize, he can postpone specialization until he has had an opportunity to determine the field for which he is best fitted. He will not be forced to an early decision as to the particular branch of engineering which he is to pursue.

Throughout the course emphasis is placed on the fundamentals of science and engineering together with such applications as may be necessary to drive home the principles and give the engineering point of view. Courses which give mainly information easily secured while on practical work after graduation are either eliminated or made elective. Subjects fundamental to all branches of engineering are required of all students, but opportunity will still be given for specialization in civil, electrical and mechanical engineering for those who desire it. Engineering courses are introduced in the freshman and sophomore years to parallel the courses in mathematics and physics and to give an opportunity to apply the theories to actual problems. Foreign languages as a requirement are eliminated, although they may be elected. The course allows considerable flexibility in the choice of subjects. The requirements are as follows:

Freshman Year: Trigonometry, analytic geometry and elementary calculus; mechanical drawing, first semester; descriptive geometry, second semester; surveying and engineering mechanics; rhetoric and composition; chemistry or substitute; during part of the summer vacation a course in either surveying or shop work will be required.

Sophomore Year: Differential and integral calculus; economics and either social or political science; physics, mechanics and graphics, English or approved substitute.

Junior Year: Mechanics and structures; electrical engineering; heat and power; materials of engineering, first semester; hydraulics, second semester; approved elective.

Senior Year: Engineering economics, report of special investigation, two engineering electives, two approved electives.

The electives include advanced surveying; railroad engineering; geodesy; highway engineering; structural design; water supply and sewerage; advanced electrical engineering, direct and alternating currents; traction engineering; transmission engineering; shop practice, organization and management; machine design; power plant engineering; gas power engineering; experimental engineering; conference courses in heating and ventilation; refrigeration, fire protection, etc.; mathematics, chemistry, physics; French, German, Spanish or Portuguese; English, public speaking, history, philosophy, social and political science and economics; the entrance requirements are unchanged.

Kansas State Agricultural College

Equipment: For testing materials, a 200,000-lb. Olsen universal testing machine, a 250,000-in.-lb. torsion testing machine, a 100,000-lb. and a 50,000-lb. Riehlé testing machine, a 10,000-lb. beam testing machine, cement and concrete testing equipment, two impact machines, a hardness testing machine, equipment for testing bituminous road materials, etc.

The equipment includes also a number of dynamo electric machines, a compound steam engine of 50 hp., 12 steam engines with different types of valve gears, three steam turbines equipped with condensers; pumps; a Smith suction gas producer, which supplies gas to a 25 hp. Foos gas engine and can be operated either with producer gas, natural gas, water gas or with light and heavy liquid fuels; 30 other gas and oil engines, one 3½-ton Frick compression machine for refrigeration, one ½-ton York compression machine and one 2½-ton horizontal compression machine, equipment for testing trucks and traction engines.

Research Work, Tests: Concrete and aggregates, insulation for electrical conductors, lightning arresters, machine tools, heating and hardness tests on metals, Kansas molding sands.

Investigations: Refrigeration; sewage disposal; uses of electricity in the home; oil engines and oil traction engines, automobile motors, lubricating oils for automobiles, properties of paints, thermodynamic investigations on steam and internal-combustion engines. Members of the engineering faculty are encouraged to take up investigations of value to the profession, which are carried on under the auspices of the engineering experimental station.

Curriculum: The engineering courses are being revised as the college is changing from the three-term plan to the semester plan. In this connection a study has been made of the time devoted to the various subjects in thirty of the leading engineering colleges. In the new courses of study these results will be incorporated.

Lewis Institute

The Cement Users' Association makes use of the strength of materials laboratory for its investigations in cement and other materials entering into concrete construction, while the Institute continues to use the laboratory for the purposes of instruction. This arrangement has proved very satisfactory. The students are showing interest in the work of the laboratory, and there seems to be a stimulus to good work in the presence of this busy, scientific workshop.

New Mexico College of Agriculture and Mechanic Arts, School of Engineering

Equipment: This is a typical land grant college, with emphasis in its course in experimental and extension work in agriculture and engineering. The agricultural experiment station is conducting work regularly along improvements in methods and efficiency in this state. The organizing of an engineering experiment station is now under consideration.

Experimental Work: Considerable experimental work was done on arc welding and testing of brick; it is hoped materially to increase this research work and particularly to do work of help to the United States Government.

Curriculum: In addition to the regular engineering courses, it is planned to give a six weeks' practical course in highway construction and concrete, to further the good road movement; also to give a practical six weeks' course in electricity, automobile mechanics and tractor operation, the use of the tractor in New Mexico being still in its infancy. A one-year short course in automobile mechanics proved very successful last year.

Oregon Agricultural College

Equipment: Apparatus for testing materials, cement, etc.; highway, hydraulic, steam, oil and gas engines; fuels and oils; metallography of iron and steel, including some special apparatus for tests in power transmission, on insulating materials, and on heating and ventilating equipment.

Experimental Work: In addition to the regular instructional work this department does the laboratory work for the Oregon State Highway Department and during the past year the majority of the special tests have been on Oregon highway and bridge materials.

Pennsylvania State College School of Engineering

Equipment: A thermal testing plant which includes refrigerating apparatus, and a heating system; a separate building thoroughly insulated in which is a second insulated compartment for tests of the transmission of heat through simple and compound walls (additional apparatus is being installed to provide for accurate automatic regulation of temperatures), and a steam laboratory equipped for the testing of steam, gas, kerosene and oil engines of various types and capacities. There is also a completely equipped flour mill for experimental and research work, as well as for class instruction, and a separate building equipped for the study of causes of explosions in flour and cereal mills, with firing apparatus, instruments for the detection of static electricity, and special apparatus for the prevention of the propagation of flame from mills to storage bins.

Experimental Work: On the loss of heat through glass as influenced by wind velocity, humidity and difference in temperature; explosiveness of various mixtures of flour milling materials, and possible sources of ignition; economy of oil engines of the 20-hp. semi-Diesel type; on the life of various types of electric lamps; and relative fire protection offered by unpainted board surfaces, surfaces painted with common white lead and oil, and surfaces painted with a fire resisting special paint.

The study of the explosiveness of various flour-mill dusts has shown that where separate sources of ignition are provided, such as electric arcs, in the attrition mill, explosions could be produced at will, and of an intensity that seemed to indicate that the destructiveness would depend upon the quality and quantity of material ignited.

Rose Polytechnic Institute

Equipment: The institute has just completed a very successful campaign whereby means have been provided for the erection and equipment of its new plant, which contemplates a removal of the entire institute within the next two years. The new site lies two miles outside of the city limits, and will occupy a campus of one hundred and twenty-two acres. The plan to be carried into effect provides for complete new equipment as well as new buildings.

The laboratory equipment includes a 200,000-lb. Olsen testing machine, a 100,000-lb. Riehlé testing machine with recording apparatus, a 32,000-lb. special testing machine, a 100,000-lb. beam-and-column testing machine, a 10,000-lb. chain-, rope- and wire-testing machine, a 4-in. continuous torsion-testing machine, three cement-testing machines with complete apparatus for cement testing, wire-testing machine for elasticity, etc., an alternating-stress machine, continuous and integrating indicators for steam and gas engines, indicator-testing machines, transmission and absorption dynamometers, tool-cut dynamometer, 6-in. journal-friction machine, traction dynamometers for cars and engines, Kelvin electric balances for standardizing wattmeters, volt and ammeters, electrostatic voltmeters up to 100,000 volts, apparatus for testing insulating materials; testing instruments and transformers; dividing engine and comparator for length standardizing.

Experimental Work: Construction and test of hydraulic shunt flow tube; study and comparison of the road resistance of various road-building materials, especially with reference to automobile traffic; relative strength of square and filleted corners; effect of humidity conditions on the power production of gasoline engines; experimental investigation of aluminum-

chromium alloys; efficiency test on internal combustion engines; electric hysteresis test and losses in iron; strength tests on bridge members; utilization of wood waste; utilization of city garbage.

SIBLEY COLLEGE, CORNELL UNIVERSITY

Equipment: The mechanical laboratories consist of the following:

The Materials Testing Laboratory, which is equipped for tension and compression tests with an Olsen 300,000-lb. machine, a Riehlé 100,000-lb. machine, a 200,000-lb. Emery hydraulic machine; for transverse tests with a Riehlé machine of 200,000 lb. capacity and a Fairbanks machine of 10,000 lb. capacity. There are two Thurston autographic torsion machines, one Olsen torsion machine of 200,000 in.-lb. capacity, and two Upton-Lewis fatigue testing machines.

The Steam Laboratory, which comprises a 150-hp. triple-expansion Allis-Corliss engine and several smaller engines. There is a 35-kw. horizontal Curtis turbine and a 15-kw. De Laval turbine, an Ingersoll-Rand compressor and three air-brake pumps of different types, a 150-hp. Babcock & Wilcox water-tube boiler of marine type, and one 100-hp. Babcock & Wilcox water-tube boiler of standard type, an 80-hp. Heine water-tube boiler and a 25-hp. Roberts safety boiler connected with a Foster independent superheater.

The Gas Engine Laboratory, including gas engines, gasoline engines, and hot-air engines.

The Hydraulic Laboratory, containing centrifugal pumps, water wheels and hydraulic rams; water meters and other auxiliaries.

The Oil Testing Laboratory, Refrigeration Laboratory, Cement Laboratory, Fuel Testing Laboratory, which are similarly equipped.

The electric equipment includes a Dynamo Laboratory, Standardizing Laboratory, and a Wireless Laboratory.

Work Shops include a foundry occupying floor space of about 4800 sq. ft., a forge shop with the usual equipment of standard forges and small tools, a pattern shop with floor space of 8440 sq. ft.; the machine shop has the same floor area as the pattern shop. It is equipped with an electric traveling crane and representative modern machine tools. A part of the workshop equipment is installed to illustrate the latest practice in production with specialized labor-saving machinery.

WASHINGTON UNIVERSITY (ST. LOUIS)

Equipment: Laboratories are equipped to do research work on fuels, gas and steam appliances, automobiles, etc., and especially equipped for testing cutting tools.

Research Work: Tests have been made on steam-turbine nozzles, automobiles, kerosene carburetors, and high-speed steel cutting tools, but the work was not all completed owing to the seniors carrying on the work being excused for military duty. In the tests on cutting tools particular attention was paid to the effect on the life and power of the tools when the lip and front angles were varied. In cutting soft steel the best results were obtained when using a lip angle of 25 deg. and a front angle of 14 deg. In the carburetor tests it was possible to operate a 9 by 11-in., 300 r.p.m. two-cylinder, four-cycle Bruce-Macbeth gas engine on various mixtures of kerosene and water and of kerosene and gasoline. The experiments were not carried far enough to arrive at any definite conclusions as to the best mixtures to use.

SHEFFIELD SCIENTIFIC SCHOOL, YALE UNIVERSITY

Equipment: General teaching and research laboratories in physics, chemistry, mechanical engineering, electrical engineering, mining engineering, cement testing. The mechanical-engineering laboratory is equipped to handle problems relating to motor vehicles, steam and gas engines, house-heating boilers, and the testing of materials. The mining laboratory has special facilities for investigations in the fields of ore dressing, metallurgy and metallography.

Research Work: Testing of house-heating boilers (Journal A.S.M.E., Nov. 1916); commercial sampling and analysis of producer gas (Journal A.S.M.E., Dec. 1916); hardness tests on brass[1]; shearing strength of heat-treated steels; power losses in pneumatic tires (Bulletin S.A.E., Feb. 1917); grinding brass ashes in the conical ball mill (N. Y. Meeting, A.I.M.E., Feb. 1916); tests on the Hardinge conical mill (St. Louis Meeting, A.I.M.E., Oct. 1917); comparison between electrolytic and two varieties of arsenical Lake copper with respect to strength and ductility in cold-worked and annealed tests (Trans. A.I.M.E., 1916); growth of grain and diffusional characteristics on annealing bronze containing from 4 to 8 per cent tin (International Ztsch. für Metallographie, Oct. 1916); tests with various aggregates and sands; survey of sands in the vicinity of New Haven, Conn.

Industrial Research: Some investigations were conducted under a coöperative agreement with certain manufacturers. A similar arrangement is described by Professor Mathewson in his paper Coöperation with Metal Industries in Metallographic Work (Am. Inst. of Metals, 1916). As it may be of interest to manufacturers and other engineering schools, a brief outline of it is as follows:

A graduate student whose undergraduate work in this or other universities shows promise of ability to handle research work, is chosen by conference between the company and instructor involved. The aim of the company in the agreement then entered into is to obtain the solution of one or more of the technical problems with which it may be confronted, or, at the end of one or two years, to obtain as an employee a man especially trained in its work. As a means to accomplish one or both of these ends, the company furnishes the machine, apparatus, or material to be tested and pays the student during his graduate work a small salary, usually just sufficient to cover his living expenses, tuition and fees. The aim of the student is special training along a line in which he is particularly interested, the attainment of his advanced degree, and the chance to show to his future employer ability to handle such problems as may be presented to him. In return for the financial aid which he receives he agrees to devote at least half of his working time to the special problem submitted by his company. The other half is devoted to study of the collateral subjects required by the department for the granting of the degree which the student seeks. The student further agrees to enter the employ of the company in question at a wage not greater than that paid in like positions to recent graduates not specially trained and to remain with his employer at such wage for at least 1 year. If the student is to obtain a degree, the special work forming the basis of his investigation must be such as will involve real research and not mere routine manipulation. The subject is chosen by conference between the three parties to the agreement. The work is carried on under the direct supervision of the instructor involved. The school furnishes the general laboratory and library equipment essential to the pursuit of any extended investigation. In return it is expected that the results of the investigation shall be, in part at least, available for publication, if they are deemed of interest to the profession.

TULANE UNIVERSITY OF LOUISIANA

Experimental Work: The College of Technology has well-equipped laboratories. Investigations have been made of

[1] *American Machinist*, May 31, 1917.

pumping plant equipment under the auspices of the U. S. Department of Agriculture, and results have been reported from time to time in the bulletins of that department and in papers before the Society. Commercial tests of metals, woods and cements are frequently made. Other work touches on heat treatment of steel, reported in the *Journal of the Iron and Steel Institute*; physical tests of bricks manufactured in the States of Louisiana, Mississippi and Alabama, published in the *Transactions of the American Society for Testing Materials*; and drainage-pumping plants.

Department of Industrial Chemistry: Researches are made on local manufacturing problems, and it is endeavored to meet the peculiar demands of the locality in this respect.

West Virginia University

Equipment: Machine, woodworking, forge, sheet-metal and pipe shops and foundry.

Steam Laboratory: High-pressure boilers, separately fired superheater, simple and compound engines, steam turbine and condensers of different types; apparatus for testing separators, drop in line pressure, flow of steam, testing indicators, gages, etc.

Testing Material Laboratory: Testing machines ranging from 20,000 to 400,000 lb.; complete equipment for testing highway materials, cement and concrete; Brinell and Shore hardness-testing equipment.

Hydraulic Laboratory: Not extensive but well adapted to instruction work and for a limited amount of research work. Well equipped for measuring flow of streams.

Mining Laboratory: Well equipped for first-aid and rescue work, coal calorimetry and coal analysis; analysis of mine air, etc.; furnace work, mining machinery.

Oil and Gas Laboratory: Fitted up especially for testing lubricating oils and petroleum and for the extraction of gasoline from dry natural and casing-head gas.

Electrical Laboratory: Especially well equipped with dynamo-electric machinery of various types, transformers, rectifiers, condensers, high-tension apparatus and electrical instruments, electric-railway equipment.

Research Work: Combustion of natural gas under boilers and the heating value of natural gas; tests on West Virginia building brick in coöperation with the American Society for Testing Materials; drop in pressure in pipe lines, using differential manometers; correct form and location of sampling tubes for steam-calorimeter work; effect of superheat and change of vacuum on the economy of steam turbines; effect of varying percentages of carbon on the hardness of steels; flow of steam in pipes; distribution of concentrated loads on concrete slabs; crown thickness for concrete arches; study of slag concrete; curves for run-off of streams in Monongahela Valley; standardization of bridges, and culverts for State Road Bureau; study of the distortion of the field of a salient-pole alternator at various power factors; effect of inertia on the performance of a phase converter; effect of orienting the molecules of a gas on the opacity of the gas to Roentgen rays.

The Mining Engineering Department is the official Bureau of Research for the State Department of Mines, and does all the analyses of mine air, etc. The State Road Bureau also uses the laboratories.

Curriculum: Chemical engineering has been added and the course in oil and gas engineering has been enlarged. The plan of continuous sessions will be adopted, enabling those who are physically fit to graduate earlier. By this arrangement the present junior class may graduate by December 15.

News of Other Societies

Institution of Mechanical Engineers

The annual meeting of the Institution was held on Friday evening, April 20, 1917. The President, Michael Longridge, gave the address.

The war had taught us many things, he said, but none more clearly than the importance of our engineering industry. Upon this industry we depended for victory today and for security and prosperity tomorrow.

The mechanical engineer was in no small measure responsible for the transformation of the industrial life of England, and he must also be held responsible for the maintenance and efficiency of the workshop on which the feeding of the people and the defense of the people against their enemies now depended. He became and he remained a trustee for the British Empire.

In the view of the speaker the British engineers had not fully done their duty. As an example, he quoted the story of the engine-building trade of Lancashire. There was a time when Lancashire's supremacy in this branch of engineering was beyond dispute. But when the speaker went to the Paris Exhibition in 1900, he found that in elegance of form, in completeness of finish, in careful arrangement of details, the engines exhibited by some of the continental countries excelled the British stationary engine. It was, however, only through the repeated loss of orders that much later British engineers were forced to recognize the esteem in which continental products were held by customers. Later still the time came when complete steam engines built abroad were brought to England, erected and set to work by foreign workmen, even in the very home of British steam-engine manufacture, in Lancashire itself.

Some of the causes of the relative retrogression of British mechanical engineering, Mr. Longridge said, were beyond the control of engineers. Others they could remove in part or altogether. And of these he named inefficient technical education, lack of trade organization, and the policy of the trade unions. (Abstracted through *The Engineer*, vol. 123, no. 3200, April 27, 1917, pp. 371-374. *g*)

Canadian Society of Civil Engineers

At a luncheon of the Ottawa Branch of the Canadian Society of Civil Engineers on April 26, 1917, Colonel David Carnegie, Ordnance Advisor to the Imperial Munitions Board, delivered an address on the manufacture of munitions in Canada and the permanent assets to Canadian industry resulting therefrom.

In September 1914, said Colonel Carnegie, when General Sir Sam Hughes undertook the first order for shrapnel shells, Canada's capacity to produce shells amounted to 340 18-Pr. shrapnel shells per week. These were made at the Dominion Arsenal, Quebec. The capacity of Canadian factories today approximates 400,000 18-Pr. shrapnel complete rounds per week, including cartridge cases, primers, fuses and propellants. In addition to this amazing output there is a weekly capacity in Canada for nearly 400,000 high-explosive shells, ranging in sizes from 18-Pr. to 9.2 in., making an approximate total weekly output of 800,000 shells. This large output, along with other supplies made independently, requires each week about:

25,000 tons of steel	200 tons of antimony
2,500 tons of brass	150 tons of resin
750 tons of copper	500 tons of cordite

250 tons of zinc	500 tons of trinitrotoluol
1,500 tons of lead	300 tons of nitrocellulose powder.
Several tons of ferromolybdenum.	

Over 300,000 boxes are required for these shipments per week, and about 3¼ million lineal feet of board are used in making these boxes.

The weekly value of these products can only be understood by people who have learned to think in millions.

The total value of orders for munitions placed in Canada approaches eight hundred million dollars, and the value of the munitions shipped is close upon five hundred million dollars.

When the first order for 200,000 empty shrapnel shells was undertaken no one had any idea of the magnitude of the work, the foundation of which was then laid. That order, which required over six months to complete, represented eleven years' work at the rate of output of the Dominion Arsenal. The present weekly output of 400,000 18-Pr. shrapnel shells from Canadian factories is equal to twenty-two years' output from the Dominion Arsenal.

The uncertainty of securing material for the first order, of the right quality and in sufficient quantity, together with the difficulty in obtaining machinery and skilled labor to produce shells which would pass inspection and gun proof, made even the most courageous manufacturer hesitate to undertake the work without having the assurance of the Canadian Government that they would bear any financial loss incurred in the venture.

Instead of placing orders for the complete shells with each manufacturer, an arrangement was made whereby manufacturers whose domestic trade most nearly approached that required in producing the component parts of the shells were asked to undertake the work. Such parts, when finally inspected, were assembled and finished at the works of other manufacturers, who had to install machinery and plant for the purpose. The manufacturers were therefore not called upon to carry the responsibility for the purchase and inspection of any of the materials used in the shells.

They were also supplied with a complete set of inspection gages to guide them in making or obtaining manufacturing gages and in the standard of finish required by the Government inspectors.

While the manufacturers were relieved of these responsibilities, the cost of production was reduced and the quality of output improved by purchasing the materials through one agency instead of many, and by standardizing the inspection of work in supplying the gages to all makers.

All manufacturers were paid the same price for the same work. No competition was admitted among them, except the rivalry to excel each other in making the largest output that would pass Government inspection. This policy united the manufacturers without restricting inventive skill, ingenuity of design, and new methods of individual works management. It promoted a spirit of comradeship among them and an exchange of visits to their works. Freely were new ideas for cheapening and improving the quality of production used by all.

One could hardly mention this subject without being reminded of the almost insuperable difficulties which were presented in the early days of the war in obtaining gages for munitions. Canadians could never thank the United States manufacturers sufficiently for what they did in coming to their aid at that time. The special skill in making gages to the limits of accuracy required could not then be found in Canada. Today there were at least twenty factories producing gages in Canada, and while they were not independent of help from the States, some idea of the magnitude of the work could be understood from the monthly bill, which amounted to over $150,000 for new gages.

During the month of March about 10,000 new gages and checks were imported, the usual accuracy called for on a gage being 0.0003 in., and for a check 0.0001 in. An army of over 5000 examiners was engaged upon inspection under the direction of Colonel Edwards and his staff of officers.

The Engineers' Club of Brooklyn

THE Engineers' Club of Brooklyn was addressed at its meeting of April 26 by C. E. Drayer, Secretary of the Cleveland Engineering Society, on coöperation between Engineering Societies and the Newspapers to Promote Intelligent Public Opinion. Successful methods of close coöperation with newspapers were described in detail, as developed during a period of five years or more in the Cleveland Engineering Society.

News arose, said Mr. Drayer, from happenings that people wanted to hear about. It was evident that engineering topics which could not measure up to this standard could not compel space in the papers. On the other hand, if the society was doing things which would interest the readers of the papers, the editor could not for long keep accounts of such activities out of his paper and hold his job. But the inferred premise was wrong that editors did not welcome engineering news. They were eager for it if the right kind was supplied. At once the suggestion arose that the best way to learn how to supply copy was to get familiar with the standards of news measurement of the successful editor. The methods found successful in Cleveland would apply equally well anywhere, for people would be found to be people—with very slight variations—everywhere.

Publicity, which had received so much emphasis of late, was a means only, not an end. The end was service to the community first, to the engineering profession second, with mutual profit. When the public learned that the engineer was honest and efficient, capable of administering its affairs better than now done, it would make short work of the old-time politician. The present widespread call for the city-manager form of government over the country was but a demand for capable government. It was a call for engineers, but not for the kind that were content with technical matters, but for men having technical training plus the determination of the lawyer to be a leader in the community and the mixing ability of the politician.

The speaker told of the activities of the Cleveland Engineering Society in building-code legislation, paving supervision and water supply for the good of Cleveland and predicted that the next mayor would be an engineer. He said there would be no dearth of engineering news and that the space in the newspapers would be freely open to engineers when they woke up to their opportunity and took what was awaiting the taking.

Using the Cleveland Engineering Society as an illustration of what could be done when engineers were united in a community, Mr. Drayer urged unity and federation of engineers of the United States after the manner of the Chamber of Commerce of the United States, and noted the wonderful influence of the American Institute of Architects, which, with a membership of but 1200, had nevertheless left its imprint on the nation more deeply than all the engineering societies, because it had been properly organized. He arraigned the recently formed

Engineering Council as missing its opportunity in that it was undemocratic, made no provision for fellowship and did not find its strength for directing legislation where men voted.

Shipping Pig Iron (Not Pigs) in Refrigerator Cars

"So short has been the supply of cars in the South that iron has been shipped to navy yards in refrigerator cars. These came loaded with iced beef, but were seized by the Government as the only available equipment and loaded out with pig iron."

This statement from a report of the iron market, issued by the Matthew Addy Company of Cincinnati, clearly indicates the serious shortage of rolling stock, when even the National Government must adopt such heroic measures as using refrigerator cars for the handling of pig iron.

In discussing the iron market in connection with this rolling-stock situation, the Matthew Addy Company's report says:

"It is apparent that Government needs and Government's right of eminent domain, so to speak, are going to have a profound effect on the iron market. They have introduced a new element into the situation and have made conditions more strenuous. In some districts Uncle Sam is requisitioning cars by the hundreds and ordering steel by the million tons; everywhere it is evident that the Government must be served first and that private consumers must sit at the second table. There is no objection to this. All realize that Uncle Sam is and must be paramount. But that does not change the fact that the private consumer is discommoded, and that in many cases he finds his regular source of supply abruptly cut off. And the thing has just begun. What the end may be is a mere matter of conjecture.

"This week there has been a great increase in inquiry. Demand for iron knows no limits. Part of this demand comes from the fact that iron that was bought has not been shipped, and if consumers cannot get what they have under contract, they must get it elsewhere. As an example of this, one of the large Birmingham producers has in 60 days piled to exceed 45,000 tons of iron on its yards simply because it is impossible to get cars in which to ship, as the Government has requisitioned 50,000 cars for coal and rails. And all the time consumers are clamoring for this very iron. So short has been the supply of cars in the South that iron has been shipped to navy yards in refrigerator cars. These came loaded with iced beef, but were seized by the Government as the only equipment available and loaded out with pig iron. It is things like these that bring to the mind the forcible realization of the fact that the railroads have fallen down in this great crisis. But the people who starved the railroads are the only ones to blame." (*Manufacturers Record*, vol. 71, no. 21, May 24, 1917, p. 47)

The *American Machinist* of May 31, 1917, mentions the receipt of a 600-page catalogue of the Lyons Fair which was held at Lyons, France, from March 18 to April 1 of this year. Considering the conditions under which this fair has been carried out, the *American Machinist* calls the exhibit nothing if not miraculous. Besides a comprehensive representation on a large scale that drew exhibits from practically all the industries of France and her colonies, many allied and neutral countries were represented. The machine tool section of the catalogue covers 14 pages, and among the representatives of the industry one notices the names of 15 American builders of machine tools.

This Month's Abstracts

At the present time, when the United States Government has under consideration the expenditure of hundreds of millions of dollars on aviation, the data on propellers abstracted from two papers by J. Lawrence Hodgson are of particular interest.

The description of a British continuous enameling and stoving machine is reported from an article in (London) *Engineering*.

L. R. Brown, in the *Engineering News-Record*, publishes data of some tests of sand in concrete showing the influence of the duration of tests on the results secured.

The abstract of a paper on the influence of temperature on the bending resistance of mild-steel and copper wires, originally published in the *Zeitschrift des Vereines deutscher Ingenieure*, is here reprinted from *Science Abstracts*. This is because German journals do not reach this country, but appear to be available in London.

W. K. Shepard, in an article on the hardness tests of brass, shows that the plotted relation between the scleroscope hardness number and the ultimate tensile strength for brass is parabolic (straight line for steel). On the other hand, no constant relation was found between the scleroscope and the Brinell hardness numbers for brass.

Attention is called to the article on the performance of lubricating-oil coolers by M. C. Stuart, Mem.Am.Soc.M.E. This article covers the relation between performance and the weight, volume and amount of cooling surface in various types of coolers.

The use of oscillographs for the study of internal-combustion engines, especially in regard to phenomena of ignition, described in the section Measuring Apparatus, deserves particular attention, as this instrument has proved to be an extremely valuable adjunct in the study of electrical machinery.

The Laws of Elastico-Viscous Fluids, by Prof. A. A. Michelson, will be found, in abstract, in the section Mechanics. The writer makes an attempt to formulate the behavior of substances under stress by the simplest expressions which have been found to satisfy all the essential requirements, and states that the behavior of any solid under stress may be considered as the resultant of four elements constituting the laws of elastico-viscous flow.

From papers and discussions before the recent Convention of the International Railway Fuel Association have been taken two abstracts on locomotive feedwater heating: one more or less theoretical, and the other of mainly an experimental character.

The still largely uncertain subject of circulation in flooded systems has been investigated by means of glass models, as described in an article abstracted from the May *A. S. R. E. Journal*.

The section Steam Engineering in this issue contains several abstracts of more than usual interest: Recent Installations of Large Turbo-Generators, a paper read by Richard H. Rice before the American Iron and Steel Institute, presents many data on the most modern practice, with estimates of costs in heat units and money. Another paper, by John A. Stevens, read before the Boston meeting of the National Association of Cotton Manufacturers, also gives data on turbine practice, and in addition presents a highly interesting description of a new type of boiler (Stevens-Pratt), so large that the length of the tubing, both in the boiler and the superheater, is measured in miles.

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

Aeronautics

Tests on Model Propellers

Abstracts of two papers presented to the Institution of Automobile Engineers: the first entitled, The Characteristic Curves of a Propeller; and the second, An Experimental Investigation as to the Relation Between the Thrust Ratio of Lifting Propellers and the Number, Arrangement, Shape, Section and Pitch of Their Blades, both by J. Lawrence Hodgson.

The Characteristic Curves of a Propeller. The investigation was undertaken with a view to obtaining a general idea as to the performance of a propeller when it was moved at various speeds forward and backward along its axis of rotation, and to express this information in some simple way so that the approximate performance of any similar propeller working in a fluid medium of any given density might be readily deduced.

If, when comparing the performance of similar propellers working at the same slip ratio, the resistances due to skin friction and viscosity are assumed to follow the velocity-square law and change of density in the neighborhood of the propeller is neglected, there are six main features to be considered. These are, thrust in lb., T; revolutions per minute, N; torque in lb-in., q; speed of advance in ft. per sec., V; density of fluid in which propeller rotates in lb. per cu. ft., W; diameter of propeller in inches, D.

For given values of W and D, it is not possible to predict accurately by any simple theory the manner in which T, N and q will vary for different values of V. This may, however, be determined experimentally and expressed by means of curves. The experimental values may be obtained in three ways: viz., with T constant, or with N constant, or with q constant. In the experiments described in this paper the first way has been adopted.

If, instead of plotting the experimental values of N and q to obtain various speeds of advance for given values of W and V when T is constant, we plot non-dimensional coefficients which connect these values with two or more of the other variables, general curves are obtained from which the performance of any similar propeller under any conditions may be deduced. Such curves No. 1 and No. 2, Fig. 1, may be termed the characteristic curves of the propeller, since they entirely define its performance under any given conditions.

If the units in which the six variables are measured are consistent among themselves, these characteristic curves can be used without recalculation, but the curves in the present paper cannot be so used.

The propeller used for the present tests was 6.25 in. in diameter and had a pitch of approximately 6 in. Its blades were constructed of soft brass and attached to a central boss.

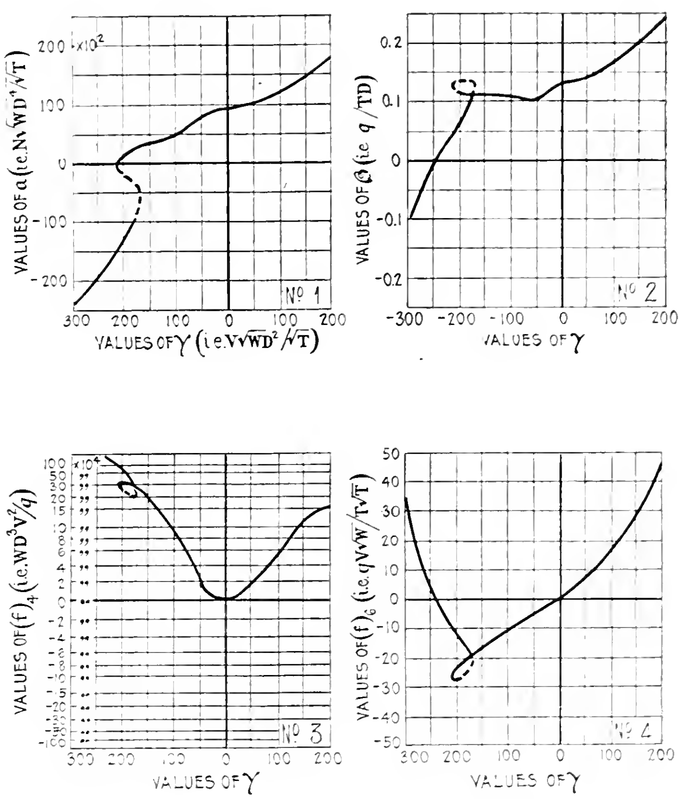


Fig. 1 Characteristic Curves of Propellers

All the tests were carried out in water, and the paper describes in detail the experimental apparatus and method of carrying out the tests.

A series of comparative tests taken in the same bell mouth with similar propellers 3 in. and 6.25 in. in diameter, respectively, showed that at comparatively small positive and negative speeds of advance the proximity of the walls of the bell mouth produced practically no effect.

The experimental results reduced to 1 lb. thrust for the 6.25-

in. diameter propeller are plotted in curves reproduced in the original article.

The following special points of interest are brought out in these curves. It was found that when the speed of advance is negative, it is possible to obtain the same thrust at different torques and with the propeller rotating at widely different speeds. Further, it appears that the experimental mean pitch as determined from the lines of zero thrust (at zero thrust the experimental mean pitch multiplied by the revolutions equals the speed of advance) is greater when the fluid impinges upon the leading edge of the propeller than it is when the propeller is reversed and the fluid impinges upon the trailing edge.

These tests have indicated how N and q are related to V when V, W and D are constant. Under certain assumptions the variations of N, q and V with T, W and D follow quite simple laws for points on the curves for which the ratio V/DN is constant.

Coefficients α, β, γ, which connect N, q and V with the expressions involving T, W and D, are determined as follows:

Since $T \propto N^2WD^4$ for points for which the ratio V/DN is constant, we may write

$$N = \alpha\sqrt{\frac{T}{WD^4}}$$

whence

$$\alpha = N\sqrt{\frac{WD^4}{T}} \quad \ldots\ldots\ldots\ldots [1]$$

Also, since

$$q \propto N^2WD^5, \text{ or}$$

$$\propto \alpha^2 \frac{T}{WD^4} WD^5 \text{ by [1],}$$

we may write

$$q = \beta TD$$

whence

$$\beta = \frac{q}{TD} \quad \ldots\ldots\ldots\ldots [2]$$

Further, since for the points considered the ratio V/DN is to be constant, we may write

$$V \propto DN$$

$$\propto D\alpha\sqrt{\frac{T}{WD^4}} \text{ by [1]}$$

$$V = \gamma\sqrt{\frac{T}{WD^2}}$$

whence

$$\gamma = V\sqrt{\frac{WD^2}{T}} \quad \ldots\ldots\ldots\ldots [3]$$

In the foregoing, α, β, and γ are numerical coefficients which may be calculated from the experimental results.

Curves connecting α and γ and β and γ are plotted at (1), (2), Fig. 1.

These curves, if used in conjunction with equations [1], [2], and [3], enable us, if we know T, W and D and one of the variables N, q and V, to find either of the other two.

The paper proceeds to the discussion of certain problems which may arise in calculating propellers geometrically similar to the model used.

For the solution of such, in similar cases, the writer suggests the derivation of a number of additional equations and curves from the three equations and the two curves referred to above. Such equations are immediately derived by him and collected in a table in the original article.

Among other things, an equation is given for the calculation of the thrusts of the ideal stationary propeller. Further, data are presented showing how the value of the "thrust ratio" t, which is defined as the ratio of the actual thrust to the theoretical thrust, is affected by the number of blades, the blade section, the developed blade outline, the developed edge elevation of the blade, the designed pitch, and the angle between the chord and the aerofoil section and the plane of rotation of the propeller, this latter under the assumption that the pressure face of the blade is perfectly flat.

This is done in the second paper, which represents an experimental investigation as to the relation between the thrust ratio of lifting screws and the number, arrangement, shape and section of their blades. The paper is suitable for abstracting only in parts.

The writer found from an examination of the stream-line flow through a stationary propeller by means of smoke filaments that the minimum diameter of the slip stream is about 0.6 of the blade diameter. Further, the smoke filaments show that in the case of a propeller of the usual pitch ratio having thin blades of good aerofoil section, the rotation of the fluid set up is small. From this the author proceeds to establish equations for the calculation of the thrust of a propeller and the determination of factors affecting the value of the thrust ratio. From a large number of experiments it was found, among other things, that the value of thrust ratio is only very slightly increased by using blades of helical form.

Also an unexpectedly small diminution was found in the value of the thrust ratio consequent upon the rounding off of the leading edge of the aerofoil section. On the other hand, a great reduction was found consequent upon cutting down the blade outline and modifying the edge elevation. Likewise a great reduction was produced by adding round struts and wires to the propeller, but a quite high value of thrust ratio was found possible in the case of propellers strengthened by struts, provided that these are made of streamline form.

The broad conclusions from these tests, which were carried out with the object of obtaining data for the design of lifting propellers of large size, would seem to be that there is little advantage (except reduction of vibration) to be gained by constructing such propellers with more than two blades, or by making the blades helical instead of flat (if the blades are made flat, the longitudinal spars are much simpler). It would also appear to be quite practicable to use blades of thin aerofoil section stiffened up by exposed struts and wires of streamlike form. It is also advantageous to thin down the blades at the tip and along the trailing edge. So far as the experiments show, there seems to be but little to be gained by departing from blades of rectangular blade outline.

Higher values of τ might have been obtained by putting the "planes" considerably farther apart. But this would have been inadmissible in practice for constructional reasons.

A reference to the streamline diagram will show that it is preferable to place the motor or any other necessary obstruction to the flow on the intake side of the lifting screw so as to avoid undue loss of energy by friction in the high-velocity slip stream.

This point seems to be well understood by those who design electric fans and screw-propelled ships. It is, however, of far less importance in the case of an aeroplane propeller, owing to the high velocity of the aeroplane.

The same diagram also shows how necessary it is to "shroud" a circulating fan, such as a radiator fan, which is

required to produce a high velocity on the intake side. (*The Automobile Engineer*, vol. 7, no. 101, April 1917, pp. 90-95, 16 figs., *etA*)

Enameling

Continuous Enameling and Stoving Machine for Small Parts

Description of a machine manufactured in England for enameling and stoving a great variety of parts of different shapes and sizes by continuous mechanically effected rotation. It is stated that it has an output up to 2000 parts per hour, with the attendance of only two unskilled operators.

The machine consists of two distinct units: one, the painting or enameling machine, and the other, the stoving machine. The painting machine consists of a table on which is mounted a vessel in the form of a tube or tunnel through which the articles to be painted are passed at a uniform speed and at a uniform distance from each other by means of an endless chain and wheels driven by a small electric motor. Each part to be painted is hung on a specially prepared hook, and these hooks are so made that they insure the various parts being kept at an equal distance from each other. The speed at which these parts pass through the tunnel can be up to 2000 per hour, and the distance of each part from the other can be varied to suit the requirements. On each side of the tunnel are placed two or more pneumatic paint-spraying machines which operate through coned openings in the sides of the tunnel and are so disposed as to insure the paint from the sprays reaching all the surfaces of the article being painted during the passage through the tunnel. After passing through the painting unit each article is disposed automatically by the machine on a small rod which forms a connecting link between the two units of the apparatus.

The continuous stoving machine consists of a rectangular chamber about 16 ft. long by 4 ft. wide, heated by suitable gas jets and fitted with a sliding door at the rear end. Two continuous chains with suitable sprockets are provided, one on each side of the machine, and operated by a handle so arranged that at each revolution of the handle the chain travels longitudinally inside of the stove a distance of about $4\frac{1}{2}$ in. These chains are provided to carry rods on which are suspended the parts which have been painted. Each rod travels through the stove at a rate equal to that of the number of revolutions of the handle. The result is that by the time the parts on any one rod have traveled through the whole length of the stove they will have been subjected to the heating for a definite period and the stoving operation completed. (*Engineering*, vol. 103, no. 2678, April 27, 1917, pp. 410-411, 1 fig., *d*)

Engineering Materials

Long and Short Sand Tests, L. R. Brown

The writer mentions a case where the results of a 7-day test of sand were so unfavorable that it was rejected. A 28-day test also showed the quality of the sand to be poor. The sand was, however, next tested with a different brand of cement and quite favorably passed the test at the end of half a year.

The writer believes, therefore, that probably the values of combinations of lake sand and cement found in the 7-day and 28-day tests are influenced by properties in the sand that hasten or retard the setting of the cement. Thus, a comparatively high value resulting from a mixture of sand and cement may be due to chemical action produced by the combination of certain chemicals in each that hasten the setting of the mortar, rather than deliver a neutralization of the injurious substances in the sand by the chemicals in the cement.

From his tests the writer comes to the following conclusions:

1 Nearly all well-graded sand has proved reliable on a 6-month test.

2 The reason for the low values obtained in the 7-day and 28-day tests is due to a delay in setting because of chemical properties in the sand or cement.

3 While changing the brand of cement used with a given sand may give higher values for 7 days and 28 days, the 6-month results may be lower.

4 The addition of small quantities of alkali to the mortar probably has only the effect of hastening the hardening of the mortar. (*Engineering News-Record*, vol. 78, no. 10, June 7, 1917, pp. 504-505, *e*)

Influence of Temperature on the Bending Resistance of Mild-Steel and Copper Wires, Lautz

An apparatus has been designed in which it is possible to effect the alternate bending of wires through an angle of 180 deg. while the specimen is heated at temperatures up to 320 deg. cent. in an oil bath. The results of a large number of tests show that the resistance of iron wires to fracture by alternate bending remains fairly constant up to 120 deg. cent. Between 120 deg. and 220 deg. the resistance increases rapidly, and above the latter temperature falls very abruptly. The maximum values are about double those observed at ordinary temperatures. In annealed wires the maximum is very pronounced, but it is nothing like so sharp in unannealed wires; further, it occurs at about 10 or 20 deg. higher in the unannealed samples. Contrary to expectations, copper broke quicker than iron at ordinary temperatures; the number of alternations rose continuously with the temperature. Bending around a sharp edge gives more reliable results than bending around a radius. The work is to be continued so as to determine the effect of variation in composition, and so on. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 60, pp. 785-788, September 23, 1916, through *Science Abstracts, Section A—Physics*, vol. 20, pt. 4, p. 122)

Experiments with Cold-Drawn and Annealed Ingot Iron, O. Bauer

A series of tests was made on cold-drawn and annealed ingot iron. The physical tests consisted of the determination of Brinell hardness, resistance to shock and tensile strength. The chemical examination consisted of solubility tests in 1 per cent H_2SO_4 for 70 hours and rust tests in 1 per cent NaCl for 30 days. It was shown that the solubility in acid gave better results in ascertaining the approximate annealing temperature than the Brinell hardness, and that as the annealing temperature rose, the solubility in H_2SO_4 diminished. The rust tests did not give satisfactory results, and there appears to be no distinct relation between the temperature of annealing and the rusting tendency of the Fe. (*Mitt. kgl. Materialprüfungsamt*, 33, 395-407; *Chem. Zentr.* 1916, I, 1281, through *Chemical Abstracts*, vol. 11, no. 11, June 10, 1917, p. 1625)

The Hardness Tests of Brass, William Kent Shepard

Data of an investigation made by the Sheffield Scientific School to determine the relation between the ultimate tensile

strength of brass and the hardness number as found by the Brinell and scleroscope tests.

Investigations of a nature similar to the present have been made on various styles, and in each case an appropriate straight line relation was found to exist between the ultimate tensile strength and the hardness number, whether Brinell or scleroscope.

In this test annealed brass and brass that had been cold rolled with reductions in thickness from 1 to 15 per cent of the original was used. It was all one grade, about 66 per cent copper and 34 per cent zinc. The data are presented in the form of tables and curves. It was found that the relation between the scleroscope hardness number and the ultimate tensile strength is parabolic for brass, and not a straight-line relation as in the case of steel. Likewise a parabolic relation was found to exist between the Brinell hardness number when determined by each different load and the ultimate tensile strength of brass.

The curves are tabulated to show also that there is no constant relation between the scleroscope and the Brinell hardness numbers for brass. In the curves the points are seen to be widely distributed along a general straight-line direction. (*American Machinist*, vol. 46, no. 22, May 31, 1917, pp. 935-937, 7 figs., *d*)

Hydraulic Engineering

Low-Head Power Development at Prairie Du Sac, H. W. Young

Description of a hydroelectric plant of the Wisconsin River Power Company, of 15,500 kw. capacity, representing recent practice in design of low-head waterpower development.

The construction and efficient operation of plants of the type of the one described here have been made possible through the progress of hydroelectric engineering in the last few years. Until quite recently, the difference in the mean low-water flow and the flood flow of a river has not been given due consideration. As a result, lack of sufficient spillways and adequate machinery to operate properly the flood outlets has endangered, to a great extent, all low-head waterpower developments where these conditions of flow existed. This feature had to be particularly provided for in the Prairie du Sac development, where the mean low-water flow is 5000 sec.-ft. and the high flood flow has reached 26,000 sec.-ft. This big difference has been taken care of by the installation of 41 Tainter gates, 14 ft. high and 20 ft. wide, placed on top of the spillway section of the dam. This permits control of all stages of floods and has a very important bearing on the present successful operation of the plant. These gates are all electrically operated.

The present normal head utilized is 28 ft., maintained the year around, as nearly as possible, by means of the control gates. In time of flood water, however, this is somewhat decreased by the backing up of the water in the tailrace, the loss of head from this cause being sometimes as high as 8 or 9 ft. Lubrication

The Performance of Lubricating-Oil Coolers, M. C. Stuart (Mem.Am.Soc.M.E.)

A paper presenting the main data of tests carried out at the U. S. Naval Engineering Experiment Station at Annapolis. This paper covers the relation between performance and the weight, volume and amount of cooling surface in various types of coolers.

With cooler installed and a certain oil selected for use, the variables for the test are limited to quantities of oil and cooling water circulated, and oil and water temperatures. Hence the test is divided into two parts: first, runs in which the rates of flow of oil and water are maintained constant and the temperatures of the inlet oil and water varied; and second, runs in which the inlet temperatures are maintained constant and the rates of flow of oil and water varied.

In the first division of the test runs are made with inlet water of varying temperature, say, 80 to 90 deg. fahr., and at each inlet water temperature runs are made with varying inlet oil temperatures, say, 120, 140, 160 and 180 deg. fahr. The resultant outlet temperatures of oil and water are plotted on what is termed a temperature diagram. Fig. 2 shows the relations between all the temperatures involved in the performance of the cooler at constant rates of flow of oil and water.

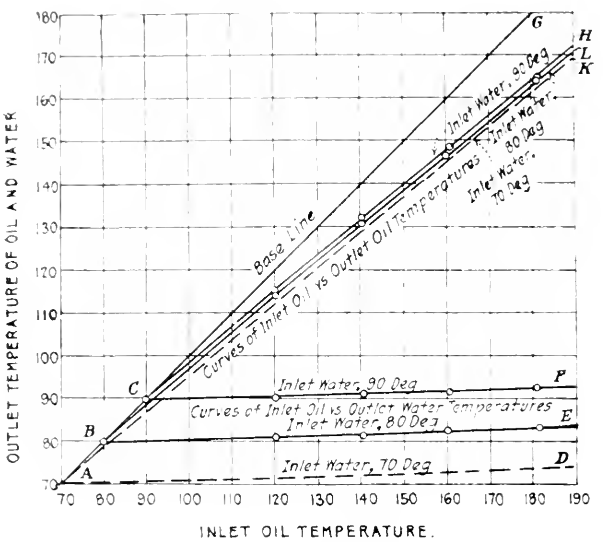

FIG. 2 TEMPERATURE DIAGRAM

This "temperature diagram" is a valuable aid in the analysis of the performance of oil coolers. As shown in Fig. 2, the abscissæ are inlet temperatures and the ordinates are outlet temperatures. A base line, or equal temperature line *AG*, is first drawn diagonally across the diagram. The values of inlet oil temperature versus outlet oil temperatures for the runs in which the inlet water temperatures were 90 deg., are plotted and line *CH* is drawn through the points. The intersection of this line with the base line at *C* is determined from the following consideration. Although the lowest inlet oil temperature was 120 deg., it is evident that if the inlet oil temperature should be reduced to the inlet water temperature, or, in this case 90 deg., the outlet oil temperature would equal the inlet oil temperature. In other words, the curve of inlet oil temperatures versus outlet oil temperature for a constant inlet water temperature intersects the base line at the temperature of the inlet water. In the same manner the curve *CF* of the inlet oil temperature versus outlet water temperature also intersects the base line at the inlet water temperature. The lines

BL and *BE* represent the results of runs made at inlet water temperature of 80 deg.

The important property of the temperature diagram is that the lines are straight, or very nearly straight, and the lines of a group are parallel. By means of this property curves may be constructed for other water temperatures than those

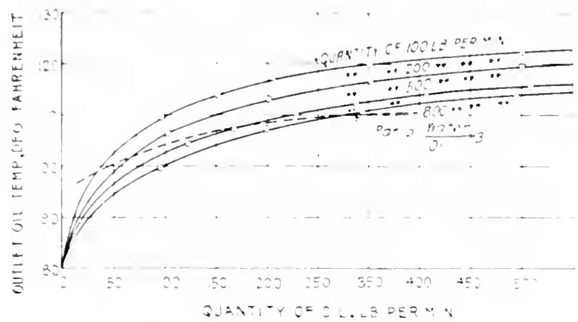

FIG. 3 QUANTITY DIAGRAM

covered in the test. Thus, in Fig. 2, the dotted lines *AK* and *AD* represent the outlet oil and outlet water temperatures, respectively, for an inlet water temperature of 70 deg.

The writer shows how such a diagram may be constructed from data of a single run. The temperature diagram may be

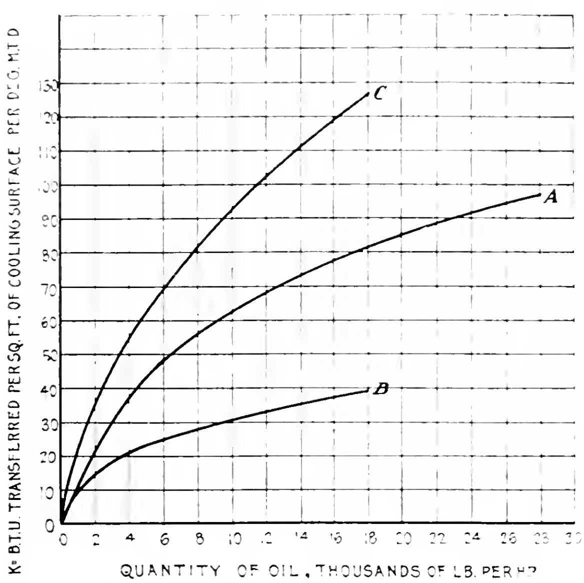

FIG. 5 HEAT-TRANSFER COEFFICIENTS OF THREE COOLERS

used to derive an analytic method of determining the relation between the various temperatures of the oil cooler. In fact, he establishes the following formula:

$$\frac{T_1 - T_o}{T_1 - t_1} = C$$

in which T_1 = inlet oil temperature; T_o = outlet oil temperature; and t_1 = inlet water temperature.

Data from a single run at given quantities of oil and water may be used to determine the value of flow. Then for any other conditions of inlet oil temperature and inlet water temperature the value of the oil temperature drop and outlet temperature may be found by substitution in the above equation.

The writer discusses next the problem of determining both inlet and outlet oil temperatures. The further use of the temperature diagram is in showing the effect of the placing of two or more coolers in series, or the effect of tube length.

The temperature diagram deals, however, only with variable temperatures, and gives no information regarding the effect of various rates of flow of oil or water. Hence, a second division of a test of an oil cooler becomes necessary with the temperatures of inlet oil and inlet water constant and rates of flow of oil and water variable. The results of such a group of runs are plotted in Fig. 3 and constitute what is termed a "quantity diagram." The curves of Fig. 3 are cross-plotted in Fig. 4, to coördinates of water quantity and outlet oil temperature with curves of equal oil quantities. The two figures taken together show the complete relation between oil temperature flow and rates of flow of oil and water.

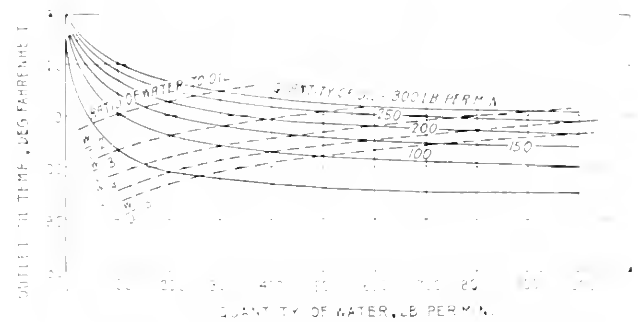

FIG. 4 QUANTITY DIAGRAM IN FIG. 3 CROSS-PLOTTED

The quantity diagram provides a basis for determining the capacity of an oil cooler and rating it. But to say that a cooler has a certain capacity and not state definitely the conditions under which this capacity is produced is very unsatisfactory. The rating of a cooler may be defined as that quantity of a particular kind of oil which will be given the desired temperature drop with certain inlet oil and inlet water temperature and a certain quantity of water, or a certain ratio of water to oil used.

This theoretical discussion is followed by data and discussion of the actual performance of three types of coolers so selected that their performances should be comparable. Cooler *A* is of plain tubes; cooler *B* of plain tubes fitted with retarders; and cooler *C* of special corrugated concentric tubes, with dissimilar oil and water arrangements. The writer considers the heat-transfer coefficient as a measure of the surface effi-

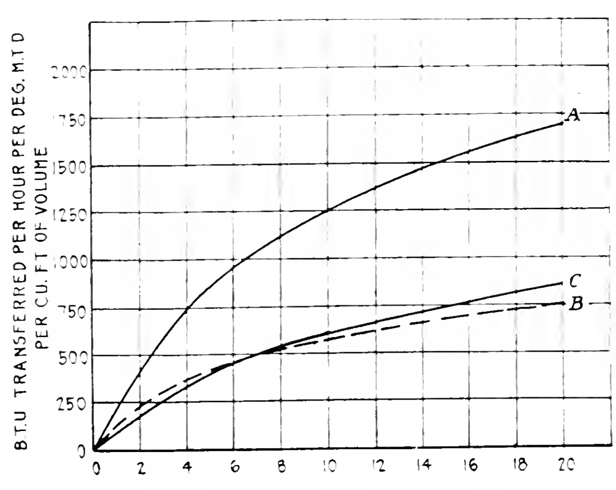

FIG. 6 VOLUME EFFICIENCIES OF THREE COOLERS

ciency of the cooler, but points out that the efficiency of the volume of the cooler is far more important than surface efficiency. A factor which places performance on a basis of volume of apparatus is B.t.u. transferred per hour, per degree mean temperature difference, per cubic foot of volume. From this point of view it is of interest to compare Fig. 5, which gives the heat transfer coefficients, with Fig. 6, giving the volume efficiencies of the same three coolers. Of particular interest is the relative position of the curves B and C to each other in the two figures.

Finally the friction drop in the oil is considered, and it is found among other things that the relative friction drops are in the same order as the relative heat-transfer factors. In this connection it is also noted that weights per square foot of surface are in the order of the heat-transfer factors.

Summing up the subject of relative performance and merit of various types of coolers, the writer states that that cooler is best which will produce a given temperature drop in a given quantity of oil with the least volume and weight and without excessive friction drop. (*Journal of the American Society of Naval Engineers*, vol. 29, no. 2, May 1917, pp. 300-318, 10 figs., *teA*)

NAVY LUBRICANTS AND LUBRICATION. Lieut.-Commander H. T. Winston, U. S. N.

The writer discusses the selection, testing and purchasing of lubricating oils for the Navy Department for various uses, such as lubricating oils for machinery, lubricants for cutting tools, greases, graphites, etc., and in an appendix gives the Navy specifications and tests for these materials.

Among other things the writer states that oils containing only 8 or 10 per cent of blown rape-seed, or other fixed oil, are not very satisfactory, especially at high speeds. The reasons for this are not entirely clear and the personal equation may be an important factor. Such oils do not form a heavy lather and seem to run off bearing surfaces easily, allowing the bearing to heat up. Possibly the mineral-oil contents used in these oils have too low viscosities and do not contain the emulsified constituents needed for sticking to the surface of the bearing. These oils also feed more rapidly than the heavier oils, unless the wicks are reduced in number, or the feed otherwise cut down. Hence, a man familiar only with the heavy oil is likely to let the oil box empty rapidly and the bearing run dry.

Straight mineral oils which form an emulsion with water and are exclusively a home product have been used with very good results in lieu of the compounded oil. This is shown by extensive tests on the torpedo boat *Bailey* at Annapolis, the battleship *Nebraska*, and other vessels. While the straight oil does not give a heavy lather, the bearings do not heat up; in fact, the machinery is cleaner and neater without a heavy lather.

The writer goes fully into the matter of classification of oils and the discussion of physical properties of straight mineral oils. As to the latter, he states that the important lubricating properties are viscosity, cold (or pour) point, emulsibility with water (cold or hot), and carbon actually deposited in an internal-combustion engine. Unimportant properties are carbon passing through the engine, gravity, fire point, flash point and frictional resistance.

Mixing similar *good* oils does no harm, and the resultant product shows no unexpected or abnormal properties.

As regards the so-called "worn-out" oils, the writer states that there is little evidence to show that a good oil wears out or loses any essential lubricating properties under ordinary circumstances. High heat will cause some light oils to become heavier, due to the distillation of a percentage of the original product, but the result is then simply a somewhat reduced amount of good oil with the increased viscosity. Interesting tests have been made on "used" lubricating oils, and a full description of such tests is expected to appear in the *Journal of the American Society of Naval Engineers*. Good oils used in forced-feed lubrication systems showed after about 1000 hours' use some oxidation, but the lubricating properties were not materially changed. The cold points were raised 10 to 20 deg. fahr. and there was an increase in the formation of organic acids and of resins. However, such harmful ingredients are easily removed by filtering the oil through animal charcoal, the filtered product being as good as, or, possibly better than, the original oil. (*The Journal of the American Society of Naval Engineers*, vol. 29, no. 2, pp. 239-261, *gd*)

Machine Shop

CALCULATING THE APPROACH OF MILLING CUTTERS, Francis J. G. Rueter

The distance between the initial and final point of contact with the work, considering the point on the periphery of the cutter, is called the approach. This distance is used in time-study estimating together with the length of the piece or cut to determine the time required by the machine to do the work. The result is called the machine time.

To calculate the approach by the ordinary mathematical method requires too much time. The writer has therefore deduced a simpler formula from which the approach can be calculated by means of a chart in the original article. The solution is also easily made with logarithmic cross-section paper and by a slide rule. (*American Machinist*, vol. 46, no. 22, May 31, 1917, pp. 928-930, 7 figs., *p*)

Measuring Apparatus

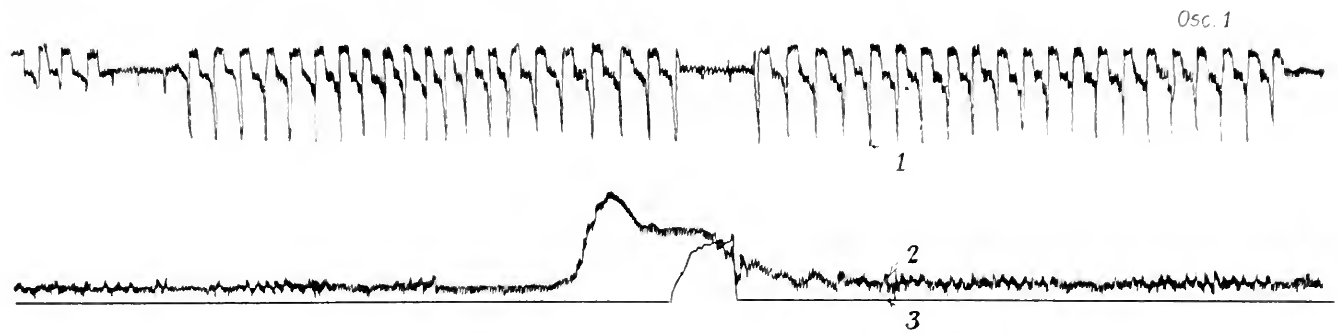
A NEW FORM OF PITOT TUBE, A. Hagenbach and K. Gégauff

Describes an exploration of the space surrounding a circular plate in a stream of air, the direction of the stream lines and the velocity and static pressure of the air being found by means of a new form of gage. This consists of a small tube of 1.6 mm. outside and 1 mm. inside diameter, closed at one end and pierced at the side with a small hole. The open end of the tube is connected with a pressure gage by means of an india-rubber tube. The closed tube is several centimeters long and is placed with the portion containing the opening at the point to be studied, the axis of the tube being perpendicular to the direction of the air stream. The tube is then rotated until the maximum pressure excess is obtained. This, by means of a pointer attached to the tube, gives the angle of the stream line. The tube is then rotated through 44 deg., first on one side of this direction and then on the other. The mean pressure at these points is the static air pressure, for it has been found by preliminary experiments that, for all air velocities, the null pressure is shown at an angle of 44 deg. (for the particular tube employed) from the direction of flow, while at 85 deg. the points of minimum (reduced) pressure are found. The results obtained in the case of air flowing at an average speed of about 6.5 m. per sec. past a normal circular plate are tabulated in full in the paper, and a map of isobars and stream lines is also given. (*Physikalische Zeitschrift*, vol. 18, pp. 21-30, January 15, 1917, through *Science Abstracts, Section A—Physics*, vol. 20, pt. 4, pp. 124-125)

THE USE OF OSCILLOGRAPHS FOR THE STUDY OF EXPLOSION ENGINES, M. Camillerapp

The writer indicates a method of investigating the part played by heat and the behavior of the spark in an explosion engine by means of the Blondel oscillograph.

In the course of a series of experiments made for the purpose of determining the part played by heat and the duration of the spark of the plug in the operation of an explosion motor, it proved to be impossible to use a manograph, because it was necessary to register simultaneously: *a*, the variations of pressure in the cylinder; *b*, the time between two explosions in the same cylinder with the view to determining the speed of the engine; and *c*, the current in the spark and its duration.



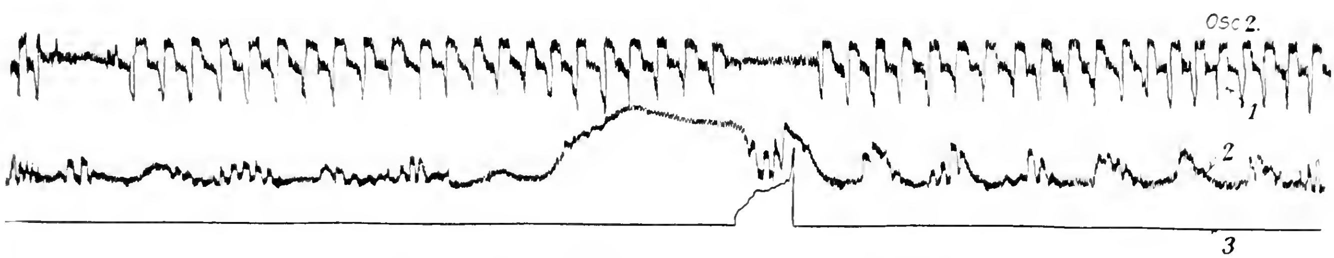


FIG. 7 (TOP) OSCILLOGRAM OBTAINED WITH THE SINGLE MICROPHONE

FIG. 8 (BOTTOM) OSCILLOGRAM OBTAINED WITH THE DOUBLE MICROPHONE

Curve 1 of the oscillograms in Figs. 7 and 8 represents the vibrations of a Lancelot electro- diapason giving 200 double vibrations; this gives the velocity of the photographic film of the decoiler of the oscillograph. This curve also gives the speed of the motor. To do this the current of the diapason passes through a rotary contactor located at the end of the motor shaft. This contactor short-circuits at each revolution with a resistance placed in series with the carrying circuit of the oscillograph. Hence each revolution of the engine is indicated by a fall in the amplitude of the curve of the diapason and the speed of the engine is measured by the oscillations registered between each revolution. The tests were carried out by a special laboratory-type oscillograph, and as quantitative results were not sought and it was only desired to obtain curves that would give an idea of the manner in which the ignition of the gas occurs, a special microphonic apparatus was employed.

Curve 2 shows pressures in the cylinder of the engine. It was obtained by means of a microphone held on the spark-plug frame in a manner illustrated in the original article.

Curve 3 gives the ignition current of the spark plug. A calibration of the oscillograph permits the determination of its volume in milliamperes; the return of the curve to 0 gives the duration of the arc between the terminals.

While the author makes no attempt to present the results obtained in his investigation, he indicates that, contrary to the view held by many engineers, ignition is not followed by a sudden explosion and the spark is not extinguished by the explosion, which he explains by the fact that after all no explosion occurs in the cylinder of the engine in the proper sense of this term; i. e., no sudden increase in the volume of the mixture. (Application de l'oscillographe à l'étude des moteurs à explosion. M. Camillerapp. *Revue Générale de l'Electricité*, vol. 1, no. 17, pp. 643-4. 4 figs. *e*)

INTEGRATING TACHOMETERS, Commander L. A. Kaiser, U. S. N.

Description of an integrating speed indicator for use on board ships so designed as to make possible for the engine room to gain or lose distance as directed from the bridge. The bridge determines by stadimeter or otherwise that the ship is ahead or astern of position and directs the engine room to lose or gain. By consulting the previously prepared table kept near the throttle, the man on watch sets the engine hand ahead or in the rear of the clock, and then by the throttle causes the engine hand to lose or gain until it is in coincidence. If the variable gearing in the indicator is so designed that the engine hand makes one revolution per minute when the engine is making the prescribed speed, then it is evident that it is simply necessary to keep the engine hand coincident with the second hand of the clock, which also makes one revolution per minute.

With this in view, a device was constructed on board the *Washington* and installed by the ship's force under the direction of the present writer. It has been in use for nearly a year. This device consists essentially of a 12-in. flat disk of steel, driven by a 4-in. wheel perpendicular to its face and which is driven by a shaft connected by small gear wheels to the starboard revolution indicator. The distance of the driving wheel from the center of the large disk can be varied by a screw of ½-in. pitch. On this screw is placed a scale of revolutions. A clock of 14-in. dial, with a long second hand, is placed over the center of the large disk, the latter carrying a U, over the ends of which an elastic band is stretched across the face of the clock. When the revolutions of the main en-

cases agree with the pointer on the scale, the disk should make one revolution per minute, the I pointer exactly following the clock hand, and, conversely, by moving the scale indicator until the I pointer exactly follows the clock hand, the number of revolutions of the main engine can be read from the scale.

An instrument was built from *Washington* blueprints and installed on the *Connecticut* during the battleship cruise around the world. The fleet engineer reported that the cruise has demonstrated the necessity for some instrument which will show the exact speed of revolutions of the engines at any time. Such an instrument would make it possible for the engines to be run at constant speed, and in changes of speed enable the man at the throttle to take up new speed with practically no loss of time in counting revolutions as at present.

The character of the traction surfaces, that is, the surface of the disk and the rim of the driving wheel, has an important bearing on the correct functioning of this instrument. It has been found by experience that best results are obtained by making the disk of a saw-steel blank and making the rim of the driving wheel of small radius and of hardened steel. In pouring a stream of oil over the point of contact and also in coating the face of the disk with lard, no slip was discovered. (*Journal of the American Society of Naval Engineers*, vol. 29, no. 2, May 1917, pp. 262-267, 1 fig., *d*)

Mechanics

The Laws of Elastico-Viscous Flow, Prof. A. A. Michelson

When a solid is subjected to a strain beyond the elastic limit, its behavior may be summarized as follows:

1 The application of the stress results in a rapid elastic yield which, if inertia be negligible, is practically instantaneous. If the stress be now removed, the specimen returns to its former position.

2 This is followed by a slower yielding, whose rate, if the stress is not too great, diminishes with time, and which ultimately attains a constant value which may be zero. The return to or near its original position depends on whether the stress was or was not too great.

The writer makes an attempt to formulate the behavior of substances under stress by the simplest expressions which have been found to satisfy all the essential requirements, and states that the behavior of any solid under stress may be considered as the resultant of four elements constituting the Laws of Elastico-Viscous Flow.

The *elastic displacement* is characterized by being approximately proportional to the stress and independent of time. A closer approximation is given by

$$S_1 = C_1 Pe^L$$

in which $L = h_1 P$

The *elastico-viscous displacement* is manifested in a slow return when the stress is removed. This displacement is represented by the formula

$$S_2 = A_2(1 - e^M)$$

where $A_2 = C_2\ Pe^N$, in which $N = h_2\ P$, and $M = -\alpha\sqrt{t}$.

The *viscous displacement* applies to the case where the elastic force is absent or very small in comparison with the viscous resistance. For a specimen which has not been subjected to previous strain, the formula is

$$S_3 = (Ft)^{\rho}$$

where $\rho = \frac{1}{2}$ approximately; near the rupture point ρ approaches unity.

A more complicated formula is given for the general case.

The *lost motion* is explained as follows: If the stress be applied for a short time (even a small fraction of a second), the specimen does not return to the original zero. The difference between the original and the new zero is the lost motion. It seems probable that lost motion may be considered as a function of time.

The following notation is used in the above formulae:

S = displacement (twist)
t = time
$F = C_3\ Pe^N$, where $N = h_3\ P$
h, α, constants
P = applied torque.

(*Proceedings of the National Academy of Sciences of the United States of America*, vol. 3, no. 5, May 1917, pp. 319-323, *t*)

Railroad Engineering

Recent Attainments in Locomotive Feedwater Heating

Supplement to the preceding report which covers the subject mainly from the theoretical standpoint, while the present article shows to what extent the savings from feedwater heating have been actually attained through means entirely consistent with American locomotive practice.

These experiments were made with the heater deriving its heat supply from exhaust steam and resembling in its construction a well-known surface condenser. The heat-exchanging elements were ⅝-in. (outside diameter) brass tubes of such number and length as to give a total heating surface of about 120 sq. ft. As the heat transfer is facilitated by the agitation of the water in its passage through the tubes, this result was accomplished in this case by inserting in each a strip of brass of a width equal to the inside diameter of the tube slightly crimped and twisted to a pitch of 3½ in.

While the proportions of the heater were such, and the agitation of the water so thorough as to yield final temperatures within 10 or 15 deg. of the temperature of the exhaust steam, no undue burden was placed on the feedwater pump. The extent of the dropping pressure in the heater was roughly 1 lb. for each 2000 lb. of water delivered per hour. The average initial temperature of the feedwater over a given series of tests was 50.7 deg. In this same series the average temperature of the water delivered to the boiler was 214.5 deg., indicating the average increase as between the inlet and the outlet sides of the heater of 163.8 deg. The proportions of the heater must have been pretty nearly correct for the conditions of test to permit of a very close approximation to the temperature of the steam.

The effect on the quantity of coal consumed was very marked. On the indicated hp.-per-hour basis, the quantity of coal saved was in no case less than 12.9 per cent, this value in one instance being as high as 28.1 per cent.

On the basis of thermal efficiency of the locomotive, the average increase (disregarding the results in three out of ten tests) was 20.3 per cent, and the highest of these values was only 4 lb. in excess of the average, showing consistency in the results.

Since the average increase in the temperature of feedwater was in excess of 160 deg., the theoretical deduction of 1 per cent increase in efficiency attainable through each 10 deg. rising temperature, as indicated in the report of the Fuel Association Committee, is well within the bounds of conservatism.

The original article contains the diagram indicating the relation between water rate and heat expended in pumping and

recovered by feedwater heater. (*Railway Review*, vol. 60, no. 22, June 2, 1917, pp. 753-754, 1 fig., *e*)

Locomotive-Feedwater Heating

Data from a report by a committee, Monroe B. Lanier, Chairman, presented at the Convention of the International Railroad Fuel Association held in Chicago in May.

The economy expressed in the percentage of fuel saving to be derived from preheated as compared with non-preheated feedwater, is in direct ratio as the temperature difference of the water before and after heating is to the difference between the total heat of the saturated steam at a given pressure and the final temperature of preheated feedwater. With other conditions remaining equal, the higher the initial temperature the greater is the percentage of economy per degree rise of preheat. In fact, the writer gives a curve showing that the theoretical fuel saving from preheat follows a straight-line law.

From an operating standpoint feedwater heating is a prerequisite to the best performances and maximum locomotive efficiency. The utilization of preheat permits a freer steaming boiler, increases the confidence of the fireman and leads to an increase in locomotive capacity. An interesting series of curves is given showing the amount of money to be saved yearly by the railroads through feedwater heating.

As to the sources of preheat, the writer indicates that exhaust steam and waste gases may be used for this purpose. The greatest waste seems to be in exhaust gases, but most of it is unavoidable. The writer presents a calculation showing the content of latent heat in the gases and states that experiments have shown that the abstracting of 16 per cent of the exhaust does not, in most cases, require a reduction in the size of the nozzle to get the same vacuum in the front end and the same draft in the fire. A table is given in this connection covering the subject of distribution of heat in a normal locomotive, the same subject being also illustrated graphically.

The next source of heat for preheating water is that of the smokebox. It is impracticable to design an exhaust heater to preheat water from the tank-boiler temperature, but ample space is available in the front end of the modern locomotive, in addition to space required for superheater, units to build a gas heater of sufficient heating surface to obtain a high degree of preheat feeding by means of an injector, the preheat increasing with the velocity and temperature of the gases.

As the final temperature of the feedwater from the exhaust heater is limited to a point below that of the temperature of the exhaust steam, the smokebox heater presents greater possibilities when injector feeding is practiced, particularly with certain types of injectors.

The writer advocates the advisability of the combined use of exhaust steam and smokebox heating, as after utilizing in preheating all of the exhaust steam possible, there is still a margin of 140 to 180 deg. between the feed temperature and that of the water in the boiler. On the other hand, the practical limit of preheating feedwater by means of smokebox gases is that of the boiling point which at 200 lb. pressure is 388 deg. fahr. (*Railway Age Gazette*, vol. 62, no. 21, May 25, 1917, p. 1101-1105, 3 figs., *g*)

Refrigeration

Circulation in Flooded Systems, A. H. Baer

Data of experiments with the glass model of an ammonia-tank coil and an accumulator. By supplying these with liquid ammonia inside, and with ordinary hydrant water—also with ice water—on the outside, the behavior of the ammonia could be plainly observed.

The apparatus used for the test was similar to that shown in Fig. 9 and the experiments were made with the coil nearly filled with liquid ammonia; first, in the open air, then sprinkled with hydrant water, and finally with ice water on the outside. In general, the direction of flow was, of course, upward and out from the upper part of the accumulator. The observers were surprised to see that the gas in the lowest horizontal pipe flowed backward and up through the bottom of the accumulator. Further, the vapor in the second lowest pipe cast out through the bottom pipe and up through the drain pipe of the accumulator. And in doing so it pushed ahead of it a large part of the liquid in the lower pipe, delivering it to the accumulator and raising its liquid level.

The apparatus was then somewhat reconstructed and a greater head of liquid was provided, but this failed to keep the gas in the lower pipes from flowing backward and up through the bottom of the accumulator.

The glass model was then again checked and a check valve

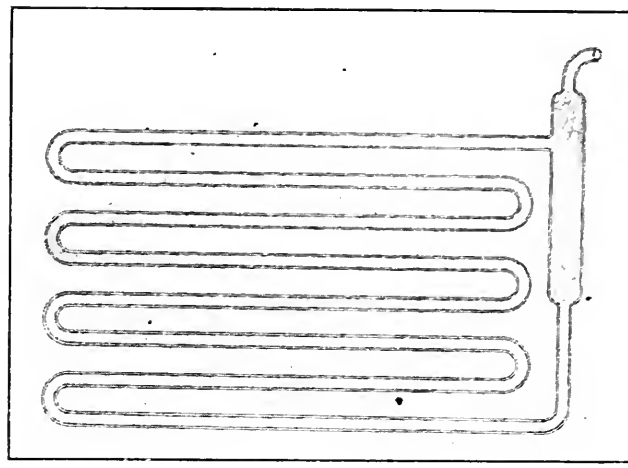

Fig. 9 Glass Model of a Tank Coil and an Accumulator Used for the Study of Circulation of Ammonia in Flooded Systems

was placed in the drain pipe from the accumulator. When this model was partly filled with liquid ammonia and the water applied as before the evaporation of the ammonia was uniform throughout the length of the coil and all gas flowed from the lower pipes up through the entire coil. The gas formed into bubbles which drove ahead of them the liquid, and as the bubbles approach the upper pipe and the outlet of the coils they become larger and the liquid bodies between them become smaller by reason of continual evaporation of some of the liquid while passing through the coils. At the inlet to the accumulator the small amount of liquid remaining between the gas bubbles readily flowed into the accumulator and the vapor only passed from the outlet at the top. The check valve was found to lift when the accumulator became partly filled with return liquid.

The apparatus diagramatically shown in the original was then applied to the ice tank with a check valve especially designed for this purpose. The ammonia feed to the system was purposely arranged to favor lifting of the check valve. Repeated trials showed that the check valve regularly lifted whenever the level of the liquid in the accumulator was raised. Since this variation in level cannot be very great, the check

valve must operate correctly. It has been found that a distance of from [illegible] to 4 ft. between the top pipe of the coils and the bottom of the accumulator is sufficient to provide the necessary liquid head for operating this valve positively and regularly without causing the liquid to fill up more than a few inches in the bottom of the accumulator itself.

This apparatus gave good results and it was thought that the efficiency of an ice plant could be further increased by flooding also the water fore cooler coils. Actually, however, the results were not so gratifying as in the case of the ice tank.

In addition to this the writer describes the present direct flooded system and the so-called submerged flooding system, and discusses the questions of comparative efficiency of plants. (*A. S. R. E. Journal*, vol. 3, no. 6, May 1917, pp. 5-15, 5 figs., *d*)

AMMONIA-AND-WATER MIXER, H. Dannenbaum

Data on the so-called ammonia-and-water mixer specified in the municipal regulations of the City of New York, obtained from experiments made at the factory of the National Ammonia Company, Philadelphia, Pa.

The regulations provide that the refrigerating plants must be equipped with emergency pipes by which, in case of accident, the ammonia can be discharged into water or brought into contact with sufficient water to absorb all the ammonia gas.

The apparatus is constructed so that the ammonia gas can be absorbed by running water, which makes it comparatively simple and inexpensive.

The article describes the apparatus used and the experiments carried out. These experiments have shown that there is a definite minimum amount of water necessary for the successful operation of the mixer, and that when less than this amount passes through, the mixing may cease and ammonia gas enter the sewer. On the other hand, the experiments show that the mixer of the type described properly proportioned will give satisfactory results. A suggestion has recently been made to connect the ammonia mixer to the bottom of the liquid receiver. This would mean that liquid ammonia would be blown into the mixer, but, of course, in considerably larger quantities than the gas. Some experiments have also been made with such an arrangement. (*A. S. R. E. Journal*, vol. 3, no 6, May 1917, pp. 16-19, 1 fig., *d*)

Steam Engineering

RECENT INSTALLATIONS OF LARGE TURBO-GENERATORS, Richard H. Rice

In this paper the history of the development of the General Electric turbo-generator units is first briefly reviewed, beginning with the 5000-kw. vertical machine installed in the station of the Commonwealth Edison Company at Chicago in the year 1903, and leading up to 45,000-kw. units in a single shell now under construction. Without such far-sighted treatment of the situation as has been given by central-station owners, the development of the steam turbine with the rapidity which has characterized it would not have been possible.

A curve is given showing that the steam consumption in 1916 was exactly half of that in 1903. Another curve shows that the price per kw. in 1917 is 42 per cent of that in 1903, and the weight per kw. in 1917 is about 28 per cent of that in 1903. The initial steam pressure has increased from 175 lb. to 300 lb., and the initial temperature from 378 deg. to 660 deg. The vacuum used has also increased from about 27 in. to about 29 in.

Great progress has also been made in boiler-house efficiency. Economizers are being used, and feedwater heaters in the flues are also possible. With the most modern conditions, a boiler-house efficiency of 81 per cent can be obtained with blast-furnace gas.

As a result of all of these improvements, the heat consumption of a complete electric station in B.t.u. per kw-hr. has decreased until it is now about half of the value of 1903. Fig. 10, reproduced herewith, shows the curve.

Estimates are given using information from plants in actual operation of first cost and operating cost of complete blast-furnace and steel-mill plants using respectively gas engines and steam turbines. The plant chosen is one of four blast furnaces, each capable of producing 550 long tons of pig in 24 hours with a coke consumption of 1800 lb. of coke per long ton of pig. The necessary electric generating apparatus for a steel mill has been provided, of suitable capacity to utilize all of the available gas in the case of the gas-engine plant, and to furnish exactly the same amount of power to steel mills in the case of the steam-turbine plant. Some make-

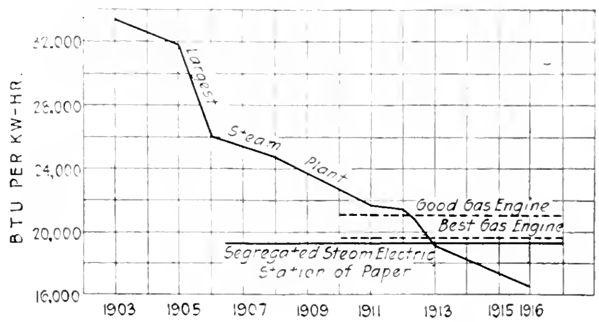

FIG. 10 HEAT CONSUMPTION IN B.T.U. PER KW-HR. FOR COMPLETE ELECTRIC STATIONS ON STEADY LOAD (THE FIGURES IN ALL CASES COVER ALL POWER-PLANT APPARATUS, INCLUDING AUXILIARIES AND EMERGENCY RESERVES)

up coal is required in the gas-engine plant on account of occasional deficiency of gas supply or excessive mill load.

The boilers of the turbine plant have considerable heat-storage capacity and probably would require no make-up coal. However, for conservatism, this is ignored and a small additional amount of coal needed to make the heat balance the same in turbine plant as in gas-engine plant is included in the costs.

A complete outfit of power-plant auxiliaries is included, with such reserve for emergency spares as has been found necessary in practice in the case of gas-engine plants. This calls for steam spares and reserve boilers, capable of being fired by blast-furnace gas or coal in emergencies. Pumping stations are included to supply the demands of the gas washing and electric stations, the blast furnace, and a given amount of water to the steel mills.

This portion of the paper abstracts a previous paper before the Engineers' Society of Western Pennsylvania, March 1917, reviewed in the Engineering Survey, May 1917, p. 461, except that in the present case the boiler plant has been improved by use of modern arrangements previously discussed so as to yield an efficiency of 81 per cent.

In the present case, that part of the plant comprising the electric station is also segregated and independent figures

given. This segregated electric station includes the electric power house, together with that fraction of all parts of the plant directly appertaining to the electric power house, such as boiler house, pumping and gas-washing station, etc. The items necessary to constitute a complete practical modern plant have been included.

Abstracts of the figures and specifications of the plant are given in the appendices to the paper. All costs are based on prices ruling in November 1916.

The overall B.t.u. consumptions of the segregated electric stations of the plants, including all the auxiliaries and emergency reserves, are given in horizontal lines in Fig. 10. The total charges for operation of the plants, including fixed charges, are shown in Fig. 11, first for the complete plant, and second for the segregated electric station.

It will be noted that the turbine plant is very much cheaper than the gas-engine plant, so that the resulting fixed charges taken at 13 per cent are very much less. It will also be noted that the running charges of the cheaper plant are also much the lower. Hence the total charges of the turbine plant are very much lower than the total charges of the gas-engine plant. In other words, the modern steam turbine has reached such a state of development that the modern gas engine is not a competitor.

Utilization of heat units is only one of the secondary operations with which the management of blast furnaces and steel mills is concerned. However, the saving which could be made over existing practice is so large that the author suggests the creation of a separate department of the works to handle the question of power generation, under the control of an engineer of necessary attainments and experience, so that results equal to those obtained by central power stations can be realized for blast-furnace and steel-mill installations.

The utilization of waste heat from open-hearth and heating furnaces (and even from Bessemer converters), the use of by-product gas resulting from the manufacture of coke, and the installation of modern steam-turbine plants at all furnaces, capable of utilizing to the maximum extent possible the heat from the individual furnaces and mills; and the tying together of all plants in a closely developed place like Pittsburgh by electric cables will probably render it unnecessary to develop any power in such a district by the use of raw fuel. (Paper read before the *American Iron and Steel Institute* at New York, May 25, 1917. *hgc*)

THE QUESTION OF THE TAPERING OF THE NOZZLES OF STEAM TURBINES. H. Baer

Deals with the flow conditions in actually constructed turbine nozzles. It was found previously that non-tapered nozzles can advantageously be used for pressure drops far above the critical drop, up to which latter value they are theoretically usable; and the experiments described in the present paper confirm this view. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 60, pp. 646-650, 669-676, August 5 and 12, 1916, through *Science Abstracts*, *Section B—Electrical Engineering*, vol. 20, pt. 4, p. 121)

THERMO-PLUG STEAM BOILERS. Enoch Rector

The thermo-plug steam boiler, Fig. 12, consists preferably of a low cylindrical drum *A*, which in its turn consists of two

flanged heads welded together by the oxy-acetylene process. The heads are properly stayed and the bottom head is drilled and tapped to receive the thermo-plugs, Fig. 13, which have a tapering thread. The plug holes should be as close together as possible, depending on the thickness of the metal and the diameter of the plugs.

The drum is supported by brackets, and the hole enclosed in a spiral coil of pipe *J* wound close and packed together by the oxy-acetylene welding process to form a complete and very rigid outer shell for the boiler. The feedwater is forced through this coil before entering the economizing coil at the top *B*, thereby maintaining the lowest possible temperature on the outside. The economizing coil is suported above the drum into which it discharges, and the flue gases after pass-

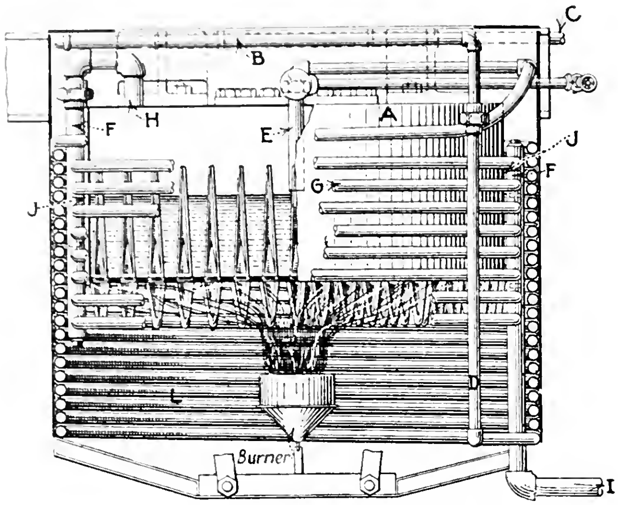

Fig. 12 Thermo-Plug Steam Boiler

ing between the drum and the encasing coil *J* pass between the coils of the economizer.

These boilers have been developed in sizes from 10 to 100 hp. The drums are all 12 in. in height, the diameters ranging from 12 in. to 36 in. The 100-hp. unit consisting of a drum 12 in. high and 36 in. in diameter contains 306 thermo-plugs. It is enclosed in a spiral coil containing 420 ft. of 1-in. pipe and an economizing coil containing 463 ft. of 1¼-inch. pipe. As high as 200 deg. of superheat can be obtained when the

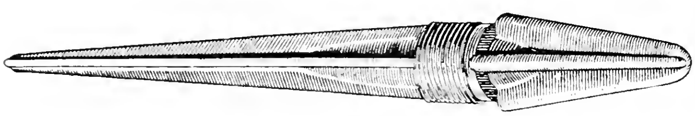

Fig. 13 Thermo-Plug

boiler is forced. The maximum capacity of the boiler is aproximately 420 lb. of water per hour from and at 212 deg. fahr., with an evaporation of 14 lb. of water per lb. of oil. The overall dimensions of the boiler are 4 ft. in diameter by 6 ft. in height, and the approximate weight is 4500 lb.

The external projections of the thermo-plug units should extend into the heated gases with a decreasing section and be so designed as to permit the gases to escape readily. The ends of the plugs projecting outward are made sufficiently long to increase the rate of resistance to heat conduction, so that the ends become incandescent.

In an experimental test in which one burner was used the thermo-plugs in the center became incandescent, while the plugs farthest removed did not show any sign of color. The temperature of the gases 1 ft. above the outer row of thermo-plugs and in passage *J* was 590 deg. fahr. The evaporation was 92 lb. of water per sq. ft. of crown sheet.

The internal projections of the thermo-plugs should be long enough to always extend above the water level. They should have a radiating or wetted surface not less than two-thirds of the external heating surface and they should be tapered to a point with surfaces which permit the ascending steam to escape with the least possible resistance, giving the highest possible velocity. The steam escaping rapidly along these plugs not only assists in keeping the surfaces clean but also drags the water along with it, creating a very violent circulation.

High-silicon cast iron has been found to be the best material of which to make these thermo-plugs, because, among other things, it has a lower coefficient of expansion than the steel of the drum, a condition favorable in this instance to a continuously tight screwed joint.

The writer states that after 3½ years of experimenting with a boiler which has suffered all kinds of abuse, been permitted to run dry a great many times, and had water pumped into it while hot, the boiler is still in perfect working condition and has never sprung a leak. These experiments have all been confined to Newark, N. J., where the water is fairly good.

In the discussion which followed the writer stated that the principle on which the use of the thermo-plugs is based, is the same as that of a target of firebrick in a large oil-fired boiler; the plugs are put in to get high-temperature target surfaces, but at the same time this is the most direct method of transmitting heat through the metal into the water.

In a number of tests water was pumped into this boiler while it was hot. This would be dangerous to do, if the water, in the form of water, could get to a red-hot surface; but with this construction it is impossible to get cold water into the boiler. If the boiler is properly heated there is a large amount of specific heat in the metal which the incoming water will take up while passing through the economizing coils to sufficiently evaporate a portion of it before reaching the main drum.

The boiler is operated at about 300 lb. pressure. Enough economizing coils are put on the top to bring the tenperature of the escaping gases down to 300 deg. fahr. (*A. S. R. E. Journal*, vol. 3, no. 6, May 1917, pp. 20-29, 4 figs., *d*)

The Evolution of the Steam Turbine in the Textile Industry, John A. Stevens, Mem.Am.Soc.M.E., and Associated Engineers

Discussion of the application of the steam turbine in the textile industry, with a brief summary of the history of the development of steam turbines generally. The writer discusses, among other things, the mutual positions of the steam turbine and the steam engine and presents the main reasons for the supremacy of the former, especially in larger sizes. Of particular interest is the following: In the words of the writer, perhaps the most important characteristic of the turbine is the fact that it can be built in almost unlimited sizes. A single unit of 70,000 kw. is now under consideration and larger units contemplated. In this field engine-driven units above 5000 kw. are very uncommon. The largest reciprocating engine known is being installed at the Lukens Steel Company and is to develop 25,000 hp. The largest reciprocating marine engines are capable of developing 20,000 hp.

The paper discusses, among other things, low pressure, mixed pressure, and extraction turbines. The latter also called "bleeder" type, is perhaps one of the most important and convenient developments. It is probably due to the demands of the textile industry, more than any other, that this type of machine was developed. The steam extracted is absolutely free from oil and can be used with great economy without any danger to products in such processes as dyeing, bleaching, slashing, etc., in addition to drying and heating.

The matter of reduction gears is discussed in some detail. From this the writer proceeds to a discussion of the steam turbine on mechanical mill drive. The first application of the steam turbine on a mechanical mill drive of considerable size is said to have been made early in 1913 by the Parsons Company of England, and was a 700-hp. unit for driving a jute mill in Calcutta, India. The turbine was for low pressure, taking steam from old engines. The turbine and engines ran in parallel. The single-reduction gear gave a change of speed from 3000 to 300 revolutions per minute, and the drive from this low-speed shaft to the mill shafting was through ropes.

A considerable number of direct-drive turbines have recently been erected in this country. Of these the writer describes two which he has installed himself. One of these, at the Jackson mill of the Nashua Manufacturing Company, is for 16,800 hp. at 160 lb. steam pressure and with 28 in. of vacuum. It is claimed to be the largest anywhere in use to date. The unit consists of a DeLaval steam turbine with single reduction gear changing from 32,800 to 308 revolutions per minute. Two rope sheaves 64 in. in pitch diameter and each carrying twenty-four 1⅓-in. ropes connect to the two main mill headshafts. The condenser is a Leblanc jet-type condenser located in the basement directly under the turbine exhaust nozzle.

The writer particularly emphasizes the improvement of economy in steam consumption with advance in the art brought about partly by refinements in design and partly by increase in size of the generating units. Two tables in the original article bring out this point very clearly. One of these tables gives efficiency and economy for steam engines driving generators and the other, the same for steam turbines and generators.

From these tables the writer derives the following conclusions: First, the steam engine in the smaller sizes is more economical in the use of heat than the steam turbine. Second, the economy of the steam turbine increases rapidly with increase in size of units. The economy of the latest type of turbine of about 1000-kw. size is practically equal to the best obtainable in the largest and most economical engine built. While the larger turbines are more economical in proportion, the limit of appreciable improvement in economy is reached at about the size of 30,000 kw. Third, the best thermal efficiency reached at the present stage of the art is 26.5 per cent. If, however, all exhaust be used, the thermal efficiency becomes very much higher.

Among other things, the paper describes a new large-size boiler unit designed to be employed in connection with the 50,000- and 60,000-kw. turbines now coming into use in this country. This boiler was developed by a manufacturing company with the assistance of Arthur D. Pratt, Mem.Am.Soc.-M.E., and embodies certain types of general design suggested by the writer. The unit is a complete structure in itself, embodying boilers, superheaters, forced- and induced-draft fan equipment, uptakes, stack, coal bunkers and ash hoppers, even economizers (Fig. 14). This unit is, in reality, made up of four independent sections more completely arranged than has been the usual custom. Any section of the unit may be independently operated while inspecting, cleaning or repairing is going on in the remaining sections. The approximate areas in this unit are as follows:

Grate area..........	936-1108 sq. ft. (projected area)
Water-heating surface.	57,600 sq. ft.
Superheating surface..	14,352 sq. ft.
Economizer surface...	36,800 sq. ft. (contemplated)
Total heating surface.	108,752 sq. ft.

This unit, with one section down for repairs, would easily supply steam for a 30,000-kw. turbine and its auxiliaries, while the entire unit would deliver enough steam to operate a 45,000-kw. turbine. The writer has observed this general type of boiler operating for short periods of time at 400 per cent and over. Under these conditions the entire unit would supply steam enough for a modern 58,000-kw. turbine using high-pressure steam and high superheat.

The unit as shown contains approximately 10.75 miles of 4-in. tubes in the water-heating surface alone. The total length of the 2-in. superheater tubes in one unit as shown is approximately 5.19 miles. The total length of the economizer tubes as now contemplated for one unit is 10.64 miles, or in all, 26.58 miles of tubes per unit. (Paper read before the *National Association of Cotton Manufacturers* at a meeting held in Boston, Mass., April 25, 1917, 39 pages, 22 figs., *hgdA*)

Thermodynamics

Gas Calorimeter Tables[1]

The numerous requests for a brief and concise set of operating directions for a gas calorimeter, and for a convenient set of correction tables, has resulted in the publication by the Bureau of Standards of Circular No. 65, Gas Calorimeter Tables. This may be regarded as a supplement to Bureau Circular No. 48, Standard Methods of Gas Testing. The correction tables are arranged in a sequence most convenient for use in connection with the proposed record sheet.

The record forms for calorimeter tests which are shown in the circular have been used for some time and found to be complete and convenient. It is hoped that these forms will be adopted wherever possible so that there will be greater uniformity in operating methods and the records used. The Bureau is willing to loan the original plates for preparation of electrotypes for these blanks to any one desiring to print them.

The Calculation of the Constants of Planck's Radiation Equation, an Extension of the Theory of Least Squares.[2] Harry M. Reeser

The problem of computing from experimental data the constants, c_1 and c_2, of Planck's radiation equation for the distribution of energy in the spectrum of a black body is attacked by the method of least squares. The data were furnished by Dr. W. W. Coblentz and have been used to determine the constant c_2 by another method. (Bull. Bur. of Stds., *13*, 1916, p. 474).

The observation equations were reduced by taking logarithms of both sides and assigning proper weights to the equations so transformed. The method of assigning weights is given in a general form that can be adapted to any scheme of transformation.

It is shown that the "two-point" method, (Bull. Bur. of

Stds., *13*, 1916, p. 535) of determining c_2 may be made identical with the least-square solution, if all possible pairs of points are combined and a proper system of weights is applied to the separately computed values before taking the mean. This is suggested by T. W. Wright, in Adjustment of Observations, 1884, p. 141. A short numerical example is given to show that this system of weights being applied to an arbitrarily selected number of computed values, the weighted mean approximates the least-square value better than the simple mean.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

Change in Government Boiler-Plate Specifications

As the results of protests of manufacturers of boiler plate that the requirements of the rules of the Board of Supervising Inspectors, United States Steamboat-Inspection Service, governing the manufacture of steel boiler plate are too stringent, and unnecessarily increase the cost of making boiler plate to meet regulations, the executive committee of the board has adopted amendments relaxing the requirements for physical qualities of steel plates and for the drilling of tube and stay holes.

Manufacturers claim that the requirements of the existing regulations add from 5 cents to 6 cents per lb. to the cost of steel boiler plate made to meet the rules of Lloyd's Bureau, without in any way increasing the serviceability of the boilers made therefrom. After examining the evidence in support of this claim, the executive committee has adopted the following rule for physical quality of steel plates:

> The tensile strength determined by the tests shall be not less than 58,000 lb. per sq. in. of section, nor more than 73,000 lb. per sq. in. of section, and the elongation measured in a gage length of 8 in. shall be not less than 20 per cent.

No change was made in the regulation regarding the physical properties of iron plates, the tensile strength of which must be not less than 45,000 lb. per sq. in., with an elongation of not less than 15 per cent. The reduction of area must be not less than 15 per cent for 45,000 lb. tensile strength, and for each increase of 1000 lb. up to 55,000 lb. an addition of 1 must be made to the required percentage of reduction of area.

The board further modified the regulations concerning tubes and stays by striking out of section 15, rule 2, the requirement that "all holes for tubes shall be drilled and no part punched," and out of section 16, rule 2, the stipulation that "all holes for stays shall be drilled and no part punched," substituting therefor the following:

> Centers of guide holes not to exceed 75 per cent of the diameter of the full-size finished hole for which tubes and stays may be punched. The remainder shall be cleanly cut, drilled or reamed to full size.

The amendments have been approved by the Secretary of Commerce and become effective immediately. (*The Iron Age*, vol. 99, no. 23, June 7, 1917, p. 1372)

On May 16 a contract was entered into for the boilers for the first of the ships of the new Emergency Fleet being built under the supervision of Major General Goethals.

The contract for these ships, eight in number, of 8800 tons dead-weight capacity, 426 ft. in length and 54 ft. beam, was recently awarded to the Los Angeles Ship Building and Dry Dock Company.

The equipment comprises four standard Heine marine boilers for each vessel, making thirty-two units in all. Each boiler is to contain 2900 sq. ft. of heating surface. The boilers will be oil-fired and built for 200 lb. working pressure.

In general, the design of these boilers is similar to those installed on the *Minnesota* and also now being installed on the ships of the Luckenbach Steamship Company, building at the Fore River Shipbuilding Company and the Sun Shipbuilding Company.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by July 16 in order to appear in the August issue.

CHANGES OF POSITION

Robert Mawson, formerly associate editor of the *American Machinist*, New York, has become identified with Mawson Brothers, general machinists, of Providence, R. I.

John D. Eberhardt has severed his connection with the Associated Factory Mutual Insurance Companies, Boston, Mass., as draftsman of the plan department, and has entered the employ of the engineering department of the Sayles Finishing Plants, Saylesville, R. I

B. H. Liskow, formerly affiliated with the United Engineering Company, Chicago, Ill., has become associated with the Montague Iron Works, Montague, Mich.

Clifford B. Langstroth, formerly supervisor of the heat-treating and drop-forge departments of the Ross Rifle Company, Quebec, Canada, has accepted the position of metallurgist with the Link Belt Company, of Indianapolis, Ind.

James G. Rollow has resigned as combustion engineer of the Southern California Edison Company, Long Beach, Cal., and has accepted a similar position with the E. I. duPont de Nemours and Company, with headquarters at Wilmington, Del.

Warren P. Doolittle has left the employ of the Waterbury Manufacturing Company, Waterbury, Conn., as designing engineer, and has taken a position as chief designer on development work with the United States Rubber Company, with headquarters at the Shoe Hardware Division, Waterbury, Conn.

Siegfried Rosenzweig, formerly mechanical engineer with the Erie City Iron Works and more recently consulting engineer of the steam-engine department of the York Manufacturing Company, York, Pa., has joined the American Spray Company, New York, in a similar capacity.

Frederick R. Pratt has resigned his position as superintendent of mechanical construction with the Industrial Service and Equipment Company of Boston, Mass., to accept the position of mechanical superintendent with D. Goff and Sons, of Pawtucket, R. I.

C. Edwin Clarke, formerly master mechanic of the Cambria Steel Company, Johnstown, Pa., has assumed the duties of chief engineer of the Wilmington Steel Company, Wilmington, Del.

John A. Lafore, until recently affiliated with the Lafore-Foster Company, Philadelphia, Pa., has become identified with the Merion Paper Company of the same city.

Burt D. Thompson, formerly general foreman of the Base Plug Department of the American Brake Shoe and Foundry Company, Erie, Pa., has accepted a position as superintendent of the L. O. Gordon Manufacturing Company, Muskegon, Mich.

Victor W. Zilen, formerly chief draftsman of the motive-power department of the Long Island Railroad, New York, and until recently a member of the engineering department of Public Service Electric, Newark, N. J., has accepted the position of assistant engineer of the Lucey Manufacturing Corporation of Tennessee, Chattanooga, Tenn.

David J. Bonawitz has become associated with the R. V. V. Company of South Norwalk, Conn. He was until recently in the employ of the Pyrene Manufacturing Company, New York, in the capacity of assistant development engineer.

James H. Pennington, formerly associated with the Public Service Commission of Maryland, Baltimore, Md., has assumed the position of works manager with the Struthers-Wells Company, Warren, Pa.

Thomas E. Raymond has become connected with the Massachusetts Institute of Technology, Cambridge, Mass., as assistant instructor in machine design in the department of mechanical engineering. He was until recently engineer with the Metz Motor Car Company, Waltham, Mass.

A. L. Wilson, formerly combustion engineer of the American Sugar Refining Company, has become affiliated with E. I. duPont de Nemours and Company, as efficiency engineer, with headquarters at City Point, Va.

Harold F. Ely, formerly associated with the Alberger Pump and Condenser Company, New York, has accepted a position with the Westinghouse Machine Company, East Pittsburgh, Pa.

William Sticht has severed his connection with the Singer Manufacturing Company, Elizabethport, N. J., and has become connected with the American Lead Pencil Company, Hoboken, N. J., in the capacity of mechanical engineer.

Louis J. Schneider, formerly sales engineer with the Hyatt Roller Bearing Company, Detroit, Mich., has become identified with the Harrison Radiator Corporation, Lockport, N. Y.

Charles Stadler, connected with the Central Products Company of New York, as chief engineer, has become associated with The Stadler Engineering Company, Chicago, Ill.

J. Alfred Svensson has entered the employ of The New Britain Machine Company, New Britain, Conn. He was, until recently, mechanical engineer with the Meisel Press Manufacturing Company, Boston, Mass.

Prof. John R. Allen, head of the department of mechanical engineering of the University of Michigan, has been offered the deanship of the College of Engineering and Architecture of the University of Minnesota.

Gordon M. Campbell, formerly connected with the General Electric Company, West Lynn, Mass., in the capacity of manufacturing engineer, has assumed the position of works manager of the Kerr Turbine Company, Wellsville, N. Y.

William J. Adam, recently superintendent of The Regina Company, Rahway, N. J., has become associated with the Fickling Enameling Corporation, Long Island City, N. Y., and the Davis-Bournonville Company, Jersey City, N. J., as general manager and management engineer respectively.

Gail H. Browne has accepted a position with the Lehigh Valley Transit Company, of Allentown, Pa. He was formerly in the employ of Ford, Bacon and Davis, New Orleans, La.

Samuel C. Weston, recently associated with the Remington Arms Union Metallic Cartridge Company, Bridgeport, Conn., as safety engineer, has entered the employ of Bayles Shipyards, Inc., Port Jefferson, Long Island, N. Y.

George B. Rice, formerly consulting chief engineer of power and manufacturing equipment of Schoellkopf Aniline and Chemical Works, Inc., Buffalo, N. Y., has assumed the duties of general superintendent of the disk record division of Thomas A. Edison, Inc., Orange, N. J.

J. Charles Strott has severed his connection as chief engineer with the Curtis Bay Chemical Company, Curtis Bay, Md., and has entered the maintenance department of the Bureau of Yards and Docks, Navy Department, Washington, D. C.

ANNOUNCEMENTS

P. H. Troth, second vice-president of The Fairbanks Company, is now manager of the New Orleans, La., branch of the company.

Lester G. Briggs, chief engineer of The Fairbanks Company, New York, has been transferred to the Buffalo, N. Y., office of the company in a similar capacity.

Victor W. Kliesrath, for many years chief engineer of the Bosch Magneto Company, New York, has severed his connection with that concern, after a long and successful period as head of the main office, and the technical and engineering departments. During Mr. Kliesrath's association with the firm many improvements in the product were evolved, and he was largely instrumental in bringing the starting and lighting equipment up to the high standard it has attained at present. His plans for the future have not, as yet, been announced.

Norman L. Snow, associated with The Terry Steam Turbine Company, Hartford, Conn., for the past eight years, has recently been elected vice-president of the company.

Through an error announcement was made in last month's Journal that Emile H. Nate had severed his connections with the Nate-Earle Company, Inc., of New York. Mr. Nate is still president and treasurer of the Nate-Earle Company, Inc., and is also acting in a consulting capacity to Hammerston and Nate of New York.

William Mason Towle, professor of industrial engineering at Clarkson College of Technology, Potsdam, N. Y., retires from active service at the close of the present academic year. The trustees have appointed him professor emeritus of industrial engineering.

Charles Whiting Baker has established offices as consulting engineer at 31 Nassau Street, New York.

APPOINTMENTS

Walter J. Sykes has been appointed chief draftsman of the Canadian Copper Company at Copper Cliff, Ont., Canada.

Herbert W. Alden, vice-president of the Timken-Detroit Axle Company, Detroit, Mich., has been appointed a major in the ordnance department.

H. L. Worrois has been appointed chief engineer and production manager of the A. J. Detlaff Company, which is opening a new clutch department to manufacture a new design of disk clutch for automobiles, trucks and tractors.

Harry W. Townsend, formerly factory manager of the Aldrich Pump Company, Allentown, Pa., has been appointed office manager and sales engineer for Western Pennsylvania, for the same company, with headquarters in Pittsburgh, Pa.

Arthur R. Carlyle has been appointed official surveyor for the American Bureau of Shipping, American Lloyds. Mr. Carlyle still retains his position as marine engineer for the Union Oil Company of California, Los Angeles, Cal.

Charles W. Nickerson, for the past nine years in the engineering department of the Westchester Lighting Company, Mt. Vernon, N. Y., has been appointed an assistant naval constructor in the Naval Coast Defense Reserve, U.S.N.R.F., with the provisional rank of Lieutenant, being detailed on Government work in the Third Naval District.

Louis J. Hirt, formerly vice-president of the Pearson Engineering Corporation, New York, has been appointed consulting engineer for the United Gas and Electric Engineering Corporation, and will supervise the construction and engineering work of the subsidiary companies.

THE NEW BOOKS

ALL books received by The Journal will be listed under this heading, generally accompanied by brief descriptive notes. Works of special importance to mechanical engineers will be commented on at length by members and others peculiarly qualified by reason of their experience and training.

Practical Safety Methods and Devices

Practical Safety Methods and Devices. By George Alvin Cowee, E.M., S.B. D. Van Nostrand Company, New York, 1916. Cloth, 5½ x 9 in., 434 pp., 128 illustrations. $3.

The author in his preface very properly sets forth the enormous human loss involved in the annual accident roll of this country. This roll now exceeds the combined annual losses of the Union and Confederate armies during the Civil War. In his introduction he gives some indication of the enormous financial losses as a result of this great waste of human power.

The book is intended to provide for employers, superintendents, foremen, underwriters, safety inspectors and engineers generally, a convenient summary of standard safety methods and devices developed and approved by those who have specialized in this subject. In the introduction the author clearly indicates that mechanical safeguards alone can only prevent about thirty per cent of the preventable accidents, while at least sixty per cent of such preventable accidents can be eliminated by suitable educational methods and regulations. He states that, in his judgment, ninety per cent of all accidents of workmen are actually preventable. He is justified in this claim on the basis of the past experience of those who have given full and careful attention to the subject in the shops. The claim which he makes that accident-prevention activity is a paying investment is also well verified by practice.

The author very properly begins the body of his work by a chapter upon the organization of safety committees. He indicates the necessity of such committees and shows how they may properly be organized for different-sized establishments. Thus, he would have a central safety committee, consisting of a trained officer of the plant, a safety inspector and a foreman or representative from each plant division. He gives very excellent tabulations of the duties of this committee and of the individuals of its constituent membership. He then shows the wisdom of having under this centralized committee, workmen's committees for each department, the membership of which is of limited duration and is arranged so that there are periodical changes of personnel. In addition to detailed information as to individual work of the inspection committees, much valuable information is given as to general educational methods. Thus the author takes up the problem of periodical talks and lectures; motion pictures where available; the use of safety bulletin boards and what they should contain; competitive team work; the offering of prizes; etc., etc.

A full discussion of the general conditions to be found in the shop is included under such headings as Guarding Machinery; Danger Signs; Clothing; Congested Work Places; Ignorance; Intoxicants; Fatigue; Illness; Thoughtlessness and Carelessness; Concentration; Instruction; Discipline; Inspection; Education of Children and Students; and the Education of the Public. These titles in themselves are illuminative and indicate the general proper treatment of the subject. A chapter is given to proper buildings and the elimination of the fire hazard. A careful discussion is made on methods of fire egress, fire fighting, fire drills and fire prevention. A very succinct and brief though satisfactory chapter is devoted to the organization and handling of fire brigades. A practical discussion ending with a set of boiler rulings is given on the type, handling, and care of boilers, following in general the instructions called for by the Code of The American Society of Mechanical Engineers. This is followed by a discussion of steam engines, care relating to their operation, safety stops, speed-limit stops, flywheels, etc. A set of engine-room rules is appended to this discussion. An even more extended discussion is given to the elevator, in which the dangers of this apparatus are clearly brought out and methods for correction given. A chapter is given on the principles of protecting against electrical hazards to life.

Following this is a chapter on transmission machinery, showing illustrated examples of many of the most important types of guards, and describing the underlying principles of such guarding. This is followed by chapters on machine tools, grinding machinery, woodworking machinery, and machines of miscellaneous types. In all of this work, evidently the attempt of the author was to lay down fundamental principles, giving, so far as necessary, illustrations.

A chapter is devoted also to the manufacturing of iron and steel, in which the points distinctly relating to actual production are developed.

Following this the book takes up the most important problems relating to the hazards of handling and storing material and of construction work, dealing with them in much the same manner as with the other subjects mentioned. The book then enters into the subject of safety as related to steam and electric railways, and mining and quarrying. Following this is a long chapter on explosives.

Under a miscellaneous chapter are discussed the subjects of eye protection, respirators, hand tools and their dangers, ladders, traffic, etc. This is followed by a fine set of rules for foremen, and general rules for the shop, and this again by a discussion on sanitation, illumination, heating, and ventilation. In the succeeding chapter on welfare work the author states that often no expense is being spared in making the living and social conditions among the workers as pleasant and attractive as possible, and further that the result of this welfare work is directly reflected in the quality and quantity of the work performed, and the loyalty and efficiency of the employees. The author in making these statements refers to the activity of a number of large corporations in this country. He gives a brief but illuminating discussion of the purpose of welfare work, and the organization necessary to perform it. This is followed by a discussion of occupational diseases and first aid to the injured. An appendix is given upon the subject of asphyxiation or suffocation, including methods of resuscitation by artificial respiration.

As indicated from the discussion above, the book aims to cover a very wide range of industrial activity. Its author's intent, therefore, is, undoubtedly, to bring out the underlying

[illegible] and welfare in the various fields he has dealt with under three general captions: detailed safeguards and methods; the economic and social conditions of industry. Indeed, to do the latter would require a series of volumes the size of this one. He has apparently succeeded quite well and the book should prove a valuable reference to those engaged in industry or those who are making a study of the subject.

The author seems to be particularly commendable on the many recommendations of practical devices suitable for industrial practice. [illegible] comprehensively and without breaking the [illegible], and should prove of distinct value to those [illegible] engaged in industry. The book is well [illegible], illustrated with carefully selected and fairly clear illustrations. It undoubtedly is the result of a large amount of [illegible] cooperative labor on the part of the author and the publisher.

JOHN PRICE JACKSON.

Valuation, Depreciation and the Rate-Base

Valuation, Depreciation and the Rate-Base. By Carl Ewald Grunsky, Eng. D., Member of the American Society of Civil Engineers, assisted by Carl Ewald Grunsky, Jr., E.M., Member of the American Institute of Mining Engineers. John Wiley & Sons, Inc., New York, 1917. Cloth, 5¾ x 9 in., viii + 387 pp., 27 illustrations. $4.

The purpose of the book is the discussion of the various problems connected with the valuation of property, principally that of public utilities, the proper method of treating depreciation, and the determination of a base rate which will be equitable to the public and yield a reasonable return to the owner.

The thoughts advanced are based largely on the long experience of the author in connection with such work, and are given out for the assistance of others who may be engaged in similar work, and for the purpose of developing further discussion toward the standardization of these problems.

The author urges at considerable length and forcefully that the base rate should be on the full normal replacement value, without depreciation, as against present value—used by many authorities and as ruled in many court decisions. The author's method is the proper one to follow and sets forth the principle on which all fixed charges must be estimated in any public or private enterprise which it is expected will continue for many years and beyond the life of many of the elements which go to make up the whole property.

In the consideration of normal replacement value, that is, value as determined by average costs of a series of years, it is stated that there should be added to the value of the physical property all proper overhead expenses, the cost of organization, the legitimate expenses during such a period of time as it would take under ordinary conditions to build up the business to a profitable basis, and the value of intangible property such as water rights, etc.

This statement is agreed to by most all engineers, but not always by the Courts. All of the above would seem to be proper elements of expense which must be met and a proper allowance should be made for them, the only debatable thing being the extent to which they should be carried.

The elements affecting the increase or decrease in the value of properties are discussed and recommendations made as to the proper application of the same.

The amount of unearned increment of value which should be allowed to the owners in determining the base rate is also discussed.

There is also discussed the treatment of overdeveloped properties and the wisdom of having a reasonable margin of capacity for increase in business at a reasonably early date.

The various methods of treatment of depreciation and amortization are discussed at length and the author urges with great earnestness the use of what is defined as the Unlimited Life Method for the treatment of depreciation.

The different courses followed in the valuation of property for various purposes, as purchase and sale, rate fixing, taxation, etc., are described.

The difficulties of determining with definiteness the value of mining and oil properties is explained and an argument made for the taxation of such properties based on output rather than on the physical features of the properties.

The necessity of a careful accounting system in order that all interests may be dealt with intelligently is urged.

The book contains many tables containing valuable information, and those at the end on Probable Useful Life, Expectancy and Remaining Value, and other actuarial tables, many of which have original arrangements, would be helpful to any one engaged in this kind of work.

The subject-matter is clearly developed and illustrated by many worked-out examples. The material is largely original, as is also its presentation, but it necessarily contains much which is common to textbooks on this subject.

The publication will be helpful to advanced engineers and appraisers. It is probably too far advanced to be used as a textbook for students.

CHAS. T. MAIN.

The Industrial and Artistic Technology of Paint and Varnish. By Alvah H. Sabin. John Wiley & Sons, Inc., New York, 1917. 2d ed., cloth, 6 x 9 in., 473 pp., 18 illustrations, including 8 plates. $3.50.

This book has been written to give a correct general outline of the subject, with a brief account of the modern use of paints and varnishes, and the principles involved in their fabrication and application. This edition is nearly one-third larger than the first one and takes cognizance of the changes in the character of the cheaper varnishes due to the use of tung oil.

How to Find Factory Costs. By C. Bertrand Thompson. A. W. Shaw Co., Chicago, 1917. Cloth, 6½ x 9½ in., 191 pp., 53 illustrations. $3.

The author has endeavored to make this book broad enough to apply to all kinds of industries, and it is intended to be useful to the accountant as well as the factory head. Contents: What a Good Cost System Means to You; What Goes to Make Up Your Costs; How to Handle Indirect Costs; What About Interest and Depreciation?; Charging Each Unit with Its Proper Share; The Machine Hour Rate Plan; How to Handle the Cost of Selling; Tying the Costs Into the General Accounts; An Effective System of Classification; Taking Factory Costs Apart; A Cost System that Safeguards; Making Costs and Bids Agree.

The Naval Architects' and Shipbuilders' Pocket-Book of Formulas, Rules, and Tables, and Marine Engineers' and Surveyors' Handy Book of Reference. By Clement Mackrow and Woodland Lloyd. The Norman W. Henley Pub. Co., New York, 1916. 11th ed., flexible leather, 4 x 6½ in., 742 pp., 12 illustrations. $5.

In the present edition a new section on speed and horsepower has been inserted, together with a brief description of modern methods of powering and determining forms suitable from a propulsive standpoint. The sections on strength of materials, riveted joints, and stresses in ships have been considerably extended, and information on British standard sections, screws, keys, etc., has been added.

MOBILE ARMAMENT FOR DEFENSE

By ANDREW M. COYLE, NEW YORK, N. Y.

Member of the Society

This paper points out the general features of the several types of mobile armament which have been developed in Europe, as an aid to the engineers of this country who will now have to take hold of the problem of developing this means of defense.

The author emphasizes the importance of the roadway, a factor which must be carefully looked after and in the direction of which an enormous amount of work remains to be done.

He reviews the history of the armored and armed automobile from the inception of the common automobile provided with slight protection and armed with a machine gun, to the present "tanks." He also describes the development of the armored railway car.

The paper concludes with a description of the various methods proposed for meeting the requirements of heavy mobile guns. Of interest are descriptions of a new system of recoil for mobile guns and the author's non-recoil coast-defense gun, in which latter the breech block abuts upon a hardened steel spherical segment and the reaction at the time of explosion is transmitted to a heavy concrete foundation as a static load.

BROADLY speaking, the subject "Mobile Armament for Defense" would cover every weapon and engine capable of being transported from place to place and used to repel an enemy. I shall, however, confine my remarks to one important branch of land equipment—to those weapons and engines which have been recently developed and present points of novelty both in construction and military value, namely, armed and armored automobiles and railway cars, and heavy mobile guns. These are all in process of development and offer many problems for the engineer.

The prospect of valuable development along these lines is particularly good in this country, for the reason that we are starting with a clear field. We are not bound by types which, constructed under emergency, have to some extent become fixed in the armaments of other countries. We are free to select the best types so far developed and to add thereto the finishing touches of American design.

It is my purpose to point out briefly the general features of the several types of mobile armament which have been developed in Europe, so far as the meager information obtainable permits. Also to explain the simple mechanics involved in the problems presented. I shall, of course, not attempt to describe the armaments now being designed and built by the War Department of the United States. I hope, however, that some of those present will study the problems and be ready to render practical assistance in the work before us.

War in Europe has assumed many of the aspects of a siege. In this country the same condition could not exist, for the reason that we have not the same density of population. We must, therefore, be prepared for the greatest possible mobility of our army and the highest efficiency in our mobile armament.

Our coast line is of such extent that it cannot be defended by any navy we are likely to build or would be able to maintain. Our important harbors, will, of course, be protected by permanent works, but for the defense of all the rest of our coast, we must depend, after the Navy, upon heavy mobile armament. The medium and light mobile equipment is a strong—I might say almost indispensable—adjunct to land operations.

I must digress at this point to comment on the singular mental attitude of some of our good citizens who even today do not realize the imperative necessity of complete military equipment.

Right thought is the foundation of all progress. The first step, therefore, toward mobile armament is to mobilize the wits of our people. If we could only lay hold on the thoughts of these complacent locally minded people—place them on wheels—or even wings—as the Army is doing with our guns, if we could cause them to travel north, south, east and west over our land and to comprehend that this is a land of States United and that it behooves each individual to sacrifice something for the common good, we would accomplish a mobile armament of greater national value than that which shall be wrought in bronze and steel, important as that is.

THE MILITARY IMPORTANCE OF GOOD ROADS

The next important step toward mobile armament is the roadway. The day of field artillery has not passed. The types of carriage and limber which we saw pictured in our school histories as drawn by dashing horses through furrowed lanes and ploughed fields or by men laboriously up mountain sides, are not to be thrown on the scrap heap, though, when possible, motors will take the place of animal power. Roadways are more important in warfare today than ever before. Great military operations have always followed roadways, and as equipment becomes more and more cumbersome and beyond the carrying power of man and beast, roadways must be ever more carefully looked after.

This second step in mobile armament is one of even greater economic than military value. It is difficult to think of any part of the country in which railroads and roadways constructed with reference to military utility would not be of the greatest commercial advantage. At present our avenues of transportation are established mainly with reference to immediate business requirements. Under other conditions they might be established upon a general and comprehensive plan.

I have already mentioned the impossibility of protecting our coast by fixed fortifications. The Navy having been overcome or outmaneuvred, there are a great number of places on our coasts where an enemy could make landing in force—places where, under the protection of the enemy's fleet, thousands of men could be landed in a few hours. While in time of war

Abstract of paper presented at a meeting of the New York Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, March 13, 1917.

each of these places a point of danger, in time of peace many of them are possible harbors. The same roadways which would transport mobile armament would open these harbors to traffic.

Parallel to our eastern coast we already have trunk-line railroads. It is a matter of no great difficulty to extend branch roads to the points of greatest strategic importance and to make surveys and all necessary arrangements to enable our military engineers to construct other branches on short notice. The difficulties are mainly legislative and political. Before this plan can be inaugurated, however, many questions must be settled both as to right of way and as to methods of operation and maintenance. These branches should, if possible, be operated so as to yield a profit.

While in the past few years we have made enormous improvements in our wagon roads, but there remains an enormous amount of work to be done. Here again we find the necessity for cooperation between the national and local authorities.

Obviously, every trunk line and branch should be paralleled by a wagon road capable of standing heavy traffic. By parallel I do not imply proximity. For many reasons it may be desirable to have the trunk lines some distance apart in order that the lines may be separately defended.

Our bridges must be carefully considered. We need many new bridges, and they should all be strong enough to permit of the transportation of heavy ordnance.

For forty years the subject of good roads has been agitated for economic reasons. Let us hope that the present movement toward military preparedness may cause this good work to take definite form and go forward.

We now come to the consideration of the armaments which shall pass over these good roads—when we have them built, or which may have to struggle along on some of the roads as they already are. The defence of the nation will depend upon the equipment of the army. The day when men could be called hastily into action is passed. Numbers and valor count for but little against equipment.

ARMORED AND ARMED AUTOMOBILES

The first machines developed were common types of automobiles provided with slight protection and armed with rapid-fire or machine guns. The rapid-fire gun is necessarily of small size (about one pound), for the reason that the recoil of a heavier gun would be too much for the car. This type of machine is very effective for guarding roadways and may participate in offensive movements, provided it can be operated from some point of safety. The shields protect only the gunners and not the working part of the machine. Its use is to carry these light guns rapidly from point to point. It is not possible to armor automobiles against anything heavier than a rifle bullet, for the reason that armor plate of sufficient weight to withstand even a 1-lb. projectile would make the machine too heavy for service.

These light armored automobiles were improved upon by the British, who developed heavier cars with turrets. These cars were not of graceful design, but are said to have done excellent service. The gunners are well protected, but the running gear is not protected at all. The advance of these machines may be stopped by concentrated fire on the running gear.

The Italians later developed turret machines of more graceful design. At first no attempt was made to protect the running part of the machine, but the gun and gun crew were very well protected; in fact, the machine is a small fort on wheels which can be quickly transported from place to place, but it always will be necessary to use it in a road "cut" or behind some barrier which will protect the running gear from damage. A shield of light armor plate is provided over the engine and furnishes fairly good protection.

In a later Italian machine the wheels are protected. Bars in front are provided to cut barbed wire. These two types of Italian machines are said to be the latest and best types of armored automobile. They are certainly the best in appearance.

The French have developed machines specially designed to carry a Schneider anti-aircraft gun, which is mounted upon the rear of the machine. The gun used on such machines is necessarily small and would not be able to reach an aircraft at a high elevation, but the extreme mobility of the gun renders the outfit a very effective weapon. The Schneider recoil system is very efficient. As the range of elevation of these guns is from zero to zenith, they are effective in any situation and the term "anti-aircraft" is to some extent a misnomer.

The French have made successful use of motor trucks for transporting small howitzers. The howitzers are not fired from the trucks but are skidded off when they are to be put in action. This operation may be accomplished in about the same time it would require to unlimber regular artillery.

The skid-mounted howitzer is a very convenient arrangement—it may be fired from all sorts of positions, from the trenches and from behind low breastworks. When the howitzers are at work the trucks are out of the way. The motive power is withdrawn out of range just as in the case of horse-drawn guns. If the guns remain long in one place the trucks are available for other purposes.

The Davis non-recoil gun is interesting as being the only weapon so far developed which does not react when fired. This result is accomplished by firing a charge from both ends of the gun. That fired toward the rear being of shot and vaseline, breaks up soon after leaving the gun. A round of ammunition for this gun weighs about one and six-tenths times as much as a round of ammunition for a 3-in. field gun. The energy imparted to the Davis 12-lb. projectile is about one-third of the energy represented by the 15-lb. projectile fired from a 3-in. field gun.

If we compare the work done by these two guns on the basis of the amount of energy delivered from the muzzle, it will be seen that the amount of ammunition necessary to be carried to produce a given quantity of muzzle energy is as 4.8:1.

If any way can be found to lessen the reactive force due to recoil without greatly increasing the distance of recoil, it will be of material advantage. In this case the method is so wasteful of material that it is only practical to use it in very extreme cases. I will speak further regarding the question of recoil.

Under the head of automobiles we may consider the "tanks" which have been used by the British. Their primary purpose is for direct frontal attack. They are sufficiently powerful to break down barbed-wire entanglements and will cross trenches, provided the trenches are not very large and the ground about them is solid. But the weight of these machines is so enormous that they will crush in anything but the most substantial ground. The remarks about the weight of armor which can be used on automobiles apply to some extent to these tanks. A direct blow from a 15-lb. projectile will put the tank out of commission. Their armor is heavy enough to withstand glancing blows from quite heavy projectiles. The progress of one of these machines is necessarily rather slow and the enemy should have time to bring into action guns of sufficient size to disable the tank before it has gone very far. I do not think that machines of this kind would be of any use in this country, although they have been of some value on level fronts in northern France.

The new "tanks" of French design are made to crush

through wire entanglements. They have abandoned the trench-crossing scheme tried by the English, which has evidently turned out to be of little value.

ARMORED RAILWAY CARS

The first armored railway car ever used in warfare was constructed in this country. It was built under the orders of General Robert E. Lee, who was an engineer officer and at an early stage of the Civil War saw the value of this equipment. During the Boer War the British developed an armored car (Fig. 1) which is interesting as being the prototype of the modern car of the U. S. Army. The car is divided into three compartments. Those at the ends afford protection to riflemen. The central compartment, which is lower than the ends, is the magazine. Upon the top of the magazine is mounted a 3-in. naval gun.

Complete trains are formed of cars carrying guns accompanied by box cars carrying ammunition and light armored cars. Outriggers are provided for stabilizing the gun cars. Some stabilizing device has to be used on all cars from which guns of large size are to be fired. When in operation, the heavy guns are separated from the rest of the train, the armored cars being used to protect the track against surprise attacks.

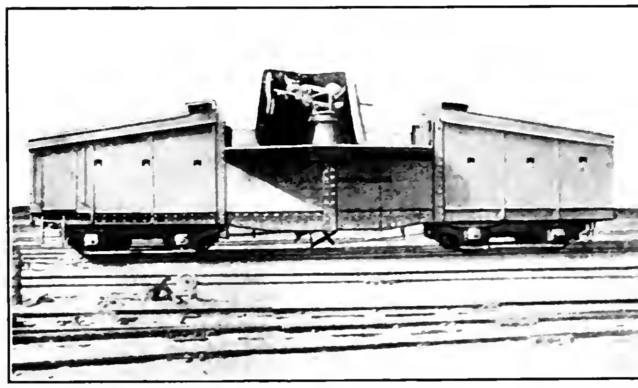
The first modern car built in America (Fig. 2) was constructed on short notice when trouble with Mexico was anticipated. It is a steel box erected upon the platform of a railroad car of standard type. The stakes of this car afforded an excellent support for the steel plates. The port holes are for rifle fire and machine guns. In the center of the car is a well in which a 3-in. field piece is mounted upon a special carriage. The peculiarity of this carriage is that the gun is traversed in azimuth about a center which is nearly below the breech of the gun instead of below the trunnions as would be the case in a pedestal mount. This arrangement provides a clear space back of the gun in which the crew can work and avoids the necessity of extended platforms such as used on English and French mounts.

There are being designed some new types of armored cars which embody great improvement on those shown. I, of course, am not at liberty to show these designs.

It is highly important that an armored car should be provided with independent motive power. While these cars are sometimes used in trains, their most valuable service can be rendered independently, each car patrolling a certain portion of railroad and being continually on the lookout for surprise attacks by the enemy. Of course, an armored car operating on such duty cannot go far from its base, otherwise it would be liable to capture, as is the case with any other detached unit.

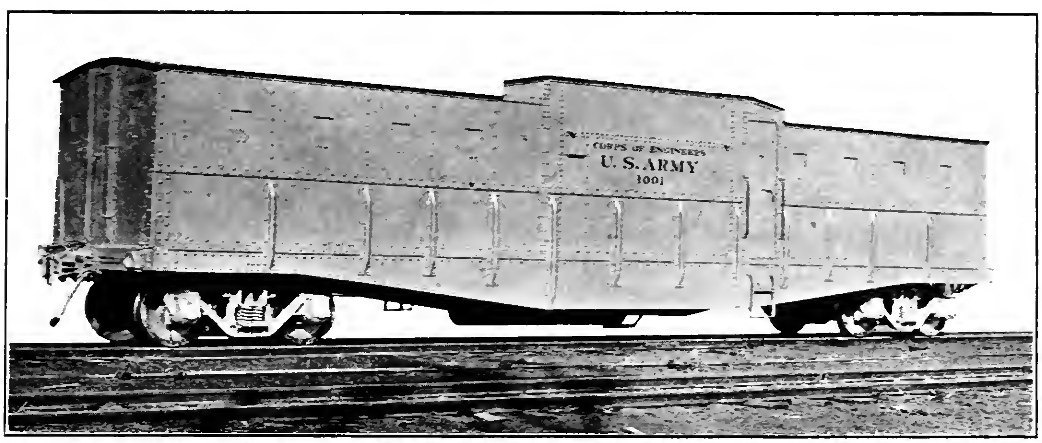
The motive powers available are storage batteries, motor-generator sets operated by Diesel or other internal-combustion engines, steam and also direct-connected gasoline engines.

There has also been developed an arrangement of a gasoline motor suitable for driving an armored car, or, for that matter, any other car. In this construction the middle sill of the car is replaced by two very deep girders separated about six feet. The gasoline engine is of the V-type and should be of not less than 100 hp. It drives the car through a jointed transmission similar to that used on large motor cars. The location of the joints used in this shaft is such that the movement of the truck about the car center is in no way interfered with. The reverse gear is operated in the gear case which is on the wheel shaft, and the pinion may be thrown out of mesh so that when the car is connected up in a train there is no idle machinery in motion. Within the space of this deep center girder the oil tanks, air brake and other vulnerable parts may be located, the web plates of the girder being made of sufficient thickness to resist penetration.



Engineering.

Fig. 1 British Armored Car with 12-lb. Naval Gun Mounted in Center



Standard Steel Car Co.

Fig. 2 First Modern Armored Car Built in America

Before discussing next class, I will call attention to a new type of coast gun which is not mobile.

Fig. 3 is a coast gun. The peculiarity of the gun is that the breech block does not screw into the gun and that the gun does not recoil. The breech block is a simple plug provided with a gas check. This block abuts upon a hardened-steel

surface which is curved, the curve being concentric with the trunnions of the gun. The reaction at the time of explosion acts as a static load upon the abutment. There is no mass in motion. The abutment member is traversed in azimuth in a casting which is a spherical segment. The concrete foundation must be sufficiently massive to stand the static load imposed.

The projectile is brought to the gun upon a carriage which travels about the center of the mount. The power to traverse and elevate the gun, also the electric wires, are brought through a conduit which terminates at the center of the mount. This gun does not disappear, but the splinter-proof housing is small and inconspicuous, and may be concealed from the enemy until he is within close range. The gun has all-round fire and may be elevated to any desired angle up to 30 deg.

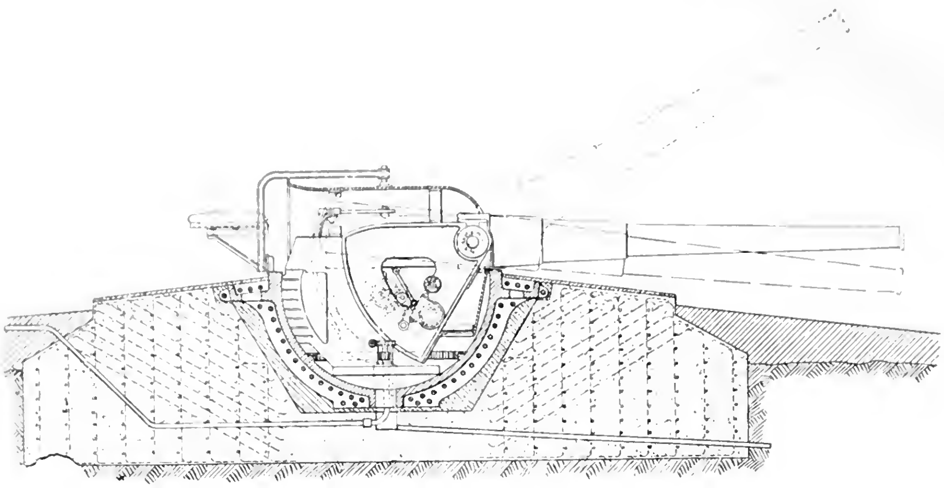


Fig. 3 Section of Coast-Defense Gun with Spherical Mount

HEAVY GUNS ON RAILWAY MOUNTS

We now come to the most important railway armament, i. e., the mounting of heavy guns upon railway cars. We may divide this equipment into two classes: First, guns of high power to be used against vessels at sea. These guns are necessarily fired from locations which have been carefully predetermined and to some extent prepared. They are never fired from main-line railway tracks. The second comprises guns of from 4.7-in. to 8-in. caliber and is useful to prevent landing or to check the enemy if he has made a landing.

In their operations in Belgium the Germans used large howitzers which were not originally mobile weapons. They were fired from previously prepared foundations. When placed upon such a foundation the fire of a gun is, of course, much more accurate than that of a mobile gun. The best foundation is of concrete, but a more quickly constructed foundation may be made of heavy timber bedded in clay, sand or cement. A foundation of this kind will stand a number of shots before it gets seriously out of level. These guns are transported, either assembled or in parts, upon flat cars. They are lifted off and placed upon their foundations by ordinary cranes and may thus be considered as a part of mobile armament.

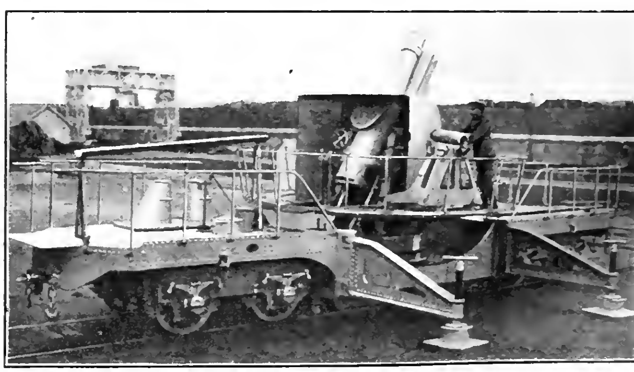
Fig. 4 shows a car of French design carrying a moderate sized howitzer. It is necessary to use outriggers in order to stabilize the car when the howitzer is fired. As depicted, on level ground this system works out very well. If the ground is not level, footings must be built up to receive the jack screws. There is provision under the car for locking to the track, so as to resist movement in a horizontal direction. The tendency is for the car to be lifted from the tracks. The center of action is the point of the jackscrew. Should the track shift there is, of course, a tendency to bend the screw, which may result in trouble if the screw is extended.

A railroad track will not resist a very great force applied transversely. About 30 per cent of the load on the track is a maximum. As the tendency is to lift the car when the gun is fired horizontally, the full weight of the car cannot be considered in making allowance for the resistance of the track.

SCHEMES FOR MEETING THE REQUIREMENTS OF MOBILE GUNS

We may now consider some of the schemes devised to meet the requirements of mobile guns.

In Fig. 5 the system of outriggers used on the French car just described is shown at (a). It will be seen that if it is fired from a location when the ground on one side of the track is sloping, a certain amount of blocking will be necessary. The overturning moment is A/B; the center of action is at C. Another arrangement is shown at (b); the outriggers are nearly on a level with the car platform and are supported by struts or jackscrews which are free to move about the centers C, C'. The overturning moment is A/B. The entire side thrust must be provided for on the track. The tendency to bend the jacks is eliminated. If the ground beside the track is low, the jacks are lengthened, no blocking being required. At (c) is shown a system of blocking the car upon the railroad ties. The base B is short, but if the car is heavy, a good-



Illustrated London News.

Fig. 4 French Car Carrying Howitzer

sized gun may be fired from a car blocked in this way. It is certainly very desirable to work within the limits of the roadbed, as we are then fairly certain of the conditions we shall find, and know that we can fire the gun from any point along the road without previous preparation.

When we fire a gun horizontally, the center of action may be kept low, but when high-angle fire is required, we find some difficulties. The trunnions must be placed higher, not only to allow for the actual swing of the gun, as shown at (d) in Fig. 5, but to allow for the recoil as shown at (e). This increases the overturning moment when the gun is fired horizontally.

This principle of double recoil is important in mobile armament. The car is blocked, as shown at (c) in Fig. 5. A car blocked in this manner will stand a very great force applied downward. Its horizontal stability is, however, much less. The principle of double recoil involves the use of one recoil system parallel to the axis of the gun: this system offers heavy resistance, the movement being quite short. The carriage is free to recoil in a nearly horizontal direction upon a long slide. The resistance to the horizontal recoil is not great enough to affect the stability of the car. This principle was used in some of the older types of carriages in which the recoil along the slide was inadequate and the carriage was allowed to recoil horizontally, being checked by a friction brake or a "brake cylinder."

It has been found convenient to develop several formulæ for determining approximately the working strains and distances of recoil which will govern the mounting of a gun for double recoil.

For free recoil of the gun,

$$V = \frac{v\,p + k\,w}{M} \quad \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

Where V = velocity of recoil of gun if unchecked
v = muzzle velocity of projectile
p = weight of projectile
w = weight of powder charge
M = weight of gun.

For smokeless powder k may be taken at from 4000 to 4700. For double recoil the formulæ are:

$$A = P\cos\phi - R \quad \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

$$z = \frac{VAM}{PN + AM} \quad \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

$$y = \frac{x^2}{2g}\left(\frac{N}{A} + \frac{M+N}{R}\right) \quad \ldots\ldots\ldots\ldots [4]$$

$$x = \frac{Mv^2 - (M+N)x^2}{2gP} \quad \ldots\ldots\ldots\ldots\ldots [5]$$

where N = weight of carriage or car
P = resistance of gun recoil system
R = resistance of carriage recoil system
A = accelerating force acting on carriage
ϕ = angle of elevation of gun
x = velocity of combined recoil
y = distance carriage recoils
z = distance gun recoils on its slide.

When a gun is fired, the gun and projectile move in opposite directions, in accordance with Newton's third law of motion, their relative velocities being inversely as their masses. We have also to take into consideration the effect of the powder. The gases leave the gun at a velocity much higher than the projectile. All problems in gun recoil begin with the theoretic velocity of free recoil.

Formula [1] is used to find the value of V, and k is a constant which has to be determined for each kind of powder.

Formula [3] expresses the velocity of combined recoil, that is, the velocity reached when the gun and carriage are moving together.

The other formulæ are for determining the length of the recoil of the carriage when checked by a known resistance and the length of recoil of the gun in its slide. They are not accurate, as they are based upon the supposition that the resistances are constant, but they give results sufficiently accurate for preliminary calculation.

As applied to the problem of mounting guns upon railroad cars in accordance with the system of double recoil, just explained, the formulæ are used as follows:

The resistance of the first recoil system P must be such that when the gun is fired at the highest allowable elevation, the vertical component of the reactive force will be within the bearing capacity of the car and roadbed. The resistance may be made great, for the reason that the car may be solidly blocked upon the road, and will withstand a considerable vertical load. A is the horizontal component of the force P,

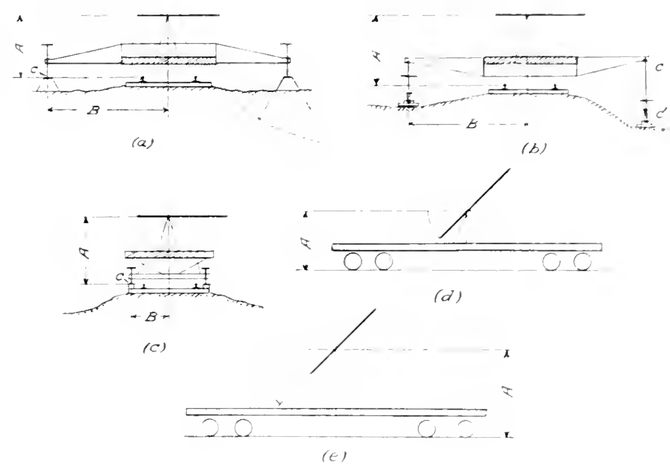


Fig. 5 Diagrams Showing Methods of Stabilizing

which tends to impart motion to the carriage and is found by Formula [2].

It is obvious that the resistance R must not be great. It must be so small that it will neither overturn the car nor shift the roadbed or other anchorage. It appears to me to be easier to provide a long horizontal recoil than a special anchorage.

Having determined these conditions, we find that after the gun is fired the velocity of the gun recoil is checked and a certain velocity is imparted to the carriage. The force P being great as compared with R, a point is soon reached when the gun and carriage are moving with equal velocity. From this point they may be treated, for practical purposes, as a single mass in motion. The gun will, of course, have some further motion on its slide, but this will be negligible as compared with the long horizontal recoil of the carriage.

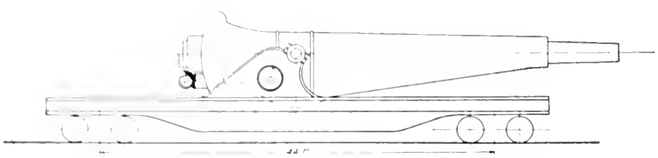
The weights of the car, gun and carriage being known, and the values of P and R determined with reference to conditions of strength and stability, the length of horizontal recoil for which allowance must be made is easily determined by Formula [4], which gives the value of y.

It has been proposed to mount heavy naval guns upon specially designed cars, and to provide at suitable points concrete foundations with locking devices, to engage the coöperating members on the cars, thus providing stable bases from which to fire the guns. The objection to the system is the initial cost and the difficulties met in securing the sites for the perma-

ment foundations and in maintaining them; also the fact that these sites will be mapped and known to the enemy.

Another system contemplates firing guns from a car moving on a curved track. The gun has a slight traverse on the car, but the main traverse in azimuth is secured by moving the car on the track. The gun being fired, the car recoils along the track. This is very objectionable for the reason that the gun has to be re-aimed after every shot. Thus you lose the advantage of a good shot. I do not think the system would be of value against a moving target.

Fig. 6 shows a gun of rather peculiar design mounted upon a railway car the trucks of which are arranged so that they can be completely turned under the car. This gun is fired from a track shown below. When being made ready for action, the front truck of the car is switched on to the curved track. The switch is then thrown so that the rear truck passes on to the straight part of the track. Traversing gears are provided



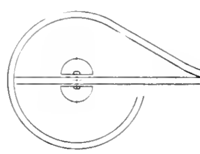


Fig. 6 Gun with Special Recoil Device Mounted on Railroad Car, and Circular Track for Traversing the Car

on the trucks so that the car may be worked forward until the rear truck is at the center of the system. Here an anchorage is provided of sufficient strength to sustain the reaction due to the recoil. The forward truck is traversed on the curved track about the center. The car is thus made to serve as a turntable. The gun fires from a fixed position. When the gun is elevated the breech swings down through an opening provided in the car platform. This arrangement brings the axis of the gun low for horizontal fire.

The laws of action and reaction are fixed, and it may be reasoned that no way can be found to lessen the shock of recoil excepting by making the recoil long. The case shown about this gun does, however, contain a mechanism—which, for obvious reasons, I am not free to explain—which does, to a great extent, lessen the shock of recoil, and the gun does not move back from the position shown when it is fired. The normal energy of recoil of a 14-in. gun is over 3,000,000 ft-lb. —enough to crush any ordinary railroad car or to lift it over a good-sized building. With the mechanism I have spoken of, the thrust upon the anchorage is only about 80,000 lb.

The first gun mounted upon a railway truck was mounted in the United States. This was done by the First Connecticut Artillery during the civil war. It was an old-time mortar, mounted on a truck. Five shots were fired from this gun before the truck collapsed. After that it was carried about on a flat car and fired from fixed platforms. Originally it was fired from a curved track.

[The paper from which this article is briefed was delivered prior to the entrance of the United States into the war. Although the work of mobile defense may for the time be set aside in consequence of the more pressing business of attacking the enemy, it is a work which must be carried out in the long run, and should be carried out so far as possible even during our present military exertion in order that no future emergency may find us unprepared.—The Author.]

War is a vast country-wide engineering enterprise. Theoretically speaking, an all-wise and powerful board of experts should determine where each man should be posted in the great war chain of fighters, for it is obvious that all specially trained men, and particularly all technically trained men, should keep at the posts where their training is needed. It was an inevitable mistake made by our allies at an earlier stage in the war which led many young physicians, engineers, mechanics and valuable specialists to rush as volunteers for the front. The technically trained men should be kept at their profession unless there happens to be a superfluity of them. The junior men in colleges, and particularly in technical or medical colleges, will probably serve their country better by working hard at their educational preparation than by abandoning their college work before their training is completed.—*The Electrical World.*

What is turning out to be a great storehouse of ammunition and explosives is being prepared by the Bethlehem Steel Company in New Jersey between Mays Landing, in Atlantic County, and Petersburgh, in Cape May County. This stretch of territory is more than forty miles long, stretching from north to south some five miles in width, on an average. It will afford ample space for testing good guns as well as for the storing of explosives and ammunition. More than 1000 men have been at work for a month in erecting the buildings, and the company is constructing its own railroad over the long stretch of territory, and the Government has given authority to build a new bridge across the Tuckahoe River. During the last ten days more than 150 freight carloads of ammunition have been brought into the grounds and stored. No strangers are admitted to the territory, which is surrounded by high barbed-wire fences, and the whole distance is patrolled by a company of soldiers to prevent trespassing. (Philadelphia *Public Ledger,* June 6, 1917, p. 7.)

Contracts have been let for the construction of a wind-tunnel building at Throop College of Technology, where researches in aerodynamics will be carried on. Here interesting and valuable experiments with airplanes will be conducted under the direction of Dr. H. Bateman, recently arrived in Pasadena from Johns Hopkins to take up this line of work, in which Throop College is one of the pioneers. The work takes on added significance from the recent announcement by the War Department of the plan to send an army of aviators abroad.

Dr. Bateman, who will have charge of the work, is a mathematical physicist, and his immediate investigations will relate to the stability of airplanes during flight, with which study the mathematical study relating to aeronautics is chiefly concerned. This aeronautics laboratory has been designed in consultation with Government experts in Washington and experts of the Curtiss Company in Buffalo, and the wind tunnel and apparatus to be used in connection with it represent the latest ideas in laboratory study of the science of aviation. (*Christian Science Monitor,* July 14, 1917, p. 8)

PROBLEMS IN WASTE DISPOSAL

By HENRY A. ALLEN, CHICAGO, ILL.

Member of the Society

Though the questions of disposal of wastes have been under consideration for many years, it is comparatively recently that such have been submitted to careful engineering study and analysis.

The main factors to be considered in the disposal of municipal wastes are sanitation and discommodity—the first as affecting the health of the individual and of the general public, the second as affecting the individual or public in the matters of inconvenience, unsightliness and offensiveness.

Cost. This factor is put last because it is assumed that any legislative body, appreciating the necessity of a function, will provide funds for the actuation of that function.

Often conveniences are demanded by individuals or the public, in utter disregard of the fact that such can not be had without commensurate expenditure of funds.

Economy in public works does not mean the apparent saving in moneys by the non-execution of a desired or required public improvement (so to speak, municipal deferred

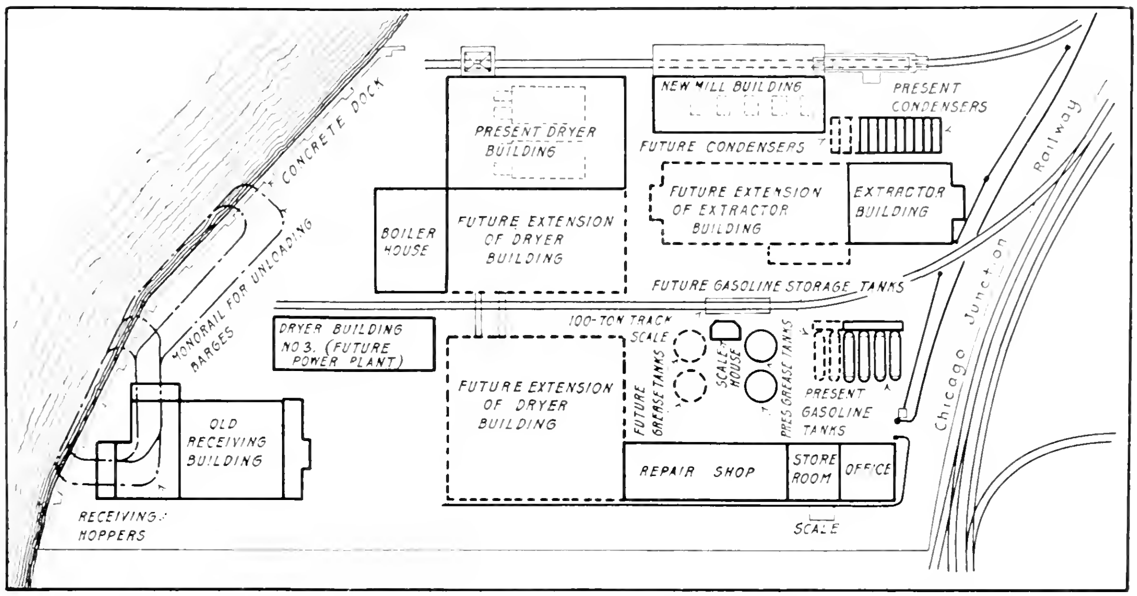

Fig. 1 Chicago Municipal Reduction Plant with Contemplated Extensions

In designing for a municipality, it is my opinion that the work should proceed along the following general divisions stated in the order of their importance:

FACTORS TO BE CONSIDERED IN WASTE DISPOSAL

Service. Service requires that the apparatus and structures shall at all times be able to perform the duties imposed. In the case of waste disposal it means at all times required ability to collect, transport and dispose of in a convenient and sanitary manner all wastes produced.

Discommodity. Discommodity or inconvenience relates to handling in a manner least disagreeable to, and entailing minimum effort on the part of, the individual or public.

Attractiveness. Attractiveness in structures is desirable as its tendency is to make less acute any actual or imaginary odium attached to a plant, whereas neglect tends to magnify such.

Economy of Operation. Economy of operation refers to the accomplishment of the work required in a most direct and inexpensive manner, having in view the obtaining of the greatest net monetary returns compatible with good sanitary and inoffensive operation.

maintenance), but making each dollar appropriated go farthest in the execution of a necessary or desired public improvement.

Obviously, it is to the engineering professions that the public must turn if it is desired to have solved, in a logical and practical manner, the various intricate problems of municipal waste disposal.

THE MUNICIPAL WASTE SITUATION IN CHICAGO

As the municipal waste situation in Chicago is typical of similar situations in many other cities of the United States, the following brief account may be instructive:

On August 30, 1906, the city of Chicago entered into a contract with the Chicago Reduction Co. for the disposal of the city's garbage.

The laws of the state of Illinois permit contracts to be entered into at any time of the year relative to the disposal of garbage, provided the duration of such does not exceed five years.

Owing to change in the system of disposal, at the end of two years a new contract was entered into for a period of five years ending August 31, 1913, which provided for a payment by the city of \$47,500 per annum to the contractor.

During this period it was claimed by the Chicago Reduction Co. that the city did not live up to its contract, and by the

Abstract of paper presented at a meeting of the Chicago Section of The American Society of Mechanical Engineers, January 19, 1917.

ity that the company did not operate its plant in a sanitary and inoffensive manner, as contemplated by its contract with the city.

Much dissatisfaction having arisen in regard to the manner of operation of the plant during the latter part of the term of contract, many individuals and civic associations began agitation for improvement of conditions, which finally resulted in an appraisal of the plant being ordered. A board of appraisers was appointed, consisting of H. M. Byllesby & Co., represented by Mr. Harold Almert, myself, appointed by His Honor the Mayor, City of Chicago, and Mr. Leonard Metcalf, selected by the two appraisers of the contending parties.

There was practically an agreement by all appraisers as to reproduction cost new; but a great difference in the question of physical depreciation, the city's appraiser estimating 41 per cent at the end of the five-year period, Byllesby & Co. 14 per cent, and the third appraiser a mean proportional of 24 per cent. The final fair values arrived at were approximately as follows:

City's appraiser	$226,000
Company's appraiser	762,000
Third appraiser	492,000

The company's appraiser agreed to the value of the third appraiser, but, as the city's appraiser considered this juggling, he withdrew.

After the disagreement of the appraisers, the city having

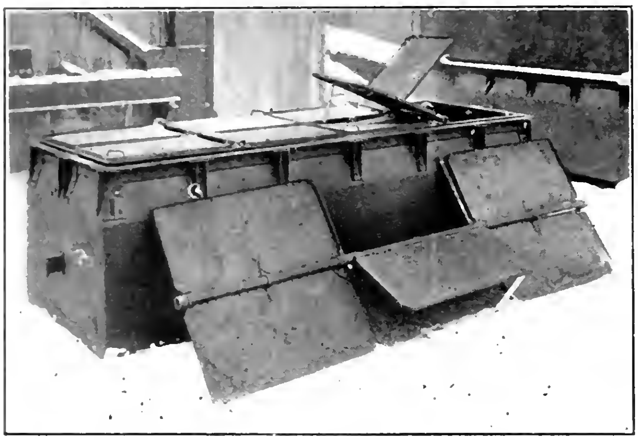

FIG. 2 GARBAGE BOX USED IN CHICAGO
(Length, 12 ft.; width, 4 ft.; depth, 32 in.)

no place to dispose of its garbage, I was asked to erect in two weeks' time a temporary garbage plant capable of handling a maximum of 500 tons a day until the city could make other arrangements. This work was accomplished, and, while not entirely inoffensive in operation, served well its purpose until the purchase of the plant of the Chicago Reduction Co. by the city.

Condemnation proceedings were commenced shortly after the appraisal of the property, but before they were completed, early in 1914, the company made a proposition to the city to sell its plant, including real estate, good will, etc., for the sum of $275,000. I previously advised against the purchase of this plant by the city, appreciating that rehabilitating an old plant and adding new structures while operating would result in high cost, and that when completed the plant would not be as well arranged and equipped as would be the case in a new plant constructed on a clear piece of ground.

Owing to the difficulty of securing a suitable location for a new plant, however, it was decided by the city to purchase the plant at the price offered—$275,000. In my original appraisal I estimated the worth of the plant to the city as the value of the land, plus salvage or scrap value, plus value of supplies on hand, plus an amount that may be termed the "value of temporary utility" or "availability for temporary use value," making a total of approximately $226,000. As this was in October and there were available approximately seven months before the hot weather of the following summer, I estimated the "temporary utility value of the plant" at approximately $80,000. When the offer from the Chicago Reduction Co. to sell was made, there remained practically but three months before the hot weather, too short a time to construct a new plant, hence I estimated an increase of $25,000 in "temporary utility value." As the cost to the city of condemnation proceedings would undoubtedly have been not less than $25,000, and in view of the fact that the property so obtained could be used for no other purpose than that for which condemned, I advised, all conditions being considered, that the company's offer be accepted.

It was during the bad weather of February 1914 that instructions were issued to start the work of rehabilitating the old reduction plant purchased from the Chicago Reduction Co. This necessitated the work of design and construction being carried on at the same time and working night and day. By June the plant was in condition to, and did, handle all the garbage of the city of Chicago in a practically inoffensive manner.

One of the greatest difficulties in disposal problems is the location of loading stations and plants, or, more strictly, the being permitted to locate such. While the citizens appreciate the necessity for disposal and attendant plants, they prefer such situated in their neighbors' back yards and offer strenuous objections when their own are under consideration. Hence, locations are too often required decided by political expediency rather than by good engineering judgment.

It is well to state here that the women of Chicago, through their various organizations, have played a most prominent part in bringing about the solution of the city's waste question, especially as regards garbage. These organizations are of invaluable assistance in educating householders to properly separate and take care of household wastes.

In my opinion, the city of Chicago has approached this great question in a most broad-minded and businesslike way, appropriating requisite funds to enable investigations, studies and experiments to be made, to the end that a foundation can be laid for the solutions of the various problems—not alone for today, but for years to come.

SELECTION OF A GARBAGE-COLLECTION UNIT

Having been selected chief of the technical staff, created on the recommendation of the city's Waste Commission, the necessary engineering and working forces, including waste investigators, were organized and systematic studies begun. At the same time, work on the design and construction of the municipal reduction plant, 95th Street incinerator, Bridewell crematory, and collecting and handling equipment was being carried on. To facilitate this work it seemed to me that somewhere along the line from the production of waste to the point of final disposal a unit should be selected. The most difficult phase of the entire problem is getting the garbage from the kitchen to the collecting unit.

It was for this reason that the garbage box was selected. The larger the capacity of this unit, other things being equal, the less the cost of collecting and handling. Study showed that

a six-cubic-yard box when filled became too heavy for a two-horse team, except on the very best of paved streets. As but 13 per cent of our alleys are paved and 62 per cent of our streets, this prohibited such a unit being used throughout the city. So, taking all in consideration, the unit adopted appears to be the most satisfactory. This consists of a box 12 ft. long, 4 ft. wide, and 32 in. high, as shown in Fig. 1.

Two such boxes can be loaded abreast, three in length and two vertically, making twelve boxes per specially designed railway car. One-half this number can be loaded on a specially designed street car. The net loads of garbage contained will be approximately 34 and 17 tons, respectively.

By adopting a standard collecting unit, hoisting equipment, including cranes, runways and slings; hauling equipment, including wagons and tractors; transporting equipment, including railway and electric cars, steam and tow barges, become standards for loading and disposal stations for various wastes.

The studies so far conducted indicate that it may be considered an axiom that that system handling an offensive substance which exposes the least or fewest surfaces to contact with such substance is the most sanitary, least offensive and, in general, commercially the best.

TABLE 1 COST OF GARBAGE DISPOSAL IN CHICAGO FOR FIVE YEARS PREVIOUS TO ACQUISITION OF GARBAGE PLANT BY THE CITY

Year Ended September 30	Amount Paid by City	Number of Tons Delivered	Cost Per Ton
1909	$47,500	89,957	$0 528
1910	47,500	97,087	0 489
1911	47,500	115,364	0.411
1912	47,500	118,225	0.401
1913	47,500	144,343	0.329
Totals.....	$237,500	564,976	$0 420

TABLE 2 AVERAGE NET COST PER TON TO THE CITY OF CHICAGO FOR HANDLING GARBAGE AT THE MUNICIPAL GARBAGE PLANT FROM TIME OF ACQUISITION TO SEPTEMBER 30, 1916

Year	Expense of Operation	Revenue	Net Cost of Operation	Garbage Tonnage Received	Net Cost Per Ton
1914......	$154,684.48	$ 96,585.06	$ 58,099.42	75,599¾	$0.768
1915......	278,570.35	183,196.83	95,373.52	150,874¾	0.632
1916......	432,721.86	410,512.28[1]	22,209.58	137,920½	0.161
Totals..	$865,976.69	$690,294.17	$175,682.52	364,395	$0.482

[1] During the year 1916 the extractor plant was in operation but from the first of June, and the mill house was not in full operation until the latter part of June. From January 1 to the time of starting the extractor plant, the city received only $3.27 a ton for commercially dried garbage, which is green garbage dried down to 10 per cent moisture.

The capacity of the old mill house was not sufficient to handle all garbage degreased, necessitating the storage of approximately 14,000 tons on the property north of the plant, thereby greatly increasing the cost of production of tankage.

TABLE 3 ESTIMATED PROFIT IN HANDLING GARBAGE AT THE CHICAGO MUNICIPAL PLANT DURING 1917

Cost of Operation	Revenue[1]	Net Revenue	Garbage Tonnage	Net Profit Per Ton
$477,000	$603,000	$126,000	145,000	$0.869

[1] Price of grease taken at 5 cents per pound and tankage at $5.00 per ton, both figures much below the present market prices.

COST FIGURES ON GARBAGE DISPOSAL

It is entirely feasible to construct a reduction plant or an incinerator to operate in a sanitary and inoffensive manner. To lay down a fixed set of rules, however, is not permissible, as the waste problems of each city must be considered as separate and distinct. Generally it costs money to incinerate, whereas money can be made by reduction, as will be seen from Tables 1 to 3.

SYSTEMS OF GARBAGE REDUCTION

Briefly, the following may be considered the present methods or systems of garbage reduction: Cooking process (Arnold and Edgerton), Cobwell system, chemical process, and drying process (Mertz and Simons).

In the cooking process the raw garbage is fed into large tanks called digesters, holding several tons of garbage each. These tanks are then closed and the contents subjected for several hours directly to a steam pressure varying between 40 and 80 lb. per sq. in., the tendency being to break down the cellular structures by boiling.

When the digestion is completed the emulsion of grease and tank liquors is drawn off. The solid matter generally is fed to a press where the main portion of the entrained oil and liquors is forced out, leaving a tankage containing 40 to 50 per cent of moisture. The tank liquors and grease obtained from the cooking and pressing process are passed through a series of settling tanks or basins in which the grease is separated gravimetrically and drawn off or skimmed from the top.

The tank liquors, which contain considerable fertilizer value, are treated in a multiple-effect evaporator to thicken before mixing with the degreased tankage.

The tankage after pressing is properly dried and subjected in a percolator to the action of a grease solvent which absorbs the remaining grease. The saturated solvent is distilled off and condensed, leaving the grease, the solvent being ready to use again. The degreased tankage and liquor, called "stickwater," are mixed, dried, milled and shipped.

There are several successful reduction plants employing this process, among them being the municipally owned and operated plant of the city of Columbus, Ohio, and privately operated plants at Pittsburgh and Philadelphia.

In the Cobwell system the green garbage is fed into a tub-shaped digester tank of several tons capacity, provided with a steam jacket or interior heating coils, and subjected to the direct action of a grease solvent at a temperature under 200 deg. fahr. Dehydration takes place for several hours, during which time the vapors are drawn off and condensed. These vapors consist principally of moisture and a portion of entrained solvent. After condensation the solvent is separated from the water and is ready for use again, the water generally being wasted.

During this operation a large proportion of the grease is dissolved in the solvent and the cellular structures for the most part broken down. The saturated solvent is then drawn off.

The tankage remaining in the digester is subjected to one or more washings of grease solvent, for the purpose of obtaining the greatest permissible amount of grease. The solvent with the dissolved grease is then drawn off and live steam introduced, as in the case of most percolator processes, to drive off as much of the remaining solvent as possible, to minimize loss. The tankage is then subjected to drying under vacuum by heat supplied from the steam jacket or coils.

When the moisture content has been reduced to less than 10 per cent, the contained tankage is removed, ground, screened and shipped.

It will be noted in this process that a large portion of the reduction is done in the one tank or digester.

Some of the latest municipal installations employ this system, among which are those in New Bedford and Los Angeles. The city of New York is endeavoring to build a plant, equipped with this process, of 2000 tons capacity of green garbage per 24 hours, estimated to cost approximately two and one-half million dollars. New York is having the common difficulty of securing a suitable location for the plant, owing to the objection of property owners near sites deemed suitable.

The chemical process proposed by Dr. Hirsch has not been demonstrated with the required exactitude to enable competent engineering judgment to be passed upon it. It consists of a treatment tank containing several tons of green garbage, the garbage being subjected to the action of certain chemicals which convert the cellulose into dextrin, or dextrose, depending upon the temperature employed and the time. Personally, I have great hope that such a system may be evolved.

Dr. Morgan claims to have a process by which he produces alcohol directly from garbage. The experiments so far made by him have not yet, I am informed, been sufficiently conclusive to enable an engineering report to be made.

In the three systems above described it will be noted that the green garbage is fed into tanks, which are then closed and the contents exposed to treatment.

GARBAGE-REDUCTION PROCESS USED IN CHICAGO

The fourth process mentioned is the dryer process and is the system in use at the municipal reduction plant in Chicago. In this process the garbage is generally first run through a crusher to smash open cans of condemned foodstuffs and to break up other large material to permit of more efficient drying. The material from the crusher is then fed into dryers, its moisture content being reduced to 10 per cent or less. From the dryers it is fed into percolators where it is subjected to the action of a grease solvent. The grease-saturated solvent is then drawn off and the solvent distilled off and condensed for repeated use, the grease being treated and stored ready for shipment. Steam is then turned on to drive off any residual solvent, after which the tankage, which contains about 26 per cent moisture, is withdrawn and then put through final dryers and dried to about 6 to 8 per cent moisture. It is then screened, milled and screened and stored ready for shipment.

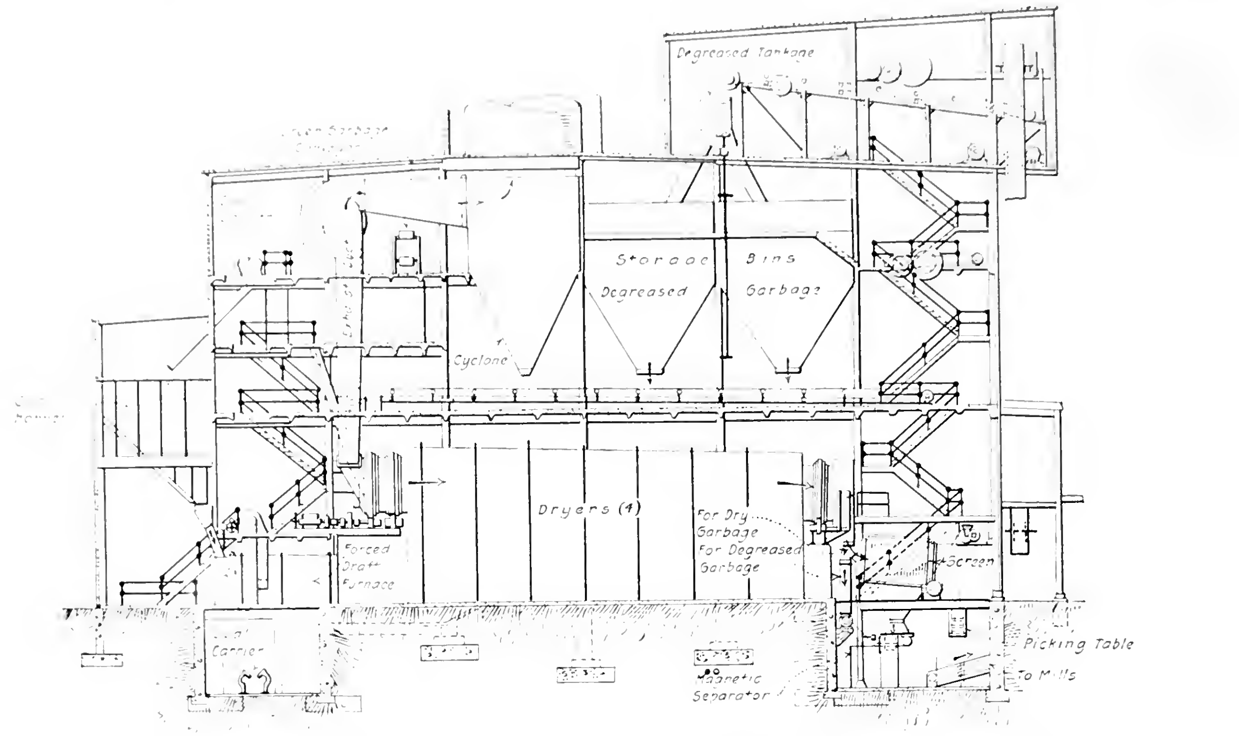

FIG. 3 LONGITUDINAL SECTION OF DRYER BUILDING, CHICAGO MUNICIPAL REDUCTION PLANT

This system was one of the first employed, but in most cases has been replaced by the cooking process or its latest modification—the Cobwell system. My investigation convinced me that one great cause of offense at the plant of the Chicago Reduction Co. was due to the use of direct-heat dryers and the consequent burning or carbonizing of certain greases and materials such as hair and flesh. This scorching action not only was the cause of offense, but also, I believed, the cause of loss in the amount and value of the by-products. The result was the installation of the more costly direct-indirect-heat dryers.

As predicted, when using the indirect-heat dryers not only has the necessity for scrubbing practically been eliminated, but the tankage and grease produced are better, with consequent increased values. The garbage is dried from 75 per cent moisture to 10 per cent or less in one cylinder.

The principal aim in designing this plant was to eliminate offense; therefore, not being content with the results thus attained, I thought it advisable to provide each dryer with a petticoat stack. This stack permits commingling of outside air with the gases escaping from the dryer, therefore cooling and throwing down a certain amount of moisture (which carries with it considerable very fine suspended matter) and in addition causing dilution.

The stacks are provided with suitable sprays, for use in case of any possible emergency due to delayed collection in hot weather or accidental fire or overloading. It will be noted that each dryer is arranged in the newly designed dryer building as a practically complete unit, having its own cyclone and petticoat stack.

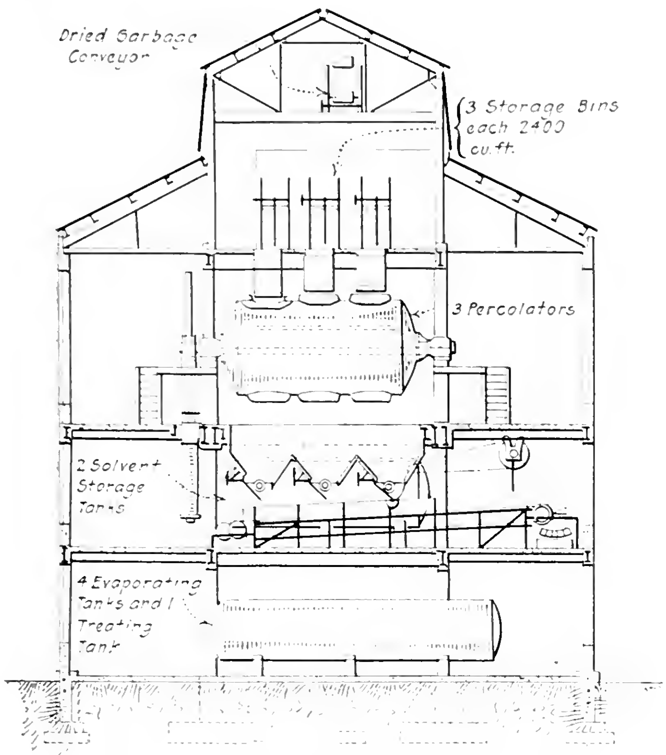

FIG. 4 CROSS-SECTION OF EXTRACTOR BUILDING

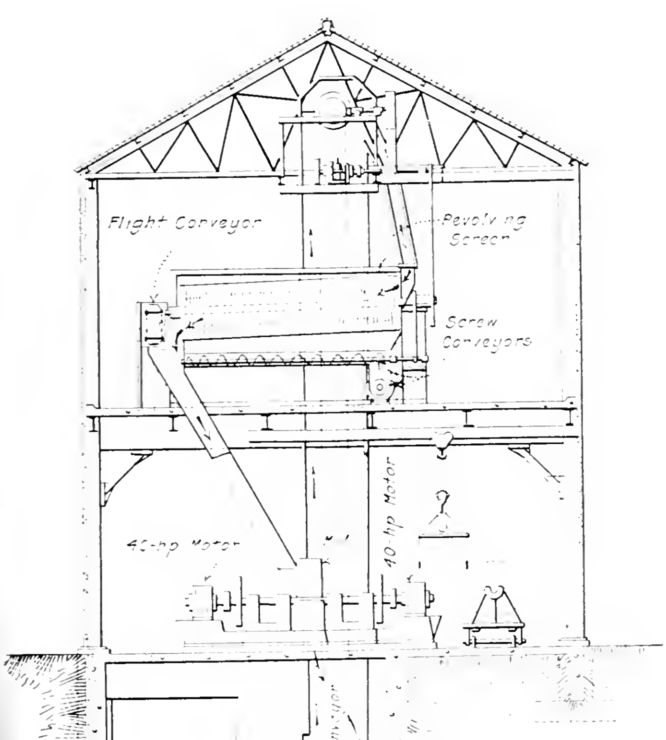

FIG. 5 CROSS-SECTION OF MILL BUILDING

BY-PRODUCTS FROM GARBAGE

An interesting as well as an economically important phase of the garbage-disposal situation are the many products derivable and derived from garbage, as indicated in Table 4. The kind and number of by-products produced, however, are matters to be determined by commercial expediency.

TABLE 4 PRODUCTS DERIVABLE AND DERIVED FROM GARBAGE

- Garbage..
  - Moisture plus Volatile (75%)....
    - Ethyl alcohol
    - Methyl alcohol
    - Formic acid
    - Acetic acid
    - Citric acid
    - Malic acid
    - Essential oils
  - Solids (25%)..
    - Garbage Grease
      - Glycerine.....
        - Nitroglycerine
        - Soaps
        - Toilet articles
        - Confectionery
      - Stearic acid...
        - Candles
        - Soaps
        - Fluxes
      - Red oil.......
        - Automobile industry
        - Liquoring fat
        - Sulphonated oil
    - Tankage.......
      - Carbohydrates
        - Starches
        - Sugars
        - Gums
        - Dextrine
        - Alcohol
      - Proteins......
        - Stick
        - Ammonium sulphate
      - Inorganic salts
        - Potassium sulphate and other potassium salts
        - Acid phosphate
        - Bone phosphate of lime
      - Rags.......... Paper pulp
      - Tin cans......
        - Tin
        - Iron scrap
      - Miscellaneous.
        - Glass, crockery, metal (other than tin cans) sand, ashes and rubbish

I estimate the amount of garbage that will be delivered to the plant during the year 1917 at not less than 150,000 tons, from which should be obtained not less than 8,000,000 lb. of grease and 30,000 tons of tankage. The city of Chicago at present has a contract for the purchase of garbage grease at a price of 7.29 cents per lb. on a basis of 3 per cent unsaponifiable. total impurities not to exceed 6 per cent. The city has a contract for the purchase of garbage tankage at the sum of \$4.16 per ton. The price received for the grease is high. but that received for tankage is low. the present market value of garbage tankage exceeding \$7 per ton.

In the July issue of the *Proceedings of the Engineers' Club of Philadelphia,* D. Robert Yarnall and G. A. Binz review recent development in V-notch weir measurement. concluding with a description of an elaborate test of a standard Lea meter made at the University of Pennsylvania. The paper is abstracted from the proceedings of the meeting of the Philadelphia Section of the Am.Soc.M.E.. April 24. 1917.

COMBINED STRESSES

By A. Lewis Jenkins, Cincinnati, O.

Member of the Society

In the past few years much has been written regarding the applications of the formulæ for combined stresses. The discussions consist of theoretical and experimental analyses of the stress relations resulting from complexed loadings which produce more than one kind of simple stress, such as combined shear and tension; and most of these are endeavors to prove that the designer should base his calculations on the maximum existing shear stress regardless of the relative strengths of the materials in tension compression and shear.

This popularity and stimulated interest in the subject of combined stresses was induced by Guest, who in 1900 published the results of his tests on the strengths of soft steel, copper and brass tubing when subjected to bending and twisting. The main conclusion drawn from the results of these experiments was that they were in accordance with the previously established fact that soft steel and most ductile materials are weaker in shear than in tension. Recently several writers have extensively advocated the use of the maximum-shear-stress hypothesis until they have reached the limit of having suggested its application in the design of cast-iron members! One of the most recent handbooks for designers gives only Guest's formula for the design of shafting subjected to combined bending and twisting, without mentioning the fact that it is absurd to use it for anything but a soft, ductile material.

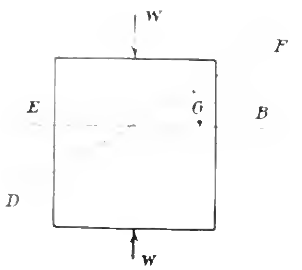

Fig. 1 Bar Subjected to Compressive Load

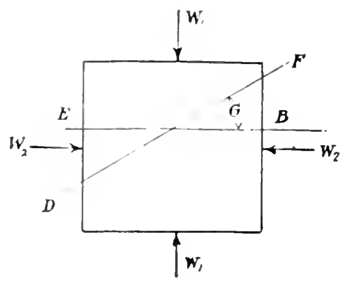

Fig. 2 Bar Subjected to Two Compressive Loads

There are six possible hypotheses upon which a formula for combined normal and shearing stresses may be based, namely, the maximum apparent and the maximum true or equivalent stresses in tension, compression and shear. Of these only the maximum apparent stresses in tension and shear and the equivalent tensile stress have been generally proposed for the design of shafts. Guest's formula is evidently not based on the apparent maximum shear stress as some writers have assumed.

Apparent and Equivalent Stresses Due to Loads That Produce Simple Tension and Compression Directly

Apparent Stresses in Normal and Oblique Planes. The bar shown in Fig. 1 is subjected to a compressive load W, and the simple compressive unit stress on the section EB is $C = W/A$ where A is the area of the cross-section through EB.

The area of the cross-section through DF, inclined at an angle G with EB, is $A/\cos G$; and the force normal to the plane DF is $W \cos G$; hence the apparent compressive unit stress acting normal to DF is

$$C' = \frac{W \cos G}{A/\cos G} = \frac{W \cos^2 G}{A} = C \cos^2 G$$

The component of W acting parallel to DF is $W \sin G$; hence, the apparent tangential or shear unit stress along DF is

$$S' = \frac{W \sin G}{A/\cos G} = \frac{W \sin G \times \cos G}{A} = \frac{C \sin 2G}{2}$$

The value of S' is a maximum when $G = 45$ deg., which means that the maximum apparent shear stress is along the plane making 45 deg. with the direction of the load and is equal to

$$S' = \frac{C}{2} = \frac{W}{2A} \qquad [1]$$

This indicates that the shear stress in a cast-iron cube is roughly equal to half the compressive stress when failure occurs.

The bar shown in Fig. 2 is subjected to two compressive loads W_1 and W_2 acting at right angles. Denoting the simple compresses unit stresses by C_1 and C_2 respectively, the apparent compressive unit stress on the plane DF is equal to

$$C' = C_1 \cos^2 G + C_2 \sin^2 G \qquad [2]$$

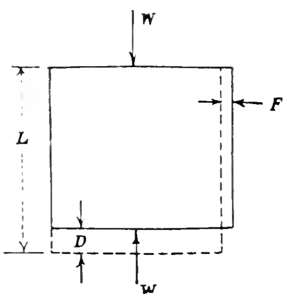

Fig. 3 Deformation of Loaded Bar

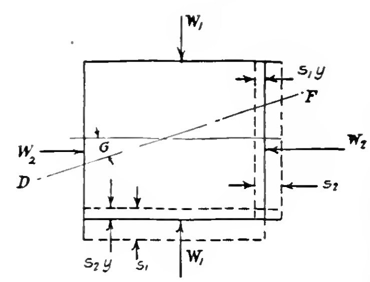

Fig. 4 Direct Compressive Unit Strain on Bar

and the apparent unit shear stress on DF is

$$S' = \frac{C_1}{2} \sin 2G - \frac{C_2}{2} \sin 2G$$

which is a maximum when $G = 45$ deg. and equal to

$$S' = \tfrac{1}{2}(C_1 - C_2) \qquad [3]$$

If W_1 and W_2 were reversed, they would produce tension instead of compression, and the apparent tensile unit stress on DF would be

$$T' = T_1 \cos^2 G + T_2 \sin^2 G$$

where $T_1 = W_1/A_1$ and $T_2 = W_2/A_2$. The maximum apparent shearing unit stress is a maximum when $G = 45$ deg. and is equal to

$$S' = \tfrac{1}{2}(T_1 - T_2)$$

If W_1 produced direct compression and W_2 direct tension, the apparent unit stresses would be

Presented at a meeting of the Cincinnati Section of The American Society of Mechanical Engineers, February 15, 1917.

$$C' = C_1 \cos^2 G - T_2 \sin^2 G$$
$$T' = T_2 \sin^2 G - C_1 \cos^2 G$$

and the maximum apparent shearing stress is

$$S' = \tfrac{1}{2}(C_1 + T_2).$$

It is seen from equation [2] that the greatest apparent compressive unit stress for the loading shown in Fig. 2 is either $C_1 = W_1/A_1$ or $C_2 = W_2/A_2$, depending upon the relative values of the loads and respective areas, the compressive stress normal to W_1 being independent of the load W_2 or the unit stress C_2.

Equivalent Stresses in Normal and Oblique Planes. The above method of determining the effect of combined stresses employs the ordinary methods of statics, and the results are known as apparent stresses. The method is based on the conception that unit stress is an internal resisting force acting on a unit area, and is found by dividing the load by the area.

A better conception of stress assumes that it is that property of a material which resists deformation of strain, and its intensity is measured by the product, Es, where E is the modulus of elasticity and s the unit strain or deformation produced in a unit of length.

In Fig. 3 the load W deforms the bar of unit area an amount equal to D and the unit deformation in the direction of W is $s = D/L$, where L is the length of the bar, and the unit compressive stress is $C = Es$.

Although there is a slight decrease in the volume in this case, due to the load W, the lateral dimension, which is equal to unity, is increased an amount equal to F. The ratio $F/(D/L) = F/s = y$ for a unit block is a constant for a given material, and is known as Poisson's ratio of lateral contraction. For any size block having a lateral dimension in the direction of F equal to L', then $y = (F/L') \div (D/L)$.

In Fig. 4, W_1 produces a direct compressive unit strain in its direction equal to $s_1 = C_1/E$ and a lateral unit strain (extension) equal to $s_1 y$.

The total unit strain in the direction of W_1 is

$$s_1 - s_2 y = \frac{C_1}{E} - \frac{C_2 y}{E}$$

The equivalent stress, or the single simple stress that will produce an equivalent strain in the direction of W_1 equal to that actually produced in that direction by the combined action of W_1 and W_2, is C_{e_1}. Hence

$$\frac{C_{e_1}}{E} = \frac{C_1}{E} - \frac{C_2 y}{E}$$

and $C_{e_1} = C_1 - C_2 y$.

Similarly the equivalent stress in the direction of W_2 is

$$C_{e_2} = C_2 - C_1 y$$

The equivalent compressive stress on the section DF is

$$C_e = C_{e_1} \cos^2 G + C_{e_2} \sin^2 G$$

and the maximum equivalent shear stress is

$$S_e = \tfrac{1}{2}(C_{e_1} - C_{e_2}) = \tfrac{1}{2}(C_{e_1} - C_{e_2} y - C_{e_1} - C_{e_2} y) =$$
$$\frac{1+y}{2}(C_1 - C_2) \ldots\ldots\ldots\ldots\ldots\ldots [4]$$

In general, the equivalent normal stresses (compression and tension), produced by simple compressive and tensile stresses acting in three directions perpendicular to one another, as shown in Fig. 5, are when all are tension.

$$T_{e_1} = T_1 - T_2 y - T_3 y$$
$$T_{e_2} = T_2 - T_1 y - T_3 y$$
$$T_{e_3} = T_3 - T_1 y - T_2 y$$

If any of the stresses should be compression instead of tension, its sign in the above equations should be changed.

The equivalent shearing stresses are:

$S_e = \tfrac{1}{2}(T_{e_1} - T_{e_2})$ in the plane of S_1 and S_2

$S_e = \tfrac{1}{2}(T_{e_2} - T_{e_3})$ in the plane of S_2 and S_3, etc.

MAXIMUM APPARENT AND EQUIVALENT STRESSES DUE TO COMBINED NORMAL AND SHEAR STRESSES

In machine construction many parts are required to resist both a single normal stress (tension or compression) and a simple shear stress. Cases where a machine element is subjected to more than one normal stress, together with one or more shear stresses, are quite rare; but there are many examples of a single normal stress being combined with a single shear stress, as in shafts being subjected to bending and twisting, propeller shafts, webs of beams, girders and machine frames, lathe beds, planer and boring-mill rails, spindles of milling machines, drilling machines and saws, bolts, screws for transmitting power, and numerous other machine parts.

Let the rectangle in Fig. 6 represent a small elementary area subjected to both a simple tensile stress T and a simple shear stress S, such as exists on the tension side of a shaft subjected to bending and twisting or in the web of a beam subjected to bending. On the compression side of a shaft or beam the normal stress is compression, or negative, and is denoted by C as shown in Fig. 7.

The normal stresses T and C may be produced by loads causing tension, compression or by any of their combinations, and

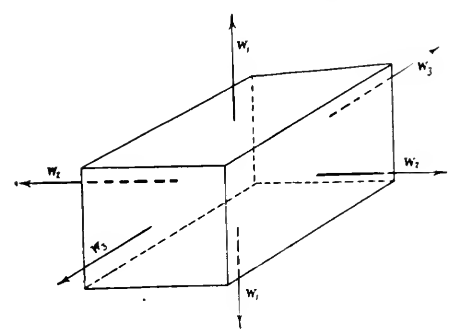

FIG. 5 LOADS IN THREE DIRECTIONS

the shear stress S may be produced by torsion or any other shearing action, such as vertical and horizontal shear in beams.

There are two ways in which the combined effect of these simple stresses may be expressed, namely,

1 By employing the ordinary methods of statics, in which case the results are known as apparent stresses

2 By applying the elastic theory, which states that the stress depends entirely upon the deformation or strain in the body. The results of this method, which is merely a refinement of the other, are called equivalent stresses.

The derivation of the formulæ for finding these stresses may be found in most textbooks on the strength of materials.

Maximum Apparent Normal Stresses. By resolving the stresses T, C and S perpendicular and parallel to any line such as AB in Fig. 6, the apparent shear stress along AB and the apparent compressive stress perpendicular to it may be found. Similarly, the tensile stress on FD may be found. When $\tan 2G = -2S/T$, the normal stresses are a maximum, which gives for the maximum apparent tensile stress

$$T' = \frac{T}{2} + \frac{1}{2}\sqrt{4S^2 + T^2} \ldots\ldots\ldots\ldots [5]$$

and for the maximum apparent compressive stress acting at right angles to it

$$C' = \frac{T}{2} - \frac{1}{2}\sqrt{4S^2 + T^2} \ldots\ldots\ldots\ldots [6]$$

Similarly, in Fig. 7 the maximum apparent tensile stress is

$$T' = \frac{C}{2} - \frac{1}{2}\sqrt{4S^2 + T^2} \ldots\ldots\ldots\ldots [7]$$

and the maximum apparent compressive stress is

$$C'' = \frac{C}{2} + \frac{1}{2}\sqrt{4S^2 + T^2} \dots\dots\dots\dots\dots [8]$$

From these equations it is seen that if a body is subjected to both a simple tension and a simple shear stress, the maximum apparent tensile stress is greater than the maximum apparent compressive stress by an amount equal to

$$T'' - C'' = \sqrt{4S^2 + T^2}.$$

In the case of a circular shaft subjected to bending and twisting, the stresses due to bending are T on the tension side and C on the compression side, and since these are numerically equal, the values of T' and C' are also equal.

Rankine held that the yielding of a material subjected to combined stresses depends entirely upon the maximum apparent normal stress, and was independent of the apparent shear and other stresses which may act at right angles to it. He also made no distinction as to the relative strengths of material in simple tension, compression and shear.

Maximum Apparent Shear Stress. The apparent shear

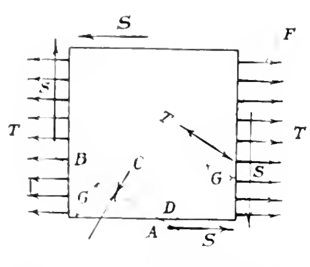

FIG. 6 SMALL ELEMENTARY AREA IN SIMPLE TENSION AND SHEAR

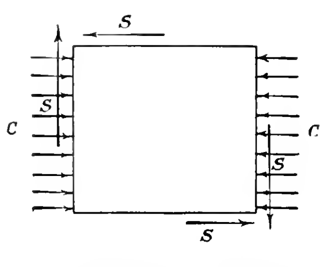

FIG. 7 NORMAL STRESS ON COMPRESSIVE SIDE

stress acting along AB in Fig. 6 becomes a maximum when $\cot G = 2S/T$ and is equal to

$$S' = \tfrac{1}{2}\sqrt{4S^2 + T^2} \dots\dots\dots\dots\dots [9]$$

and for Fig. 7

$$S' = -\tfrac{1}{2}\sqrt{4S^2 + C^2} \dots\dots\dots\dots\dots [10]$$

These formulæ have recently become popular on account of some writers having suggested their use in preference to any others, and by so doing they have made the same claims for them as Rankine made for the maximum normal stress formulæ, and again the relative strength of the material has been neglected.

Maximum Equivalent Normal Stresses. Any point on the surface of an area subjected to the simple stresses T and S is acted upon by an apparent tensile and an apparent compressive stress having directions at right angles to each other. In the planes of maximum stress these stresses become T' and C' and they produce a deformation or strain equal to

$$\frac{T'}{E} - \frac{C'y}{E}$$

The equivalent stress, namely, that single tensile stress which would produce a deformation equal to that actually produced by T' and C' is

$$T_e = T' - C'y$$

and the equivalent compressive stress is

$$C_e = C' - T'y$$

By substituting the values of T' and C',

$$T_e = \frac{1-y}{2} T + \frac{1+y}{2}\sqrt{4S^2 + T^2} \dots\dots\dots [11]$$

and

$$C_e = \frac{1-y}{2} T - \frac{1+y}{2}\sqrt{4S^2 + T^2} \dots\dots\dots [12]$$

In Fig. 7 the equivalent tensile stress is

$$T_e = \frac{1-y}{2} C - \frac{1+y}{2}\sqrt{4S^2 + T^2} \dots\dots\dots [13]$$

and the equivalent compressive stress is

$$C_e = \frac{1-y}{2} C + \frac{1+y}{2}\sqrt{4S^2 + T^2} \dots\dots\dots [14]$$

It should be noted that according to equation [11], $T_e = (1+y)S$ when $T = 0$; and $T_e = T$ when $S = 0$.

The theory that these equations should be applied to problems in combined stresses is due to Saint Venant, and is based on the assumption that the yield point of a material does not depend upon the apparent stress or stresses in any given direction, but upon the deformation or strain. It is sometimes known as the "maximum strain theory." This theory also neglects the relative strengths of the material.

Equivalent Shear Stress. The equivalent shear stress is

$$S_e = \frac{1}{2}(T_e - C_e)$$

and by substituting for the case shown in Fig. 6, gives

$$S_e = \frac{1+y}{2}\sqrt{4S^2 + T^2} \dots\dots\dots\dots\dots [15]$$

and for Fig. 7,

$$S_e = -\frac{1+y}{2}\sqrt{4S^2 + C^2} \dots\dots\dots\dots\dots [16]$$

In equation [15] it should be noted that $S_e = (1+y)S$ when $T = 0$; and $S_e = \frac{(1+y)}{2}T$ when $S = 0$.

The quantity $1+y$ is the ratio of the modulus of elasticity in tension to the modulus of elasticity in shear (modulus of rigidity).

This indicates that the true stress in a circular shaft subjected to a torsional moment M_t, is

$$S_e = \frac{5.1\,M_t}{(1+y)D^3}$$

and the true shear produced by a direct or purely tension or compression load is

$$S_e = \frac{(1+y)}{2}T \text{ instead of } \tfrac{1}{2}T$$

and $C_e = \frac{(1+y)C}{2}$ instead of $\frac{1}{2}C$.

Although these formulæ are given in Merriman's Mechanics of Materials in the form $S_e = \frac{(T_e - C_e)}{2}$, they have not been mentioned in the numerous discussions on combined stresses occuring in engineering periodicals.

RELATIVE STRENGTHS OF MATERIALS

Hard or brittle steels and cast iron fail in tension when subjected to torsional load or a tension load, and in shear when subjected to compression. Soft steels and other ductile materials fail in shear when subjected to either a tension or compression load or a torsional moment.

A hard-steel or cast-iron beam of T cross-section will fail in tension even though the flange is on the tension side. It is practically impossible to design a cast-iron beam that will fail on the compression side, and if the facilities for testing the strengths of materials were limited to a bending test, not even a conception of the compressive resistance of cast iron could

be determined. Neither can the shearing strength of a rectangular or a round bar made of brittle steel be determined from a bending test, for the simple reason that the tensile stress reaches the ultimate strength of the material before either the compressive or shear stresses become ultimate.

A torsion test of a round bar is extensively used in determining the shearing strengths of materials because pure torsion produces a shear stress that is greater than the normal stresses. The apparent normal and equivalent stresses produced are at least equal to the shear stress, and if the material is stronger in shear than in tension, it will fail in tension along a helical surface making an angle of about 45 deg. with the surface of the bar. Such a test is by no means a measure of the shearing strength of a brittle material such as cast iron.

When a highly finished soft-steel bar is subjected to tension, a series of lines inclined to the axis at about 45 deg. are readily noticeable after the elastic limit has been reached. These are known as "Lüder's lines," and are in the direction of the maximum shear stress. They indicate that the elastic shearing resistance and not the elastic tensile stress determines the yield point. Soft-steel bars actually fail in shear with a cup-shaped fracture that is somewhat modified by the flow of the metal during contraction.

It is known that brittle materials do not suffer an appreciable lateral contraction before failing in tension. They are stronger in shear than in tension, and the yield point of a hardened-steel bar almost coincides with the ultimate strength, it being elastic under almost any load within its ultimate strength. These facts suggest that the yield point and elastic limit might be wholly dependent upon the shear and not upon the tension- or compression-resisting properties of the material. In the light of the present knowledge of the effect of hardening steels, it is entirely possible that the actual ultimate tensile stress is not increased by hardening and the apparent increase in tensile strength is caused by the increased shearing resistance due to the treatment.

In view of these facts, it seems quite probable that the tension test of a soft-steel bar does not reveal its true tensile strength, yield point or elastic limit with any greater degree of accuracy than a torsion test reveals the shearing strength of hard steel or cast iron. It would be very interesting to know the tensile strength of a bar loaded in such a way as to eliminate the shearing stresses and thereby forcing its failure to occur in tension.

The term *compressive strength* is merely used to denote the unit compressive stress in a body subjected to a compressive load when the shearing stresses and friction can no longer resist rupture.

It is easy to see that a bar may be ruptured in tension by the fractured surfaces separating normally or in shear by the fractured surfaces sliding upon each other, producing tangential separation; but in the case of a short bar of metal or stone subjected to compression, the direct effect of the load is to press the material together instead of producing separation.

Very soft materials, when subjected to compression, flow laterally and do not separate; whereas brittle materials fail in shear before they will flow, and some steels develop cracks parallel to the direction of the load after the material has suffered considerable lateral extension, showing that the separation is caused by tension. It is difficult to acquire an abstract conception of ultimate compressive strength, and no means are available by which even the elastic compressive strength may be shown to be dependent upon any property other than the elastic strength in shear.

SELECTION OF FORMULA FOR A GIVEN MATERIAL AND LOADING.

A body subjected to a complex loading will fail when the stress in any direction at any point reaches the ultimate resistance of the material in that direction at that point.

Conceive of a chain consisting of three or more elements of special design—one link so designed that the maximum stress is tension, another in which the compressive stress is much higher than the tension or shear, and the third element having its minimum resistance in shear. The links are so proportioned that a load on the chain will produce a tension, compression and shear stress in the respective links that is numerically the same for all. How would the chain fail? If made of cast iron it would fail in tension, of glass it would fail in compression, and of soft steel it would fail in shear. It is obviously absurd to say that such a chain constructed of hard steel or cast iron would fail in shear; yet that is in accord with the idea that some discussions on combined stresses were intended to convey.

According to Hancock, the numerical values of the stress at the yield point and at the elastic limit are practically equal. It has also been observed that a material usually fails ultimately in the same manner in which it first yields; hence the yield points or elastic strengths of a material may be used as a criterion of its relative ultimate strengths.

Let Q = yield point in shear
P = yield point in tension
F_s = factor of safety in shear = Q/S_e
F_t = factor of safety in tension = P/T_e

In order to have equal factors of safety against yielding in tension and shear

$$F_t = F_s \text{ and } \frac{F_t}{F_s} = 1$$

substituting,

$$\frac{P/T_e}{Q/S_e} = 1$$

$$\frac{P}{Q} = \frac{T_e}{S_e} = \frac{(1-y)\quad T/S}{(1+y)\sqrt{(4-T^2/S^2)}} + 1 \ldots\ldots\ldots [17]$$

If the right-hand side of this equation is greater than the left the factor of safety in tension is less than the factor of safety in shear, and yielding will occur first in tension; which shows that the equivalent-normal-stress formula should be used. If the left-hand member is the greater, yielding will occur first in shear; showing that the formula for equivalent shear stress should be used.

If the value for Q is obtained by a torsion test it is more accurate to use

$$\frac{P}{Q} = \frac{T_e}{S_e} = \frac{(1-y)\quad T/S}{\sqrt{4+T^2/S^2}} + 1 + y \ldots\ldots\ldots\ldots\ldots [18]$$

These formulæ are for determining whether a body made of a given material and subjected to a given shear and a given tensile stress is weaker in shear than in tension and enable the designer to select the proper formula.

Similar formulæ may be written for compression and shear or compression and tension.

FORMULAE FOR THE DESIGN OF SHAFTS SUBJECTED TO BENDING AND TWISTING

Let M_b = external bending moment
M_t = external twisting moment
M_{be} = equivalent bending moment which would produce the same normal stress as M_b and M_t

M_{te} = equivalent twisting moment that would produce the same shear stress as M_b and M_t

I = rectangular moment of inertia

J = polar moment of inertia

c = distance from the neutral axis to the extreme fiber, or radius of a round shaft

Z_r = rectangular modulus of section, I/c; for round section $D^3/10.2$

Z_p = polar modulus of section $J/c = 2I/c = D^3/5.1$ for round section

D = diameter of shaft

P = unit tensile stress at yield point

Q = unit shearing stress at yield point

T = working stress in tension

S = working stress in shear.

Then

$M_b = TI/c$ and $M_t = SJ/c$

Maximum Normal-Stress Theory. According to the maximum normal tress theory the stress producing yielding is

$$T' = \frac{T}{2} + \frac{1}{2}\sqrt{4S^2 + T^2} \quad \ldots\ldots\ldots\ldots [19]$$

By multiplying this equation through by I/c and remembering that $J/c = 2I/c$, it becomes

$$T'I/c = TI/2c + \frac{1}{2}\sqrt{S^2J^2/c^2 + T^2I^2/c^2}$$

by substitution, the equivalent bending moment is

$$M_{be} = \frac{1}{2}(M_b + \sqrt{M_b^2 + M_t^2}) \ldots\ldots\ldots [20]$$

and consequently the stress is

$$T = \frac{5.1}{D^3}(M_b + \sqrt{M_b^2 + M_t^2}) \ldots\ldots\ldots [21]$$

The form frequently given in text books is due to Rankine, who wrote it in terms of the equivalent twisting moment: namely:

$$M_{te} = M_b + \sqrt{M_b^2 + M_t^2} \ldots\ldots\ldots\ldots [22]$$

from which the shearing stress is

$$S' = \frac{5.1}{D^3}(M_b + \sqrt{M_b^2 + M_t^2}) \ldots\ldots\ldots [23]$$

which is the same value as given for the tensile stress above. This is due to the substitution of M_{te} for $T'J/c$ in the derivation of the latter formula. If the tensile stress at the yield point due to bending is the same as shearing stress at the yield point due to torsion, T' might be substituted for S'; but as a matter of fact, the ratio P/Q is not unity. The requirement for equal factors of safety in shear and in tension was found to be $T' = PS'/Q$. Hence, Rankine's equation should be written

$$M_{te} = \frac{Q}{2P}(M_b + \sqrt{M_b^2 + M_t^2}) \ldots\ldots\ldots [24]$$

for the general case.

Maximum-Strain or Maximum-Equivalent-Normal-Stress Theory. According to Saint Venant's theory the stress producing yielding is

$$T_e = \frac{(1-y)}{2}T + \frac{(1+y)}{2}\sqrt{4S^2 + T^2} \ldots\ldots\ldots\ldots [25]$$

By the same method used in the preceding case it is found that

$$M_{be} = \frac{(1-y)}{2}M_b + \frac{(1+y)}{2}\sqrt{M_b^2 + M_t^2} \ldots\ldots\ldots [26]$$

and

$$M_{te} = \frac{Q}{P}[(1-y)M_b + (1+y)\sqrt{M_b^2 + M_t^2}] \ldots\ldots [27]$$

The formula used by the French engineers is

$$M_{be} = 0.375\,M_b + 0.625\sqrt{M_b^2 + M_t^2} \ldots\ldots\ldots\ldots [28]$$

and was derived by Grashof, who used 0.25 for the value of y.

The formula due to Bach and much used in Germany is

$$M_{be} = 0.35\,M_b + 0.65\sqrt{M_b^2 + M_t^2} \ldots\ldots\ldots\ldots [29]$$

the value of y being taken equal to 0.3.

Maximum-Apparent-Shear-Stress Theory. It has been shown that the maximum apparent shear stress is

$$S' = \frac{1}{2}\sqrt{4S^2 + T^2} \ldots\ldots\ldots\ldots [30]$$

By multiplying through by J/c and substituting, it is found that

$$M_{te} = \sqrt{M_b^2 + M_t^2} \ldots\ldots\ldots\ldots [31]$$

and

$$M_{be} = \frac{P}{2Q}\sqrt{M_b^2 + M_t^2} \ldots\ldots\ldots\ldots [32]$$

Equivalent-Shear-Stress Theory. From the equation for equivalent shear stress

$$S_e = \frac{(1+y)}{2}\sqrt{4S^2 + T^2} \ldots\ldots\ldots [33]$$

The equivalent twisting and bending moments are

$$M_{te} = (1+y)\sqrt{M_b^2 + M_t^2} \ldots\ldots\ldots\ldots [34]$$

and

$$M_{be} = \frac{P}{2Q}(1+y)\sqrt{M_b^2 + M_t^2} \ldots\ldots\ldots\ldots [35]$$

Maximum Compressive Strength. The fact that practically all materials used in machine construction are equally as strong or stronger in compression than in shear or tension eliminates the compressive strength as a criterion in design. Glass has the distinction of having a greater resistance in tension than in compression and if its physical properties were definitely known it is quite probable that the maximum-compressive-stress theory would be found applicable.

Guest's Formula. The formula deduced by Guest from his experiments is written

$$M_{be} = \sqrt{M_b^2 + M_t^2} \ldots\ldots\ldots\ldots [36]$$

whereas the maximum apparent shear stress gives

$$M_{te} = \sqrt{M_b^2 + M_t^2}.$$

In order to determine the diameter of shaft the former is equated with $TD^3/32$ and the latter with $5D^3/16$, which causes Guest's formula to give a stress twice that of the maximum, apparent-shear-stress formula.

The expression given by Guest could be obtained from equation [32] if $P/Q = 2$ or from equation [35] when

$$P\frac{(1+y)}{2Q} = 1$$

By assuming $y = 0.3$ this expression reduces to $P/Q = 1.57$.

Guest did not give the values of P/Q and y for the materials used in his experiments. The values of P/Q given by Hancock[1] are as follows:

	P	Q	P/Q
Steel Tubing	21,000	10,500	2.000
Nickel Steel	76,500	38,000	2.013
Mild Carbon Steel	47,000	30,500	1.546
Steel (Scoble)	64,600	29,170	2.214
Carbon Steel	55,500	24,400	1.454
Rivet Steel	38,900	23,400	1.662
Nickel Steel	56,000	35,000	1.555
Steel Tubing	17,000	11,500	1.478
Steel Tubing	28,000	16,000	1.750
Steel Tubing	20,000	12,000	1.666

[1] Proceedings A.S.T.M., Vol. viii, 1908.

It is seen from the results in this table that the value of $P/Q = 1.54$ corresponds to that given for mild carbon steel; and the values for steel tubing, the material used by Guest, vary from 1.47 to 2.00. These results apparently favor the two shearing-stress theories about equally well; but by accepting the elastic theory it is preferable to assume that the value 1.54 is the proper one to use, which means that the equivalent-shear-stress theory is the more accurate of the two and should be used for soft or ductile materials. There is nothing in Guest's results to show which of these theories he used. His formula is empirical and the data on the elastic limits and ratios of lateral contraction are lacking.

Selection of Formula. For the design of shafts made of hard or brittle materials such as cast iron or hard steel the Grashof formula

$$M_{be} = \frac{3M_b}{8} + \frac{5}{8}\sqrt{M_b^2 + M_t^2}$$

should be used.

For the design of shafts made of soft or ductile materials such as very mild steels the equivalent-shear-stress formula

$$M_{te} = (1 + y)\sqrt{M_b^2 + M_t^2} = 1.3\sqrt{M_b^2 + M_t^2}$$

should be used.

When the equation

$$\frac{P}{Q} = \frac{(1 - y)\,M_b}{(1 + y)\sqrt{M_b^2 + M_t^2}} + 1$$

is satisfied both of the above equations give the same result and either may be used. When the right-hand side of the equation is the greater, use the equivalent-normal-stress formula, and when less use the equivalent-shear-stress formula.

CONCLUSION

The equivalent stresses are a refinement over the apparent stresses and both theoretical and experimental results show that the former is the more accurate. The equivalent-stress formulæ are written as follows:

Equivalent tensile stresses

$$T_e = \frac{(1 - y)}{2}\,T + \frac{(1 + y)}{2}\sqrt{4S^2 + T^2}$$

$$T_e = \frac{(1 - y)}{2}\,C - \frac{(1 + y)}{2}\sqrt{4S^2 + C^2}$$

Equivalent compressive stresses are

$$C_e = \frac{(1 - y)}{2}\,C + \frac{(1 + y)}{2}\sqrt{4S^2 + C^2}$$

$$C_e = \frac{(1 - y)}{2}\,T - \frac{(1 + y)}{2}\sqrt{4S^2 + T^2}$$

Equivalent shear stresses are

$$S_e = \frac{(1 + y)}{2}\sqrt{4S^2 + T^2}$$

$$S_e = \frac{(1 + y)}{2}\sqrt{4S^2 + C^2}$$

The tensile-stress formulae should be used when P/Q is less: and the shear-stress formulae should be used when P/Q is greater than

$$\frac{(1 - y)\,T}{(1 + y)\sqrt{4S^2 + T^2}} + 1$$

if the material fails in torsion with a helical-shaped fracture. the equivalent-normal-stress formula should be used, and if in torsion it fails in a plane perpendicular to the axis, the equivalent-shear-stress formula should be used.

If a material fails in tension with a decided cup-shaped fracture, the equivalent-shear-stress formula should be used; whereas failure perpendicular to the axis of the tension specimen indicates that the equivalent-normal-stress formula is preferable.

The Association of Iron and Steel Electrical Engineers will hold its eleventh annual convention at Philadelphia, Pa., Sept. 10-14, with headquarters at the Bellevue-Stratford Hotel. The day of Sept. 12 will be devoted entirely to a patriotic program, with addresses by army and navy engineers on vital subjects concerning our industries.

At Harvard University three prizes, amounting to $200, known as The Nelson Prizes in Plumbing, have just been awarded for the best papers on subjects having to do with the theory or practice of plumbing. A new contest similar to the one just completed but involving a larger sum of money is planned. to be offered this coming year. It is probable that a fellowship will be also offered by Harvard. and engineering graduates who have knowledge and ability to handle problems dealing with sanitation should be especially interested.

The annual convention of the American Institute of Electrical Engineers, which was to have been held at Hot Springs. Va., was postponed on account of many conditions arising from the war. and in its place a special two-day convention was held in the Engineering Societies Building, June 27 and 28.

Topics of the professional sessions included high-tension cables, high-tension insulators, use of electricity in mines, and economical combinations of water-power and steam plants. A paper on the last subject described a method for determining the economical limits in steam and water-power developments.

In his presidential address. President H. W. Buck pointed out that, although engineering has been one of the most important factors in the development of our civilization, nevertheless the engineer has had a difficult struggle to begin to attain the recognition due him. However, the particular training that the engineer acquires in the pursuit of his profession particularly fits him to fill every position in our political and economical affairs, and in the future he is destined to occupy more and more positions of public trust.

Mr. E. W. Rice, Jr., president-elect for the coming year, addressed the meeting on Modern Warfare a Question of Engineering. He said in substance that although it is important that we have an army at the front, the most effective work can be done in the shop and office at home by bending forth every effort toward supplying the army with all the modern appliances of warfare to make it most efficient, and not to wait for the miracle that will never appear. He expressed his belief that the submarine problem will be solved by the combined efforts of engineers and scientists, that we should build ships and the best kind of ships, and that all shipping should be used to the best advantage: that it is not so much a question of the number of ships as it is a case of keeping them in use, which means that our docks must be equipped by the most modern apparatus for loading and unloading the vessels so as to keep them in service.

C. O. Mailloux announced that recruiting for a corps of electrical engineers and electrical workers to go to France would soon begin, to build up the electrical systems in that country. This corps will be similar to the body of railway engineers that was recently organized in this country to build up the transportation systems in France.

CONTRIBUTED DISCUSSIONS OF SPRING MEETING PAPERS

SUBSEQUENT to the publication of the account of the Spring Meeting in the July issue of THE JOURNAL, five contributions have been received which should be appended to this account. Prof. R. Pohakoff, of the Technical Institute of Moscow, Russia, contributes a statement of the Technical Bureau of the Russian Artillery Commission in discussion of Mr. E. F. Walsh's paper on The Importance of Intelligent Inspection in Munitions Manufacture; also a more complete discussion of Mr. A. L. De Leeuw's paper on A Foundation for Machine Tool Design and Construction. Mr. Victor B. Phillips, author of the paper on Relation of Efficiency to Capacity in the Boiler Room, now in active service, forwards the closure to the discussion of his paper. Mr. Charles Meier replies to Mr. Carl G. Barth's discussion of his paper on Metal Planers and Methods of Production, and Mr. Barth answers Mr. Meier's reply.

DISCUSSION OF PAPER ON A FOUNDATION FOR MACHINE TOOL DESIGN AND CONSTRUCTION

TO THE EDITOR:

In Par. 32 of his paper, Mr. De Leeuw refers to a tool which he shows in his Fig. 4, mentioning that this tool broke down very soon after the surface of the hollow began to show scratches. I do not know what was the plan of the tool, whether it had a round edge or not, but the scratches might have been attributed to the following reason:

If you take the ordinary round-edge tool (Fig. 1) with the ordinary angles of front rake, side rake and clearance, you will find by a very simple mathematical analysis that when the front rake is less than the side rake—as it usually is—the cutting angle changes from point to point of the edge. I assume herewith that the chip and all its elements go off the bar at a right angle to the cutting edge at the respective point. It will have one value at the plane *ab* (i.e., at the plane of the front rake), a lesser value at the plane *bc* (side rake), and intermediate values at points *de*, etc.; and if you lay off the respective values of the cutting angles at the corresponding different points *a, d, e, c*, of the cutting edge, then these values would change like the curve a', d', m', c' (Fig. 2). In other words, the angles will first decrease, then go up a little, then decrease again until they reach the lesser value cc', corresponding to the plane *bc*. These angles, with an ordinary round-edge tool and the ordinary usually accepted angles of side and front rake, therefore change in a curve with some peak points in it.

If you will assume that the chip consists of elementary chips, each element going off the bar at right angles to the cutting edge, then these different elementary chips have to descend on inclined planes with changing angles, and necessarily one elementary chip is either retarded or accelerated in its downward movement by its adjoining chip; and this retardation or acceleration necessarily must create inner friction and cause the different scratches on the hollow of the tool, every single scratch being the mark left by the elementary chip.

If the scratch to which Mr. De Leeuw referred can be attributed to the reasons just cited, then, in my judgment, the following remedy could be suggested to avoid these scratches and prolong the life of the tool:

All the cutting angles must be equal at all points of the cutting edge, starting at the *ab* plane and terminating at the plane *bc*; and in order to achieve this end, the quadrant *adec* should not be a plane but a quadrant of a circle drilled out by a drill with its center point at *b* and having a radius *ab* equal to *bc* and its cylindrical body projecting in the line *adc*. In this way all the cutting angles would be equal all the way through from *a* to *c* just as in the case of a straight-edge tool.

Of course, this calls for another way of preparing the turning tool altogether, both with regard to machining and grinding, but this can be very easily arranged. In fact, I introduced such a tool in the Laboratory of Technology at the Technical Institute, Moscow, Russia, some two and a half years ago, and have also designed some grinding attachments to grind the hollow produced by the drill.

I started to make some experiments with a tool so designed, but had to discontinue them on account of being sent over to this country in connection with the war. I hope, however, to resume the experiments in the near future, and shall be glad to report to your Society the results obtained.

I also made some dynamometer tests with such a tool, but these tests are, too, in an unfinished condition as yet.

Referring to the circular tool of Mr. De Leeuw, Par. 35, I believe that he originated this tool about two and a half years ago. I do not know how much experimenting has been done with this tool in this country, but I may mention that as soon as I read about it in the *American Machinist*, where it was originally described, I prepared a tool along the same lines with the object of making some experiments, but, as already stated, I had to leave for the United States and therefore could not make them.

However, I published an article in a Russian technical magazine describing the construction of this tool, and, based upon this description, a few tools have been prepared in the Ijev Rifle Works, in the Ural mountains. When I visited these works in 1915 I was shown the results of their experiments, which proved to be very satisfactory, both with regard to speed and life of the tool. I have sent these facts to the Russian magazine, *Vestnik Ingenerov*, for publication.

Referring to Mr. De Leeuw's Suggested Lines of Experimentation, I fully agree with what the author says, but I can easily see some objections from the so-called practical viewpoint of shop men. Mr. De Leeuw suggests that these experiments should be made at low speeds, and whatever the results of such experiments should be, the ordinary shop man will probably say, "That's all right—it may be all right in theory, but how about the practical side, where the results of such experiments are quite different?" They will doubt if the results of such experiments can be fully applied to practice.

In connection with this I may mention that very few experimental data have been published along the line of cutting with fine cuts, although a little has been done.

Edward Herbert, of Manchester, England, has been working along such lines for some time, and has invented a special machine for taking very fine cuts from a hollow tube. He has published some of the results of his experiments and they are very interesting, especially with reference to the cut, as they show that a finishing tool fails quite differently from an ordinary roughing tool.

In the roughing cut, when you increase the speed, leaving all other conditions equal, the time of the endurance of the tool decreases, something like curve *ab*, Fig. 3, in which the

abscissæ represent the speed and the ordinates the endurance time. In the case of the finishing tool, however, the endurance curve is something like the curve *abcd*, Fig. 4, with some peaks in it, which means that when you increase the speed of the finishing cut the endurance time may increase up to a certain limit, and then will start to decrease with a further increase in

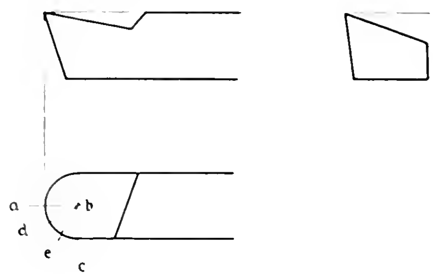

FIG. 1 ROUND-EDGE TOOL

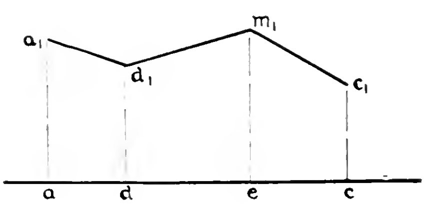

FIG. 2 VALUES OF CUTTING ANGLES

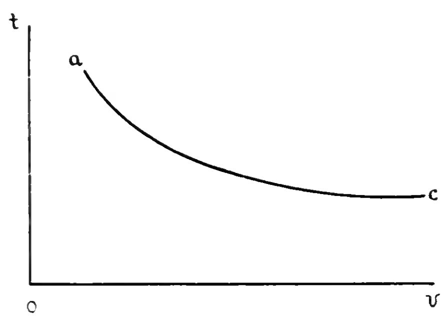

FIG. 3 ENDURANCE TIME OF TOOL IN ROUGHING CUT

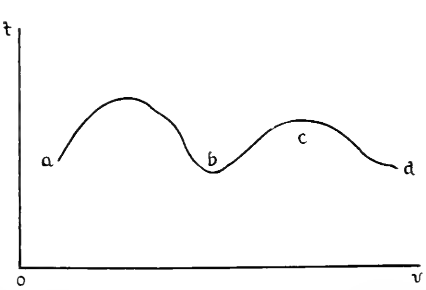

FIG. 4 ENDURANCE TIME OF TOOL IN FINISHING CUT

the cutting speed. If the cutting speed continues to increase, the endurance time may go up again. From this one can draw the conclusion that there is probably a certain speed which is the most profitable for working so far as endurance of the tool (and, as experiments show, also the appearance of the machined surface) is concerned.

When Mr. Herbert presented his paper on this subject some three or four years ago, he met with the same objections to which I have just referred, i.e., that these experiments may be of much theoretical value but are very doubtful so far as practical results are concerned.

In order to meet these objections to a certain extent, I made some experiments on finishing cuts, but in a quite practical way, and under conditions absolutely identical with those prevailing in ordinary shop practice. It would perhaps be out of place to go into too many details of these experiments at this time, especially as I have already presented them in a paper before the Institution of Mechanical Engineers, in Manchester, an extract of which was published in the *American Machinist* some ten months ago.

Suffice it here to say that these practical experiments fully confirmed the results of Mr. Herbert's experiments made under conditions different from shop practice.

Therefore, I can most assuredly say to shop men that practice and theory go hand in hand together, and if the theoretical experiments are conducted on the right lines, they are sure to yield valuable practical results.

R. POLIAKOFF.

New York, N. Y.

AUTHOR'S CLOSURE TO DISCUSSION OF PAPER ON RELATION OF EFFICIENCY TO CAPACITY IN THE BOILER ROOM

TO THE EDITOR:

In their discussions both Mr. Barrus and Mr. Reinicker are unwilling to attach any accuracy to tests of eight hours' duration. The author understands fully the validity of objections to eight-hour tests and the tests in question were conducted with these objections in mind. They could not have been conducted otherwise. As regards the degree of accuracy of the efficiencies obtained, it may be said that the closely accurate determination of efficiency was throughout of secondary importance. None of the data sought nor conclusions reached is impaired by an inaccuracy of, say, 3 per cent in the overall efficiency. The overall efficiency is the only quantity that the employment of the short test can bring into question. It will be noted that differences in efficiency by virtue of differences in fuel-bed thickness are far in excess of any possible inaccuracy in the values of efficiency. Furthermore, all other observations and the conclusions drawn therefrom are in no way subject to the criticism of the short duration. It is quite conceivable that the curvature or slope of some of the lines on the furnace and boiler unit operation charts may be appreciably in error. These charts were presented, however, to illustrate certain general principles, and are believed to be of sufficient accuracy to serve this purpose. The entire part of the paper relating to the boiler as a heat absorber is, of course, not subject to the above criticisms.

The reason for the short tests was the impossibility of operating for a longer period at the heavy overload. It will be noted that the coal used was very high in sulphur. The resultant difficulties with clinker building out from the bridge wall prevented continuing these tests over eight hours. The eight-hour test was adopted for this investigation only after considerable experimentation. It was found that very small changes in the fuel supply could be readily observed in their effect upon the fuel-bed thickness. In considering the accuracy of the tests it must be remembered that firing conditions were kept very constant. Every effort was made to this end. Under such conditions objections to the eight-hour test are minimized. In view of the observed fact that cutting off the fuel supply for five minutes produced an easily observed change in the fuel bed, the author feels justified in claiming

an accuracy of efficiency figures within a 3 per cent limit of variation.

Mr. Spitzglass speaks of the author's failure to study the relation between efficiency and capacity. The author would say here that, assuming the possession of complete data on the operating characteristics of a steam boiler, the study of the above relation must necessarily be a prolonged affair. It involves the loading conditions of the plant, prices of coal and labor, cost of equipment and of land and other conditions affecting power costs. Manifestly it could not be so much as touched upon in the present paper. All that the author hoped to do was to establish the importance of the relation of efficiency to capacity in the boiler as the prime basis of the investigation which has been presented.

Mr. Spitzglass also questions the ability of the fireman "to observe air velocities, draft-gage readings, gas analysis and the flue temperatures," or to interpret such readings. As regards flue-gas analyses, the author fully agrees with Mr. Spitzglass, and takes great pains in the paper to point out how the conditions of combustion may otherwise be easily and simply indicated. As regards the observing of air velocities, the author believes that the air meter, an illustration of which is shown in the paper, may be read as easily as any other form of meter. Concerning the use of instruments in general, the practice of the best plants throughout the country is a sufficient answer. The author heartily subscribes to the value of the steam-flow meter as mentioned by Mr. Spitzglass.

The author wishes to correct the impression that may have been gained that he ever had in mind the use by the fireman of charts such as have been presented in this paper. He would, however, propose the use of scales on the various instruments, having the numbers so arranged as to correspond when operating conditions are proper; e.g., all numbers indicating 5 when No. 5 load is to be carried. Such a system would be readily intelligible to the fireman.

Messrs. Alpern and Reinicker both call into question the matter of air-pressure drops through the tuyeres and fuel bed (i.e., sum of pressure in air boxes of stoker and draft in combustion chamber). Clearly this drop is a function of the amount of air forced through the fuel bed, the areas of air openings in the grates, and the thickness and resistance of the fuel bed. The criticisms seem to assume ability on the part of the operator to regulate this pressure drop independently of load. Such cannot be the case, since any increase in air pressure with a given condition of fuel bed will simply result in a greater combustion rate and will not change proportionately the ratio of air to coal burned. This ratio may be regulated only by regulation of the fuel-bed resistance.

Mr. Alpern speaks of "some operating faults of the tests." The author has nowhere indicated that the air supply to the extension grates was kept continuously at the maximum, nor does Mr. Alpern's discussion indicate to him any faults in operation. The point is that at heavy overloads it is obviously necessary to increase the combustion rates on all parts of the grate surface. This necessity applies to the extension grates as well. The author does not believe that the maximum supply of air to these grates is sufficient for prolonged overloads in the stoker under discussion. Mr. Alpern's statement regarding the relation of air pressures to the different fuel-bed thicknesses is not in accord with the data given in the paper. The author certainly agrees with Mr. Alpern that "the heavy-fuel-bed condition was an unnatural one."

In answer to Mr. Reinicker's statement that the furnace drafts were too high, the author would say that in the particular setting tested, lesser drafts could not be used without driving some gas out of the setting near the top of the first pass and without endangering dump-grate bars. The author fully agrees with Mr. Reinicker as regards the limitations placed upon both capacity and efficiency by high furnace temperatures. Difficulties from clinker and destruction of the refractory lining are perhaps the greatest single barrier operating against heavy overloading. Mr. Reinicker's statement regarding the unimportance of radiation and convection as *losses* and his criticism based thereon have no bearing on the paper under discussion. The author treated radiation and convection as the modes of heat transmission from the furnace to the boiler, and at no point considered their bearing upon the incidental losses from the setting.

In the first paragraph of his discussion, William Kent has put in a few words and in admirable form the idea that has been in the mind of the author for some years, and which led to the preparation of this paper.

Victor B. Phillips.

Ft. Leavenworth, Kan.

DISCUSSION OF PAPER ON METAL PLANERS AND METHODS OF PRODUCTION

To the Editor:

Regarding Mr. Barth's statement in his discussion that the time consumed in stopping and reversing the planer and table must be independent of the length of the stroke and can be considered equal to the time it would take the table to travel an imaginary addition to its actual stroke, I think this is where the misunderstanding comes in. I take it Mr. Barth believes a constant can be found which would be correct for all lengths of strokes. This is impossible owing to the variable quantities governing the different belt conditions; for instance, on long strokes, where the reversals are less frequent, the pulleys do not heat up and the belt slips less than it does on short strokes. It is a positive fact that if a planer is run for any length of time on short strokes (especially with cast-iron pulleys) the belt conditions are continually changing, owing to the slipping of the belts and the heating of the pulleys and the air which seems to get between the belt and the pulley. This condition becomes a great deal more aggravated on short strokes than it does on long strokes, and even at times I have seen it get to a point where the belts would smoke terribly. Anyone who has stood and watched such a performance and observed the variation in the length of stroke will admit that no practical constant can be found which will be correct for all conditions and for all the lengths of strokes.

As to the imaginary length of a perfect stroke, why try to determine on this imaginary quantity when the actual quantity can be so easily figured? Knowing the cutting and return speed and assuming there is no loss at either end, we have the actual ideal condition, which is the theoretical number of strokes I referred to in Table 1.

In making our aluminum pulleys, we aim to get as close to this theoretical or ideal stroke as possible, and just how near we have approached this condition is represented by the efficiency column, from which it can be seen that no one constant can be found to cover all lengths of strokes which would be correct; because what would be correct for the average long strokes would not be correct for the shorter strokes. A graphical diagram, such as is shown in Mr. Barth's Fig. 1, could not be determined, therefore, as the values of *a* would be variable for different-length strokes.

I cannot see that Mr. Barth's contentions are at all well founded, and I believe if he will carefully analyze the prac-

tical side of these points, he will agree with me that I am correct in what I have said.

Charles Meier.

Cincinnati, Ohio.

To the Editor:

I appreciate fully what Mr. Meier says in regard to the absurdity of my contentions about a constant imaginary over-run for very short strokes, but as I never allow any planer to run on such absurdly short strokes, it did not occur to me to qualify my statement, as I have now done in correcting my discussion. However, I can assure him that I have too often demonstrated that my contention is correct for all practical purposes, to admit that there is any misunderstanding about this matter, on my part. Besides, the accompanying plot, Fig. 1, of his experiments clearly shows that his shortest stroke did not adversely influence the effective pull of the belt, which, in fact, indicates a higher effective pull on the shortest stroke, both for the cast-iron pulleys and the aluminum, provided any reliance can be placed on his experimental figures in

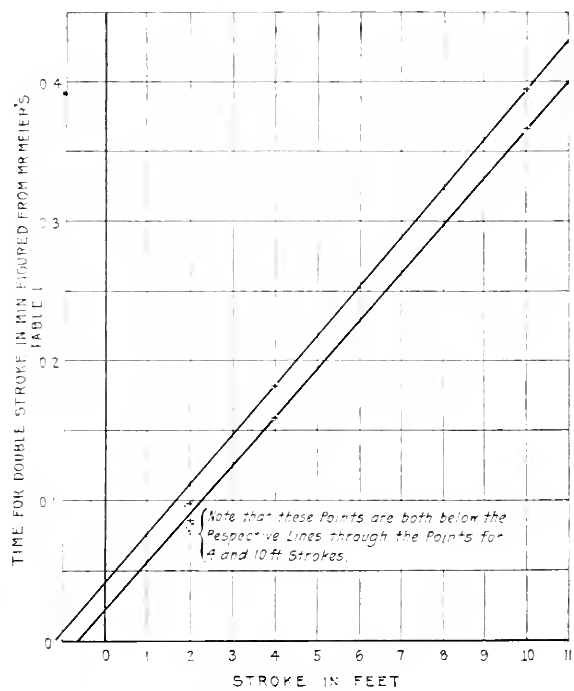

Fig. 1 Plot of Mr. Meier's Experiments

Table 1. I may say, in this connection, that I certainly cannot approve of Mr. Meier's way of figuring the theoretical number of strokes from the theoretical speeds 40 and 90 ft. It savors too much of time studies that give nothing closer than 0.1 min. You can arrive at such matters by indirect methods only.

Regarding the power question, in Par. 11 of his paper, Mr. Meier makes the unqualified statement that the aluminum pulleys show a saving of 25 per cent in power, which, taken by itself, is very misleading, though of course he did not mean it that way. I therefore suggest that he rewrite it something like the following:

"11. Table 2 also shows, what we should expect to find, some reduction in the peak load on the motor during reversal, namely 25 per cent, with the aluminum pulleys as against the cast-iron pulleys.

Carl G. Barth.

Philadelphia, Pa.

The Society of Industrial Engineers, which was recently organized at Washington, D. C., consists of professional technical engineers, accountants, managing executives in commercial and industrial activities, technical writers, educators and students. It is planned to offer the services of the organization to the Government through Howard E. Coffin, chairman of the Advisory Committee, Council of National Defense, and through such committees as can use the services of industrial engineers. A bureau has been organized under the direction of the president of the society to list all the industrial specialists in the country who may be called upon to serve either as advisers or directors of efficiency work. D. C. Dent, of Chicago, is acting secretary of the organization.

Standard wrought-iron or steel pipe of any size up to and including 10-in. is with three exceptions larger in diameter internally than its specific designation would indicate. Ordinary 1-in. wrought-iron pipe, for example, when made to conform exactly to standard dimensions (which, however, is not always the case) has an internal diameter of 1.05 in., which is 1-20 in. over the nominal size.

On the other hand, extra strong pipe having a higher designation than ½-in. and up to 12-in. is smaller in diameter, with one exception, than the nominal size would indicate. Thus, extra strong 1-in. wrought-iron pipe is 0.95 in. diameter inside, which is 1-20 in. under the nominal size, while double extra strong 1-in. pipe has an actual internal diameter of only 0.60 in., or a little more than half the nominal value.—*Power*, July 17, 1917.

The Shipping Board has announced a call for engineers to serve on the great war fleet that is to be built. It is announced that in the next 18 months no less than 5000 engineers will be needed.

Engineering schools in terms beginning July 21 will be opened at the Massachusetts Institute of Technology, Cambridge, Mass.; at Stevens Institute, Hoboken, N. J.; at the Case School of Applied Science, Cleveland, Ohio; at the Armour Institute of Technology, Chicago, Ill.; at the University of Washington, Seattle, Wash.; and at Tulane University, New Orleans, La.

Each term will last one month, the expense of tutoring being borne by the Shipping Board. The Massachusetts Institute of Technology, it is said, can put through 150 students a month, and other institutions an average of 35 students. Marine engineers of all grades, oilers, water tenders, and stationary engineers are eligible for the classes. (*Christian Science Monitor*, June 23, 1917, p. 3.)

The Chemical News and Journal of Physical Science (vol. 15, no. 3003, June 15, 1917) announces a unique British invention, namely, a secret process for manufacturing rubber sponges.

In making certain rubber goods a "fault" was developed. Its cause was traced and out of it the artificial sponge gradually emerged.

Within the last five years, however, a similar product has been manufactured in America. It appears now that an English inventor, G. W. Leeson, has produced an artificial sponge which is claimed to be superior to those now on the market, as with or without soap it has not the slightest trace of roughness and, in addition, the new sponge retains its freshness for a long time.

WORK OF THE BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in THE JOURNAL, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee as approved by the Council on June 21, 1917, in Cases Nos. 150, 153-157 and 159-161 inclusive. In this report, as previously, the names of inquirers have been omitted.

CASE No. 150 (REOPENED)

Inquiry: Is it permissible under the rules of the Boiler Code to brace that portion of the head of an h.r.t. boiler below the tubes with diagonal braces, or must this portion of a boiler be braced with through stays?

Reply: Diagonal bracing is not permissible for that portion of the front head of an h.r.t. boiler which comes below the tubes, under Par. 218 of the Code, but it is permissible for the corresponding portion of the rear head.

CASE No. 153

Inquiry: Does the crowfoot brace illustrated in Fig. 7 meet with the requirements of Par. 223 and Table 4 of the Boiler Code?

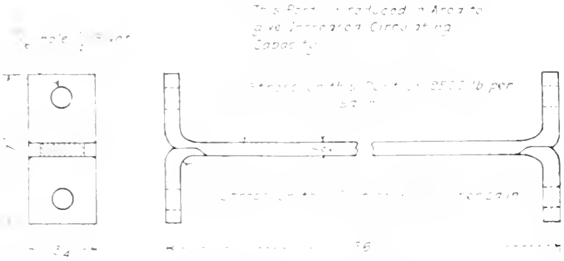

FIG. 7 PROPOSED SIDE BRACE FOR 150 LB. W. P.

Reply: The strength of each branch of the crowfoot in the design shown is difficult to compute. As the crowfeet vary so widely on different braces, it was the idea of the Boiler Code Committee in formulating this rule that the manufacturer would test each type of brace made to determine whether it meets the requirements or not, and the Committee suggests that the braces be tested to determine the relative strength of the body of the brace and of a crowfoot. According to the rule, the foot of the brace should be one-third stronger than the body of the brace. It, therefore, follows that if a test brace is made with the body one-third stronger than the brace to be used, the crowfoot of this test brace should be as strong as the body of the brace.

CASE No. 154

Inquiry: In the staying of a segment of a head, above the tubes, of an h.r.t. boiler in which a manhole is inserted, is there an allowance of 100 sq. in. under the rules of the Boiler Code, as is allowed by Par. 218 for manholes inserted in heads below the tubes?

Reply: Where a manhole is placed above the tubes in an h.r.t. boiler, no allowance shall be made as for the head surface that need not be braced, and the bracing of the head with such manhole opening should conform to that which would be used provided there was no manhole.

CASE No. 155

Inquiry: What is the application of the rules in Part I, Section 2, of the Boiler Code to the workmanship on steel plate heating boilers? Are punched rivet holes permissible, and also may cast iron mud rings and door frame rings be used?

Reply: The Code does not require the drilling of rivet holes for boilers for low pressure heating or hot water supply, except those that come under the power boiler rules as specified in Par. 335. This also applies for cast iron mud rings and door frame rings, where used.

CASE No. 156

Inquiry: *a* Will brass or bronze valves and fittings with flange ends in accord with the "1914 Brass Standard Flange Dimensions," when bolted to ferrous fittings as prescribed in Code Tables 15 and 16, comply with the purpose and intent of the Boiler Code Committee's reply in Case No. 101?

b Does the Boiler Code Committee approve the recommendation that the raised face be removed from a Table 16 fitting when it is bolted to a brass or bronze fitting?

c Does the Boiler Code Committee approve the recommendation that full face gaskets be used in a non-ferrous to non-ferrous or a non-ferrous to ferrous flange joint?

Reply: *a* The standardization of bronze fittings has been referred to a special committee of the Society. Until a report upon such standards is prepared and accepted by the Society, the Boiler Code Committee will abide by the decision in Case No. 101.

b All dimensions shall conform to the American Standard given in Tables 15 and 16 of the Appendix for the pressures therein specified, except that the face of the fitting to which it is attached shall be flat and without the raised face where brass or bronze composition fittings are used.

c It is the opinion of the Committee that full face gaskets should be used.

CASE No. 157

Inquiry: *a* Will cast iron, dove-tail lugs be permissible under Pars. 323 and 324 of the Boiler Code?

b In empire and economic type boilers, where the pads on the cross braces form a reinforcement to the side sheets, what coefficient should be used under Par. 199 of the Boiler Code?

c A ruling is desired covering Par. 254 of the Boiler Code, if no burrs are present.

Reply: *a* This inquiry is answered by Case No. 151.

b According to Par. 203, the value of C to be used should be 135.

c It is the opinion of the Boiler Code Committee that the plates should be separated to make sure there are no burrs.

CASE No. 158

(In the hands of the Committee)

CASE No. 159

Inquiry: If the material of which a dished head is formed is thicker than necessary under the rules of the Boiler Code

to sustain the pressure carried, is it necessary to flange a manhole opening, if inserted, to a depth of three times the thickness of the material used?

Reply: The intent of Par. 198 of the Code is that a manhole opening in a dished head shall be flanged to a depth of not less than three times the required thickness of the head, measured from the outside. If, therefore, the required thickness of material for a head is ½ in., the opening needs to be flanged to a depth of not less than 1½ in.

Case No. 160

Inquiry: Does Par. 316 of the Boiler Code allow the feed inlet to be located 3 in. from the bottom tube sheet of a small, vertical laundry boiler?

Reply: The Committee has decided that the requirement of Par. 316 does not apply to a small laundry boiler of the type you describe.

Case No. 161

Inquiry: Does Par. 218 of the Boiler Code prohibit the hexagonal or beehive arrangement of tubes used in the design of h.r.t. boiler shown in Fig. 8? The reply in Case No. 142

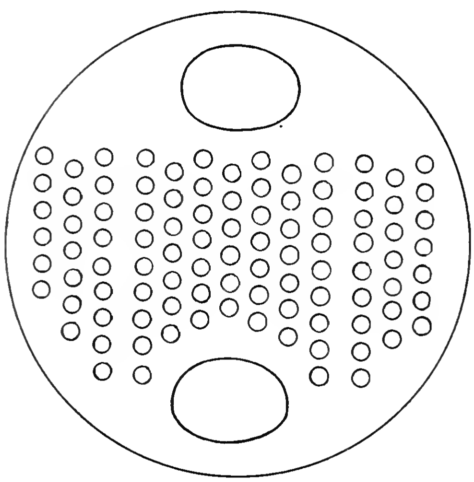

Fig. 8. Hexagonal Arrangement of Tubes in H.R.T. Boiler

is taken to apply to the usual tube layout, and does not seem to apply to the special tube layout, there shown.

Reply: The reply in Case No. 142 applies irrespective of the tube arrangement in an h.r.t. boiler.

Revision of Boiler Code

The Council of the Society has directed that the proposed changes in the Boiler Code be published in The Journal, with the request that any desired discussion on the proposed changes be mailed to the Boiler Code Committee for consideration. These proposed changes embody suggestions made at the meetings held at the Society headquarters, December 8 and 9, 1916, which were widely advertised as public meetings to which all those interested were invited to attend and participate in the discussions. Publishing the proposed changes will make it possible for any one to discuss the revisions before they are brought to the final form and presented to the Council of the Society for approval. All suggestions will be gratefully received and will be carefully considered by the entire Committee, and a full and free discussion is solicited.

A number of proposed revisions were published in the June issue of The Journal. There are other revisions which will be published later on with the request that they also be discussed.

PAGE 12

Par. 29a. Change Par. 29a to read as follows:

29 *Modifications in Elongation.* a For material over 11/16 in. in thickness, a deduction shall be made from the percentage of elongation in Par. 28a of four times the thickness in inches in excess of 11/16 in. to a minimum of 20 per cent.

Par. 30a. Change Par. 30a to read as follows:

30a Tension test specimens shall be taken longitudinally from the bottom of the finished rolled material, and bend test specimens shall be taken transversely from the middle of the top of the finished rolled material. The longitudinal test specimen shall be taken in the direction of the longitudinal axis of the ingot, and the transverse test specimen at right angles to that axis.[1]

Par. 30b. Change Par. 30b to read as follows:

30b The test specimen shall bend cold through 180 deg. without cracking on the outside of the bent portion, as follows: For material 1 in. or under in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for material over 1 in. in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen.

PAGE 13

Par. 33a. Change Par. 33a to read as follows:

33a *Number of Tests.* One tension and one bend test shall be made from each plate as rolled.

Par. 335. Change heading which now reads "Boiler Materials" to "General."

A New Size of Boiler Stamp

When the A.S.M.E. Boiler Code was first issued early in 1915, stencil stamps conforming with the requirements of Par. 332 were prepared by the Society and offered to the public. The stamps were made ¾ in. in diameter and conformed generally with the exterior proportions of the Society emblem. They were widely distributed among boiler manufacturers and are now in extensive use in all parts of the country, seventy stamps in all having been issued up to the present time under the Boiler Code Committee's supervision.

In using a stamp of this size on plates ¼ in. thick or less, the rebound made it difficult to obtain a legible impression unless great skill was used in the stamping process. As a result of this difficulty, an inquiry concerning the matter was placed before the Committee. It was considered as Case No. 139 at the March 16 meeting, and treated as follows:

Case No. 139

Inquiry: Is it possible to secure a smaller A.S.M.E. boiler stamp than the present ¾-in. stamp that is furnished to meet the requirements of Par. 332 of the Boiler Code? It is difficult to stamp thin plates with the present ¾-in. stamp on account of the rebound.

Reply: A new stamp will be provided, ½-in. size, hammer

[1] Exceptions made for tension test specimens for plate which is rolled longitudinally with reference to position when used in a boiler shell. See Par. 190.

types [illegible] can be either used [illegible].

The Boiler Code Committee [illegible] nounce that a new [illegible] stamp [illegible] in the form of a hammer stamp, with the [illegible] emblem reduced to [illegible] in., as illustrated in Fig. 1. The reduced size of the emblem will greatly facilitate the stamping [illegible] thin plates, and where desired the impression may be obtained by using the stamp as a hammer instead of as a sledge in the usual manner.

Fig. 3 HAMMER STAMP FOR A.S.M.E. STANDARD BOILERS

Manufacturers desiring stamps are reminded that applications either for new or old size stamps must be accompanied by an affidavit made out on the form provided by the Committee and properly executed according to the following resolution approved by the Council:

> It is the opinion of the Committee that the official symbol or stamp is to be used to indicate that The American Society of Mechanical Engineers' rules have been compiled with in the construction of the boiler. The stamp shall be affixed by the manufacturer. Certification to be governed by law or contract.

The blank affidavit form may be obtained upon application to the Boiler Code Committee at the Society headquarters.

In an effort to coöperate in the solution of various problems of vital importance to the development of the French industries, the French Society of Civil Engineers decided to organize a Congress of Civil Engineering, which, in its idea, would constitute something like General Assizes of the Industry for the study of a program to be carried out after the war.

According to a preliminary announcement, the work of this congress will be divided into two groups and several sections.

The first group, embracing Sections 1 to 7, will be of a technical character and will be devoted to the following specialties: Section 1, public works and civil constructions; Section 2, transportation; Section 3, mechanical engineering, motors and machine tools; Section 4, mining and metallurgy; Section 5, industrial physics and chemistry; Section 6, industrial applications of electricity; Section 7, farm engineering and agricultural industries.

The second group, comprising three sections, will be devoted to economic problems and divided as follows: Section 8, rational organization of industrial works; Section 9, social hygiene, accident prevention, healthful work; Section 10, industrial legislation.

It is expected that the first part of the congress, i. e., the National Congress, will be held next November and will be opened to all interested in the economic and industrial future of France. The terms of admission have not yet been announced.

As regards the Inter-Allied Congress, for many reasons it is not expected that it can be organized until after the termination of the war. (Announcement in *Le Génie Civil*, vol. 70, no. 23, June 9, 1917, p. 373)

Tests of aeroplane engines will be made at a laboratory at the Bureau of Standards. At a recent meeting of a subcommittee on power plants of the National Advisory Committee for Aeronautics preparations were made for the development at the Bureau of Standards of a laboratory for testing aircraft engines under conditions of altitude and temperature similar to those encountered in flights at an altitude of 20,000 ft. or more. The laboratory and its experimental equipment will be organized under the auspices of the Advisory Committee, and the investigations will be directed by the subcommittee on power plants. (*The Automobile and Automotive Industries*, vol. 37, no. 2, July 12, 1917, p. 82)

The Autogenous Welding Committee of the American Society of Refrigerating Engineers has been appointed and consists of the following members: F. L. Fairbanks, Mem.Am.Soc. M.E., chairman; Llewellyn Williams, Mem.Am.Soc.M.E.; S. F. Jeter, Mem.Am.Soc.M.E.; P. A. E. Armstrong, metallurgical engineer, the North American Co.; Charles H. Bromley, associate editor *Power;* James C. McCabe, Mem.Am.Soc.M.E.; Theo. Vilter, president Vilter Manufacturing Co., Milwaukee, Wis.; Prof. Edward F. Miller, Mem.Am.Soc.M.E.; John E. Starr, Mem.Am.Soc.M.E., and Thomas Anderson, refrigerating inspector, City of Chicago.

The purpose of the committee is to assist in the development of the welding art and to make its application to pressure vessels as safe as the best knowledge of the subject can make it.

The government of the Union of South Africa has appointed an advisory board to deal with the development of the natural resources of the country. A special scientific and technical committee has been appointed to carry out scientific investigations. This committee consists of Mr. J. Burtt-Davy (botany and agriculture); Mr. L. Colquhoun (chemistry); Professor Young (geology); Professor John Orr, Mem. Am.Soc.M.E. (mechanical engineering); Mr. Bernard Price (electrical engineering); Professor Beattie (physics); Dr. Caldecott (metallurgy); Professor van der Riet (chemistry); Professor Malherbe (chemistry); Dr. L. Peringuey (president of the Royal Society of South Africa). The first step taken by the new committee has been to arrange for the preparation of fifty-two reports by leading experts, dealing with the available raw materials of South Africa suitable for manufacture or export. It is intended that these reports shall be published for the guidance of intending manufacturers and other business men.

In reply to a query from E. P. V. Ritter, of the Merchants and Manufacturers' Exchange, New York City, asking about the advisability of holding conventions during the war, the President has sent the following letter:

"In reply to your letter of June 4, allow me to say that I not only see no reason why commercial conventions should be omitted during the war, but should regret to see any instrumentality neglected which has proved serviceable in stimulating business and facilitating its processes. This is not only not a time to allow any slowing up of business, but is a time when every sensible process of stimulation should be used.

Cordially and sincerely yours,

(Signed) Woodrow Wilson."

(*Journal of Commerce*, June 18, 1917, p. 1.)

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

APART from the regular monthly departments, this issue of THE JOURNAL is practically devoted to the Sections of the Society, the Proceedings Section containing papers presented and discussed at Section Meetings, the publication of which will be continued in the next issue, and the Society Affairs Section containing reports of the year's activities received from the respective chairmen of Sections.

In reading these accounts of Sections work, members of the Society will become impressed with the increasing importance and tremendous possibilities of this activity of the Society, whereby we are able to bring the Society work in direct touch with eighty per cent of the whole membership.

Quoting from Vol. 31 of the Transactions, only eight years ago, during the presidency of Mr. Jesse M. Smith, "A meeting of members of the Society residing in St. Louis and vicinity was called by Wm. H. Bryan, member of the Meetings Committee. Prof. E. H. Ohle acted as secretary and about twenty engineers were present. This was the first local meeting of the Society to be held outside of New York City." Boston almost simultaneously held its first meeting. All the development of the Sections has come within the space of eight short years, and has now reached a magnitude that 112 local meetings were held during the season just closed.

The President, Dr. Hollis, proposes to further accentuate the national character of the Society by instituting the holding of Council meetings in various cities. The Council meeting for November will be held in Chicago. This will bring together a larger number of the officers of the Society than would ordinarily be brought in connection with one of the local meetings, it being planned to adjust the date of the Council meeting to the same day as that of the Chicago local meeting.

The President contemplates in the early fall a visit to the Coast. With this trip he will have attended meetings of the Society in all of the centers where we have established Sections.

The Committee on Sections also contemplate holding meetings next season in various cities where Sections meetings will be held. In this way an intimate knowledge will be gained of the requirements in different parts of the country. The first meetings will probably be held at St. Louis, Chicago and Detroit, during the month of October. By arranging meetings at these cities on consecutive days the committee will be able to visit several cities in one week with a saving in traveling expenses and the time of the members of the committee. These meetings will be arranged to fall on dates when the monthly meeting of the Section is being held, so that the members of the committee will not only have opportunity to meet the Executive Committee but also all members of the Section. In this way it is hoped that all Sections will be visited at least once every two years.

This will tend to bring all members into close association with the work the Society aims to accomplish through Section activities, and will also give the members opportunity to get first-hand information regarding matters of vital interest to them.

CALVIN W. RICE,
Secretary.

WHAT THE SECTIONS HAVE DONE THIS YEAR

A CLOSE association between the various local organizations of other societies representing the divisions of engineering practice and our own Sections has resulted in the holding of a large number of joint meetings during the season just closed. The largest of these meetings was that held in November 1916, when the Sections from Boston, New Haven, New York and Worcester and the Providence Engineering Society, affiliated with our Society, met with a number of engineering organizations in a visit to New London, Conn. There were over 1600 present on this occasion, and the event was described in detail in the December issue of THE JOURNAL.

The title of the Associated Technical Societies of Baltimore indicates that a plan of full coöperation of the engineering organizations has now been achieved in that city. In Buffalo our Section has coöperated with the Buffalo Engineering Society to the mutual benefit of both, while the Cincinnati Section is affiliated with the Engineers' Club of Cincinnati and takes charge of three or four of the joint meetings held each year. In Erie the Section has developed relations with the Engineers' Society of Northwestern Pennsylvania, and plans are being perfected whereby it will supply the speakers at two of the joint meetings of the season. Very cordial relations exist between the Minnesota Section and the other engineering societies of that state, and there have been joint meetings with the local branch of the American Institute of Electrical Engineers. The plan of affiliation of the Philadelphia Section with the Engineers' Club is working very successfully and Philadelphia is being pointed to as an example of coöperation of engineers. Joint meetings have been held during the year with The Franklin Institute and with the American Society of Heating and Ventilating Engineers. The meetings in Providence have been those of the Providence Engineering Society, affiliated with our Society. The Section meetings in New Orleans have been held jointly with the local branch of the American Society of Civil Engineers and the Louisiana Engineering Society. New Haven is organizing a Connecticut State Section to secure more complete coöperation, and a meeting of the Bridgeport branch of this Section has been held during the past month; the work in this state has developed a new field for Sections activities. In Atlanta the Section is coöperating with the Affiliated Technical Societies there. The Detroit Engineering Society and the local Section of our Society are working in complete harmony for the development of the profession in that busy center, and joint meetings are held by both organizations with the Detroit Branch of the Society of Automotive Engineers.

The reports from the various Sections of the year's work indicate more fully how this spirit of cooperation, of which the above are potent examples, is being developed. These reports show also how the Sections are joining with local branches of the other national societies in their meetings, and are thus carrying out in an equally effective way the work which the parent societies are endeavoring to do nationally.

THE SECTIONS AND THE SOCIETY

At the Annual Meeting in December the third Conference of Sections was held, when the official delegates of sixteen Sections and the representatives of five centers contemplating the establishment of Sections met with the Committee on Sections. One session was devoted to an "experience" meeting, at which each delegate reported the work of his Section during the past year and plans for the ensuing season. The conference led to a better understanding of the problems with which each Section has to deal and developed ways and means for their ultimate solution.

The Committee on Sections also held a luncheon and business meeting at the Spring Meeting in Cincinnati in May 1917, at which seventeen Sections were represented. That the coöperation of the Sections might be even more complete, it was urged at this meeting that there be an exchange of literature and notices of meetings between the Sections.

At the Spring Meeting, also, the Committee on Constitution and By-Laws presented an amendment to the constitution recommending that the Committee on Sections be made a Standing Committee of Administration of the Society and that it have a seat on the Council without vote.

A NEW DEVELOPMENT IN SECTION ORGANIZATION

The Connecticut members are developing a new method of section organization in the nature of a State Section, with branches at the important industrial centers of the state. Heretofore the requirements of the members of that locality were met by the activities of the New Haven Section. This Section has been holding two meetings annually for some time—one in the fall and the other in the spring. These meetings were held at Yale University, and through them the Society has grown in Connecticut to such an extent that a more comprehensive program has been found desirable. This movement has, in a measure, been prompted by a feeling on the part of the members in other localities of the state that it was unjust to continuously put upon the New Haven members and Yale University the burden of arranging the meetings, because all of the members of the Society in the state of Connecticut were always invited to the meetings of the New Haven Section.

The members of the New Haven Section have set an excellent example in coöperation by not only unselfishly stepping aside to make way for the State Section, but by taking a leading part in its development.

About three months ago a meeting was held in Bridgeport at which were present members of the Committee on Sections, Secretary Rice, a majority of the members of the New Haven Section, and a large number of members of the Society representing various parts of the state. At that meeting the following organization committee was appointed: H. B. Sargent, chairman, representing New Haven; C. K. Decherd, representing Meriden; Harry E. Harris, representing Bridgeport; S. F. Jeter, representing Hartford, and E. S. Sanderson, representing Waterbury.

A formal petition has now been submitted for the establishment of a Connecticut Section, with branches at New Haven, Bridgeport, Hartford, Meriden and Waterbury. Each branch will be governed by an Executive Committee of five members, the chairmen of the five branches composing the Executive Committee of the State Section.

The Bridgeport branch organization committee met on the evening of July 16 at the Algonquin Club, and tentatively selected the following officers: H. E. Harris, chairman; F. R. Pleasonton, vice-chairman; R. W. Ellingham, treasurer; E. L. Fletcher, secretary; C. W. Burges, chairman of Committee on Increase of Membership. The other proposed branches will soon organize, so that the whole scheme may be put into effective working order by the beginning of the new fiscal year, on October first.

NEW SECTIONS

New Sections have been established during the year at Baltimore, Erie, Indianapolis, New Orleans and Ontario, the headquarters of the last being at Toronto. This brings the total number of Sections up to twenty-one.

LOCAL ORGANIZATIONS

In several cities in which the number of members of the Society is not sufficient to organize a Section, the members meet together or with existing local organizations periodically. The accounts of these meetings have been published during the year with the regular Section reports.

The Committee on Sections is anxious to extend the benefits of the Society as rapidly and as far as possible. Obviously the initiative must be taken by the members themselves, and in those centers where the numbers and interest are sufficient to warrant meetings being undertaken.

The Society through the Committee on Sections is anxious to assist in the development of Sections work and makes appropriations to cover fixed expenses.

MEETINGS AND PAPERS

In the October 1916 issue an outline was given of the proposed Sections activities for the season. A report from each Section gave the number of meetings expected to be held, trips to be taken and entertainment features planned. As far as possible the papers which were to be presented were listed, thus giving a fairly complete program of the work laid out for the year.

To a large extent the programs in each city have been carried out as planned. In all 112 meetings have been held this season, and all have been reported in THE JOURNAL. Eleven of the papers presented locally have been published in THE JOURNAL.

THE SECTIONS AND VISITS OF OFFICERS

In the fall of 1916 President Jacobus and Secretary Rice made a tour of the Sections and of the centers where members were contemplating the formation of Sections. President Jacobus delivered an address in Buffalo on the relations existing between the parent Society and its Sections and on coöperation between the Sections and local engineering societies and clubs. The places visited were Meriden, Pittsburgh, Cleveland, Buffalo, St. Louis and Baltimore.

In January of this year President Hollis visited the Sections at Detroit, Chicago, Milwaukee, New Orleans, Birmingham and Atlanta. President Hollis's message to the Sections was service of the individual to society. In March Dr. Hollis made a

second tour which took him as far west as the Minnesota Section, whose headquarters are at Minneapolis-St. Paul. En route he visited the Sections at Buffalo, Chicago and Indianapolis, receiving a rousing welcome from all. His spirited address on Service to the Country in This Crisis brought forth enthusiastic responses. He has also spoken before the members of the Sections at Boston, New York, Philadelphia and Worcester, and the Providence Engineering Society.

In April Secretary Rice supplemented President Hollis's visits by a tour to the Sections at Cincinnati, Chicago and Milwaukee, and to Madison and Oklahoma City.

The President expects to make a trip to the Coast in the fall and visit the Sections there.

SECTIONS REPORTS FOR THE YEAR

At the close of the season's work the Sections have sent in reports to headquarters giving detailed accounts of their work. Some of these reports are published below and the remainder will be included in the next issue of The Journal.

The thanks of the Society are due to the Executive Committees of the Sections whose terms of office have just expired, for the personal time they have devoted and labor spent in continuing and fostering this very important activity of the Society. To maintain the full measure of coöperation and of amicable relations with other engineering societies which the Sections enjoy calls for the exercise of a great deal of tact and perseverance on the part of committee members, and the Society has cause for congratulation because of the fine spirit in which this work has been conceived and carried out during the past season.

Sections Reports

BALTIMORE

The Baltimore Section was organized at a meeting on October 19, 1916. President Jacobus and Secretary Rice attended the organization meeting.

In organizing the Section it was realized that its work could be made much more effective if the mechanical engineers could secure the coöperation of all the other engineers in the city. It was felt that a joint organization of engineers in Baltimore would tend towards greater interest in each particular section and also in matters of general engineering interest. Steps were therefore taken at the outset to bring about such a coöperative organization. Following a number of conferences the Associated Technical Societies of Baltimore was formed of all local technical societies and the local sections of the national engineering societies. Each local organization invites members of all sections of sister societies to all its meetings, except those of a strictly business character. It is hoped that later on this association may develop a close union and that the joint organization will be one of considerable influence.

The first year of the Section's activities has been marked with many meetings of interest with such subjects and speakers as Work of the Navy Experiment Station, by W. F. DeBaufre, Mem.Am.Soc.M.E.; Recovery and Use of By-Products from Coal Tar, by F. H. Wagner, Mem.Am.Soc.M.E.; Flow of Values Through an Industrial Plant, by Harrington Emerson, Mem.Am.Soc.M.E.; Safety First on the B & O, by J. T. Broderick, and Munitions and Preparedness, by Alten T. Miller.

The formation of a Section in this city has stimulated interest in the Society, as evidenced by the increased membership during the past year; it has also encouraged the formation of a Student Branch at Johns Hopkins University.

The outlook for next fall is most encouraging and it is anticipated that the four meetings already planned for next winter will prove of even greater interest to engineers than those of the past year.

C. C. Thomas,
Section Chairman.

BUFFALO

The Engineering Society of Buffalo was organized in 1912 from a group of members of the A. S. M. E., and by a sturdy growth it has absorbed the entire activities of the local Section. The *why* of the E. S. B. is "coöperation," the greatest force in the world today.

Today the society has a membership of over 500, comprising the various branches of professional engineering, mechanical, electrical, chemical and civil, all of which are splendidly represented. The society believes that the intermingling of engineers of somewhat different interests is broadening to all, and conducive to the greater effectiveness of the influence of engineers on questions affecting the general public welfare, as well as to the advancement of the profession nationally.

Every two weeks during the months of October to May, inclusive, meetings are called in the Hotel Statler, and the average attendance is about 200. Preceding each meeting a dinner is served to promote social intercourse of members and their guests.

Bulletins are prepared announcing all meetings, and for special meetings display posters are used. Return postal card notices of meetings are also forwarded to all members.

A practice is made of inviting the more prominent business men and heads of manufacturing establishments to the meetings.

Each year there has been an increase in interest and attendance at these meetings, but the season just closing has been marked by more ambitious programs and an even more enthusiastic attendance. In arranging the program for the year special attention was given to securing subjects of general rather than specific technical interest in order to stimulate enthusiastic support from the entire local membership. An analysis of the program shows that effort has been concentrated upon making the subjects as broad as possible, and also of special interest in Buffalo and its vicinity. A similar series is being planned for next season.

John Younger,
Section Chairman.

NEW YORK

Following out the plan inaugurated toward the close of the preceding year, the activities of this Section were carried out along three distinct lines: namely, the regular monthly meetings, at which papers or addresses were delivered; social evenings under the direction of the Entertainment Committee, and excursions arranged and conducted by the Excursion Committee. In each of these activities the Acquaintanceship Committee assisted, and informal suppers before the monthly meetings were also effective in getting the members better acquainted.

The regular meetings were divided between technical papers and those of a semi-popular nature, the latter this year being chiefly on military topics. The technical papers were The Development of the Poppet Valve Steam Engine, by Siegfried Rosenzweig; Standards of Business Success, by Earle Buckingham; Narrow Gage Motor Cars, by C. W. Hunt, and an address by Dr. Ira N. Hollis. Among the semi-technical were those on Explosives, by Charles L. Reese, of the E. I. Du Pont de Nemours Powder Co.; Submarines, by Mr. Charles H. Bedell of the Electric Boat Co.; Mobile Armaments, by Andrew M. Coyle, and an address by Commander E. P. Jessop, U. S. Navy.

The average attendance was about 300, with a notable increase of the younger members of the Section.

During the first half of the year the Excursion Committee, under the direction of its Chairman, carried out a number of interesting and instructive Saturday-afternoon excursions, the largest of which was the trip to the submarine base at New London, in conjunction with the Boston, Providence, New Haven and Worcester Sections; 700 members and guests of the New York Section journeyed by special train on this excursion. The committee also conducted the excursions at the Annual Meeting. Unfortunately the war condition has prevented carrying out the plans of this committee during the latter half of the year.

Among other activities of the Entertainment Committee may be mentioned an informal smoker held early in the season, and a dinner-dance at the Machinery Club in April, both of which were largely attended.

H. R. Cobleigh,
Section Chairman.

PRESENTATION OF THE JOHN FRITZ MEDAL

THE John Fritz Medal, awarded to Dr. Henry Marion Howe in January of this year for his "investigations in metallurgy, especially in the metallography of iron and steel," was presented to him in the Auditorium of the Engineering Societies Building, New York, on the evening of Thursday, May 10.

Mr. Ambrose Swasey, Chairman of the John Fritz Medal Board of Award this year, presided at the ceremonies, and addresses were delivered by Dr. Rossiter W. Raymond, Secretary Emeritus of the American Institute of Mining Engineers, and Dr. Ira N. Hollis, President of The American Society of Mechanical Engineers.

Prof. Albert Sauveur, Chairman of the Board at the time the award was made, presented the medal, and the ceremonies concluded with the response of Dr. Howe. A full account of the proceedings at the meeting is given below.

HENRY M. HOWE

MR. SWASEY WELCOMES THE FRIENDS AND MEMBERS OF THE ENGINEERING SOCIETIES

In welcoming the friends and members of the engineering societies, and in introducing the first speaker of the evening, Mr. Swasey said: "It is a happy privilege that we can meet here this evening to honor one of our number who has distinguished himself in the profession of engineering, and that we may call to mind that splendid, noble character for whom the medal to be presented this night was named, and for whom it was established, and also call to mind the number who have received the medal as the years have gone on.

"I am sure we can but feel that this has been an elevating influence, a broadening influence, and that today, because of the John Fritz Medal, the engineering profession in this country occupies a higher plane and has a broader horizon than ever before. It has brought the different sections of the engineering societies together in a more coöperative way than has been in the years before, and I am sure that we all rejoice that these medals are awarded as we go along through life. I would that dear Mr. Fritz could take a part in and know of the work that is being undertaken in his behalf and in his name, in which he was so much interested.

"I remember one day we went down to the studio of the sculptor and he was extremely interested in the model for the medal which is to be presented this evening. He took much interest in every detail, not only as to the obverse, but as to the reverse side of the medal. In many ways he was identified with this work, and it is a great pleasure to think of him, of his sweet ways, and of the interest, not only as a great engineer, but of the great broad man he was in every respect, and I may say that we appreciate the noble works of those who have received the medal since his day, and we are glad to have one of the medalists with us here this evening in addition to the one who is to be the recipient of the medal that is bestowed this evening.

"I am sure you will be interested to have me read the names of those who have received the medals from time to time:

"The first was John Fritz, then came Lord Kelvin, George Westinghouse, Alexander Graham Bell, Thomas Alva Edison, Charles Talbot Porter, Alfred Noble, Sir William Henry White, Robert Wilson Hunt, John Edson Sweet, James Douglas, Elihu Thomson, and this evening Henry Marion Howe.

"This certainly is a splendid list of members and a great honor roll. Many have passed on, have ended their work here, and others are still going on with the work, but the names and the memories of those who have passed away still abide with us, and now this evening as we take up the ceremonies of presentation of the medal, I am going to first call upon one who needs no introduction, because you all know him because of the splendid work that he has done, for what he has accomplished for the engineering profession. We all have a deep affection for him, and therefore I am going to simply present to you Dr. Raymond."

DR. RAYMOND PRESENTS A FITTING TESTIMONIAL TO THE ACHIEVEMENTS OF PROFESSOR HOWE

Dr. Raymond, with his intimate knowledge of the life and the work of Professor Howe, delivered a very interesting and forceful address which is reproduced in full below:

"The genesis of a new science or branch of science is in this wise: First there is the invention of some new means or method of investigation, such as the chemical laboratory, the telescope, the microscope, or the spectroscope, followed at once by an innumerable host of startling, confusing, mostly qualitative observations. Such an invention reveals to mankind a dazzling but vague new world, the very existence of which was scarcely suspected before, and the indefinite outlines of which inspire poetic generalizations, and vast hypotheses—beautiful if true—beautiful, indeed, irrespective of their truth.

"Then comes the long period, less thrilling yet not less meritorious and even more important, during which the means and methods of observation are rendered more precise, and the recognition of differences more minute. At the same time, the older data are revised, corrected, and assorted—many,

probably most, of them, being rejected. This is the stage of preparation of the raw material of the science; and it is characterized in every science by the accumulation of a well-nigh intolerable burden of distinctly separated facts. But this burden must be patiently borne, and the separate units of which it is composed must be delimited, measured and weighed, in order that the mathematical, that is, the quantitative, character may be impressed upon them. Illustrations of this principle will occur to all who have followed the growth of any science.

"General Myer, the creator of our U. S. Weather Bureau, once told me that when he began to organize that service at Washington, he found in the garret of the Smithsonian Institution tons of old papers containing 'weather observations' contributed by public-spirited citizens all over the country who had heroically got out of bed at certain hours to read their thermometers, rain gages and weathercocks and anemometers. But nobody had tested or standardized their apparatus, and nobody guaranteed its freedom from accidental aberration or mischievous meddling.

"I have heard also of a great German mineralogist, who made many thousand measurements of crystals, and based upon their varying angles some beautiful hypotheses. But after his death, another mineralogist tested his goniometer, and found in it defects which vitiated his observations.

"Such are the pseudo-materials of science, which must be got out of the way before safe induction can begin. But even really scientific data may present, during the stage of verification and inchoate arrangement, an overwhelming complexity, which threatens to smother a new science in its cradle. Take, for instance, the condition of biology before Wallace and Darwin. Everybody was furiously busy detecting differences, and founding upon them the definitions of new species; and the mere catalogues of species were beyond the student's comprehensive grasp. We all remember the universal sigh of relief with which the scientific world, welcoming the Darwinian hypothesis as its new guide, began to study similarities and relationships instead of differences, and saw the incalculable multitude of individual species group themselves in a grand order, illuminated by a new law.

This emergence of a general formula from a chaos of equations marks the final stage in the genesis of a science. That is not the end, but only the beginning, of its history. It must still grow by accretion, subdivide by fissile separation, and establish its relations to other sciences. And at every step the operations of observation, verification, criticism, analysis and synthesis must be repeated, just as the embryo rehearses in miniature the history of a species.

"It follows that the stages of development which I have indicated, though they may seem, on the large scale, to follow one another, really go on *pari passu*. There is no time at which any one of them ceases. Yet with regard to a single and limited branch of scientific inquiry, their existence and succession may be clearly discerned.

"It is my difficult but honorable and welcome task to set before you an outline of the work of a master who has contributed mightily to all these phases in the growth of the new science of metallography; as a discoverer and observer, as an industrious compiler, and as the builder of a noble edifice out of the materials thus gathered and prepared.

"It is not my purpose to give a complete biographical and bibliographical statement. But I must say here at least so much as will indicate the peculiarly fitting endowment and environment by which this life and its work were determined and perfected.

"Henry Marion Howe was born March 2, 1848, at Boston, Mass. His father was Dr. Samuel G. Howe, famous for his service to Greece in her war for independence (from 1824 to 1830) and later for his labors in the instruction of the blind. His mother was Julia Ward Howe, author of the Battle Hymn of the Republic, and leader in many reforms. He was of good stock on both sides, making him heir to intellectual keenness and refinement, the capacity for both enthusiasm and perseverance, a passion for the pursuit of knowledge, and a gift of clear and felicitous statement.

"This inheritance was improved by a liberal education. No matter how vehemently the business or scientific value of a 'college course' may be controverted, I notice that, without exception, the successful men who have had such a course are glad they had it, and those who have not wish they had. We may be sure that Professor Howe's easy command of his field in technical literature owes much to the circumstance that he was graduated in 1865 from the famous Boston Latin School, and, four years later, received his degree as Bachelor of Arts from Harvard College. Thus equipped, he entered the Massachusetts Institute of Technology, which gave him in 1871 the degree of Graduate in the Department of Geology and Mining Engineering—a cumbrous title for which the institution substituted, a few years later, that of Bachelor of Science. And Harvard made him Master of Arts in 1872, and Doctor of Laws in 1905.

"But upon this basis of wide and liberal culture it was necessary to his future achievements that he should lay another foundation of acquaintance with practice; and this he did during the next dozen years, as a student in the steel works at Troy, manager of works at Pittsburgh, and designer and builder of the works of the Orford Nickel and Copper Co. at Capleton and Eustis in the province of Quebec, and at Bergen Point, N. J. His experience in the metallurgy of copper bore legitimate fruit in the publication at a later period of his first book, Copper-Smelting; but before this appeared (in 1885) he had already become known through his technical papers as an acute observer and reasoner, by no means averse to friendly controversy.

"Since it is my present duty to offer not so much a symmetrical and complete account of Professor Howe's activities as a description of the particular labors in recognition of which he receives today from his brother engineers the John Fritz gold medal, I shall pass lightly over the general features of his career, merely observing that from 1883 to 1897 he resided at Boston, and, besides his private practice as a consulting metallurgist and expert witness in metallurgical patent suits, was lecturer on metallurgy at the Massachusetts Institute of Technology; that in 1897 he was called to the professorship of metallurgy in Columbia University, from which position he retired in 1913 with the title of Professor Emeritus; and that for the last ten years he has declined as far as practicable all professional business, in order to devote himself exclusively to the completion of what had clearly become the great scientific mission of his life. To this end, he has maintained at his own expense a special laboratory of research.

"It gives me pleasure to fancy, whether or no the fancy be also fact, that I remember the beginning of that mission, forty-odd years ago. In 1871, the first year of the existence of the American Institute of Mining Engineers, Mr. Howe, then just graduated from the Massachusetts Institute of Technology, became a member of the new organization. His two earliest contributions to its Transactions, Blast-Furnace Economy, in Vol. III, and Thoughts on the Thermic Curves of

Blast Furnaces in Vol. V, indicated already that he was making a scientific study of practice. But between the dates of these papers a famous controversy was inaugurated in the forum of the Institute by the brilliant paper of Alexander L. Holley, *primus inter pares*, entitled What Is Steel? In this controversy, eminent metallurgists like Wedding, chemists like Prime, and expert captains of industry like Metcalf, vigorously took part; but of all the knights in the tourney, none rode a straighter course or laid in rest a sharper lance than Howe, whose paper on The Nomenclature of Iron ardently advocated a scientific as distinguished from a commercial nomenclature. To tell the truth, the battle had a commercial origin. The real question at issue was not, What *is* steel? but, What may fairly be called steel at the custom house? And the technical reputation of the Institute was invoked by one party in favor of a convenient, practical, industrial classification which would relieve importers from the expensive refinements of science.

"Well, there was even an international committee on the subject, and the committee made a report, and the report was not adopted by the Institute, except provisionally for optional use in its publications, because the Institute was wisely deemed to be an arena of discussions and not a tribunal of decisions. Never was a more fortunate position assumed, for the great question was left open, as it should be always. The tariff difficulty was adjusted somehow; the antagonists shook hands; the thunder of the captains of industry and the shoutings died away. But one man continued the inquiry fiercely in his own soul. Henry Marion Howe, before whom the dust of the controversy loomed like a giant Afrite still defying attack, devoted his life thenceforward to the mighty conundrum, What is steel? That he has spoken the last word—even his own last word—on the subject, no one would venture to say; but certain it is that he has brought us to a degree of knowledge the very existence of which was scarcely dreamed in 1876.

"It is curious that at that time he insisted upon the capacity of steel for hardening as an essential element in classification. For it was through this door—the study of the conditions and nature of the hardening process—that the advance was to be made into the wider field of knowledge. And the instrument of knowledge was to be the new science of metallography.

"That science, at least so far as it relates to iron and steel, may be said to have begun with the observations of Sorby on the microstructure of iron, reported in 1864 and 1868. Martens published independently in 1878. But already in 1868, Tschernoff had enunciated the chief laws which govern the metallography of iron. These were supplemented by the appearance in *Stahl und Eisen*, 1885, of Brinell's laws. All these creditable steps of progress were rendered more or less uncertain and incomplete by the imperfection of the apparatus and methods of precision, by consequent errors of observation, and by gaps in the data—though the aggregate quantity of material was already overwhelming. Then came in 1887 and subsequent years the remarkable investigations and intuitions of Floris Osmond, who discovered that metals frequently combine to form definite chemical compounds, and that these compounds frequently form solid solutions. He discovered also the thermal critical points of iron, and, interpreting these changes in the cooling curve as indications of some molecular change, propounded the brilliant hypothesis of the allotropy of iron which furnished the acceptable allotropic theory of the hardening of steel. To him, as Professor Sauveur remarks in his Biographical Notice of Osmond (Trans. A.I.M.E. xlv, p. 274), we owe likewise the discovery of austenite, the non-magnetic solid solution of iron and carbon existing above the thermal critical range, and the transition constituents, martensite, troostite and sorbite, marking as many distinct and important steps in the transformation, on cooling, of the solid solution austenite into the ferrite-cementite aggregate.

"This brings us to the date of Howe's first book on the subject; and the history of the new science, as I have already sketched it in general terms, is epitomized in the essays and books of Professor Howe from the appearance of his Metallurgy of Steel in 1888 to that of his Metallography of Steel and Cast Iron in 1916. The first of these books was an amazing accumulation of reported facts, tabulated, verified and explained as far as was then practicable. The last is an equally amazing array of facts, but now sifted, tested, logically arranged and luminously interpreted, exhibiting not uncomprehended differences, but significant similarities and relationships. The first was a heap, parts of which had been sorted; the last is an edifice. To produce the first required intelligent and inexhaustible industry and critical discernment. The second exhibits the creative genius of an architect. Between the two lies the history of a science, to every stage of which this builder has made some important contribution. Let me mention a few of these, under the heads of invention of improved methods; discovery of new facts; testing of data; and correlation and interpretation of observed phenomena. I shall not pretend to comprehensive completeness in this survey. I must be content with the exhibition of typical samples.

"One of the new methods invented by Professor Howe is that of determining the microstructural and other conditions which exist in steel at high temperatures by fixing those conditions through the process of quenching—a method which has been generally adopted, and by the use of which much clearer and more trustworthy results have been obtained than were formerly possible.

"Among his discoveries of new facts may be mentioned the isotropy of the effects of plastic deformation (announced in 1888, and supported in 1914); the possibility of effacing blowholes in soft steel by welding (1909); the relations of graphite flakes in cast iron, representing, not complete discontinuities of the metal, but only the filling by graphite of the interstices in ferrite skeletons; and the crystallography of the slip planes (Metallography of Steel and Cast-iron, p. 327).

"But this investigator kept himself acquainted with the discoveries of others. In 1893 he confirmed by rigorous experimental proof the brilliant hypothesis of Osmond that the transformations in steel represent the alternate acquisition and loss of hardening capacity.

"Under the head of testing and verifying data, I would name the rigorous analysis of the so-called Clapp-Griffiths process; the demonstration that the chief benefit of rolling and forging is due to the low finishing temperature rather than to the degree of mechanical reduction, as formerly believed; and the striking demonstration that the results of one of the most important investigations of the gas evolved from iron were wholly vitiated by the leakage of the apparatus. All these may be found in the Metallurgy of Steel, which contains also analyses of the conditions of dephosphorization, of the chemistry of the crucible process, and of the technique of Bessemer practice.

"In a remarkable paper on the structure of steel, contributed to the proceedings of the American Society for Testing Materials for 1911, Professor Howe collected into the

form of propositions or laws the observed relations of heat treatment to the microstructure and mechanical properties of steel. In that paper he enunciated twenty-three of these laws; and had he then ceased from his labors, his work would have followed him as an imperishable record indelibly carved upon the history of science. But he was destined to go still further during the five years which followed. His latest book, The Metallography of Steel and Cast-iron, published in 1916, occupies intellectually a higher plane than its predecessors, by which I mean that it commands a wider outlook, permitting grander generalizations, and the recognition, in due perspective, of causes, effects and relations. This book, in short, exhibits that simplification which I have described as following the stage of maximum complexity in the development of a science. Its very title, coupling steel with cast iron, expresses the maturer view which includes both in one continuous series, subject to the same laws—a significant conclusion of the controversy which began with the contention that steel was not cast iron. Not that the difference has been disproved but that a higher unity has been shown to embrace it. Such is indeed the normal end of controversy—'peace without victory' through agreement on a higher level.

"This book is not a textbook, repeating what is generally accepted already. Covering the field in which others have meritoriously labored, it propounds, suggests and prophesies new truth and new views of truth. It is a product of the two kinds of genius, the genius which consists in an infinite capacity for taking pains, and the genius which with happy intuition surveys, divines, coördinates and interprets the cosmos in the chaos.

"That my estimate of the work of our great American colleague, as summed up and set forth in this book, is not merely an expression of personal affection or patriotic pride, let me prove by one or two opinions from eminent authorities.

"I would quote first a few paragraphs translated from a review of the book by Professor Le Chatelier in the *Revue de Metallurgie* (Vol. xiii, No. 2, March-April, 1916):

> The new work of Mr. Howe is entirely original. It has nothing in common with the numerous treatises on metallography which have appeared during the last ten years. Whoever has read one of them has read them all. Here we have to do with the personal observations and views of the author. As he indicates in his preface, he has written this treatise, not to state the solidly established principles of a young science, but to cause the creators of that science themselves to think; to open before them new horizons. Hence he has not feared to announce theories sometimes a little hazardous. . . .
>
> This study will make an epoch in the history of the progress of science. It represents many years of uninterrupted research, but for a much longer period it will certainly be consulted by investigators with fruitful results.

"The following remarks are taken from a similar review by H. C. H. Carpenter, Professor of Metallurgy at the Royal School of Mines, South Kensington, England:

> It is quite safe to say that Professor Howe's book will at once take its place as an authoritative, and indeed, classical, exposition of the field of knowledge with which it deals. From whatever standpoint it is judged, it is a great book—great in its power, lucidity, balance, comprehensiveness, and preëminently scientific character.

"In a private letter, written with reference to the announcement that the John Fritz medal was to be conferred upon Professor Howe, the same distinguished author says that he believes no award could have given greater pleasure to the metallurgists of Great Britain, who look upon Professor Howe not merely as the *doyen* of metallographists in America but as their most distinguished representative; 'a worker whose single-mindedness in the pursuit of truth is an example to us all, and whose conscientiousness gives to his publications a character of their own.'

"Finally, I take the liberty of quoting from a private letter received by me from a no less eminent American, Prof. Albert Sauveur himself, who, as the President of the Board of Award, bestows this medal tonight:

> Professor Howe, in his recent masterly book on The Metallography of Steel and Cast-iron reviews exhaustively and examines critically, as he alone can do, every view at all worthy of recognition, dealing with the subject he covers. I believe that any responsible author who has ever expressed a reasonable opinion on any subject dealing with the metallography of iron and steel will find his views recorded and discussed in this book. Professor Howe then proceeds to weigh with great fairness and extraordinary intelligence and lucidity the arguments or evidence supporting the different views, and draws his conclusions accordingly. His method is that of a mathematician solving a problem in which each factor is given its proper value. In this way, Howe has rendered to metallurgists an inestimable service; and he alone could render it. Where most of us could see only chaos and obscurity, he is able to bring order, and to discover the light that, under his skillful manipulation, soon illuminates the darkest corners. . . .
>
> This, I think, is his greatest achievement—the marvellous coördination which he has brought into the science of metallography through his genius and his labor, tremendous in quantity, marvelous in lucidity. To him more than to any one else we owe the quick rejection of weak or ill-supported theories in favor of the survival of the fittest—a process so necessary to the advance of any branch of human knowledge.

"To these expressions of individual and representative opinion should be added the numerous formal honors bestowed upon Professor Howe by institutions and governments in many lands. England, France and Russia have each conferred three of these recognitions, while others have come from Germany and Sweden. And, last but by no means least to his patriotic heart, come two announcements, received since I began the preparation of this address, the one, of his election as a member of our National Academy of Sciences; the other, of his selection as one of the charter members enumerated in the proposed Act of Congress incorporating the American Academy of Engineers.

"Thus the applause of two continents attends the act of the John Fritz Medal Committee in selecting Henry Marion Howe as a recipient of that great honor. And the act has also another significance. It is a recognition on the part of engineers that the microscope and the test tube have become the tools of engineering. Indeed, when we remember that the strength of materials is the alphabet of every branch of engineering science represented by the givers of this medal, we must admit that the man who with microscope and test tube analyzes the causes and determines the conditions of that strength is among the greatest of engineers.

"While this testimonial is bestowed by engineers, I cannot forbear to utter my satisfaction that it is received by one who is more even than an engineer; whose many-sided patriotic and literary activity is typical of this age, in which engineers are, as St. Paul said of the Gentiles, 'no more strangers and foreigners, but fellow-citizens with the saints.' If we may say of him, as Johnson said of Goldsmith, '*non tetigit quod non adornavit*,' we may almost add, '*non est, quod non tetigit*.'

"And so we crown to-day with grateful pride, not only the leader, but also the comrade and friend!"

DR. HOLLIS EULOGIZES THE RECIPIENT OF THE MEDAL

Expressing his opinion that the spirit of the meeting should lead us to a new dedication of ourselves to the service of mankind, Dr. Hollis said: "It is not only a privilege, but also

an honor, to have a share in the award of the John Fritz Medal to Henry Marion Howe for his contributions to applied science. This medal as a recognition of achievement in applied science has completely justified itself if it has served no other purpose than to record in this admirable way the practical service to science. But it does more in calling attention to the great value of research. The popular conception of invention as a mere happy guess or thought has led many into a totally false conception of the method by which applied science has grown. As a matter of fact, practically all of our advancements have been the results of patient study and research, the work of developing a thought always being the harder and better part of it. In calling attention to the method by which Mr. Howe's great work has been accomplished, this meeting serves to educate and to clear the popular mind on the true value of scientific research and of the abstract study of all science. Not one of the recipients of the John Fritz Medal has earned his right to distinction by mere thought. Each one of them has worked, and worked steadily through his life, with some definite end in view, usually without much thought of the money side of his discovery. In this respect Mr. Howe is a worthy successor of all those who have preceded him on this honorable list. His work has been done quietly and modestly without the help from daily papers that has become so disturbing and, in some cases, so disastrous a part of the scientist's achievement in these later years. He is not only a fitting successor to all the men who have received the same honor, but he is also beyond all others of the same family as John Fritz. No professional man has ever earned lasting fame who has not obtained it through the high respect of those in his own profession. It is not the printing press and the public who make the reputation of a great man, but rather his companions in the profession who understand his work. Mr. Howe is thus singularly happy in the friends who have gathered around him tonight to rejoice with him. They will remember and understand well what he has done for the science of metals and for his country as well. As a teacher, a writer, and a scientist, his life is a speaking example of science wisely and unselfishly used in man's service. He has given and published freely his discoveries and his ideas on steel so that all his fellow citizens might benefit alike. There has been no touch of the baneful search for power through money. Without being an announced leader in scientific management, his work in teaching the industries the value of special steels, in adapting the means to the end, has been a great contribution to safety and efficiency.

"He has pointed out the path. Sometimes by simply indicating where the path enters the unknown, a teacher opens the way and leads others from traditional methods to new and better things. Life is made up of wandering pathways, and some great pathfinder stands at every parting. James Watt was at the beginning of modern industry, George Corliss at the first great departure in the economical use of steam, John Fritz lived to see his work culminate in the great Bethlehem Company. All the others on the list of medalists have found themselves at the beginning of an era in their subjects and now Henry Howe joins these immortals who have stood as the great teachers and pathfinders of mankind.

"Nothing that I can say here will add to his reputation. That is written in his books. This great meeting should, however, lead us to a new dedication of ourselves to the kind of service so much needed toward the rational life of man of this planet.

"Science has three aspects: first, to discover truth and follow it; second, to employ the forces and materials of nature for the good of all mankind; third, to set us into closer accord with the will of God.

"It is not necessary to dwell on these, except perhaps the last, which is the only pure science that we have. In these days of struggle for power, in these days when the white races are using their scientific knowledge to weaken one another, to destroy one another, it is well for us to search our hearts for those things in which science has been found wanting. At times we have made a god of it, with the thought that it alone has brought the human race out of darkness, that it has dispelled the shadow of superstition, and by promoting the well-being of man it has formed a true civilization. We sometimes forget that no civilization can continue to exist in an unbalanced condition. Science alone would make of this a hard, cold world, just as all intellectuality without heart tends to mere machinery. There are always two sides to a shield. Well-being and comfort without the spirit of self-sacrifice destroy rather than promote an enlightened civilization. It is well, therefore, on an occasion like this to give some thought to the religious side of life, and by religious I mean that kindly spirit brought into the world by Jesus Christ 1900 years ago. Nothing that the world has done or that science has produced is comparable with His one precept as the chief motive by which men can live. We may consider this great struggle going on in Europe, into which we ourselves are plunging, as the greatest thing that ever happened in this world, and yet it is insignificant by the side of that appealing life that ended on the cross so many centuries ago. 'Love thy neighbor as thyself' is the best inheritance of the race, as it is the chief hope of the future. Science is valuable only in so far as it vitalizes and strengthens that one principle, because we care nothing for new inventions, we care nothing for the comfort of men, and we care still less for the possible support of a greater population, if the soul be dead. Only so far as science promotes true democracy (not political democracy) and that love of men which will make wars impossible and eventually turn the lawyers into farmers is it worth while. In 1900 years it has done something toward making possible Christ's reign on earth. The famine areas of the earth have been reduced by the development of transportation and the communication by telegraph. Where there is a shortage of crops, we can quickly rush aid and supplies, and the world is generally willing to give a small percentage of its gain. It has remained for science to develop the most effective method of destroying the whole yield of a harvest, and plunge it into the bottom of the sea, so that it is only just to say that the human race has developed no international conscience. The organization for relief is still in its infancy, and there is only enough Christianity left to provide help more or less spasmodically. Another direction in which science has promoted Christianity is in preventive medicine, and in hospitals that have been established for all kinds of infectious and inherited diseases.

"But, after all, we have just touched the fringes of a real civilization, in which righteousness will be the guiding principle for nations, as well as for men. When the best minds are devoting themselves to the invention and construction of machinery and chemicals for killing men on a great scale, we are very far from loving our neighbors as ourselves. Science has therefore done as much to enslave as to emancipate, and we have not yet learned that its votaries are worshipping only half of the truth. Unless the engineer and those who profit through his work can be brought to realize that everything produced through science is held in trust for humanity, we shall make no progress. Our country will be plunged more and more into that

lethargic, luxurious state which can be cured only by the shedding of blood. Already we feel in this war a certain impulse of regeneration, and we need it. Our country has been called 'dollar mad' by Europe. Almost everything is judged from the one single basis of money. A book is good only if it sells. Fortunately there is one place into which this surrender has not penetrated: that is the teaching profession, and Mr. Howe's life well illustrates the kind of altruism that will bring us a happy regeneration, and a more lasting peace than we shall ever get through the blood of war. A better democracy must come through science. Men must learn to be ashamed to accumulate wealth through invention. No privilege by birth and no inheritance through the patent office should stain our democracy. No king can love his neighbor as himself, no great land owner who has the peasant on his farm can ever feel that the creature who toils is exactly like himself. This great war then is a war against false doctrine. Its end must be that greater democracy which teaches men unselfish service to one another, without which the race is not worthy to remain, and without which it ought to disappear. Only so far as science strengthens righteousness will it contribute to the great task before us as a free people.

"We see some signs in our country of a true enlightenment. The wealthy desire to give. Our privately owned colleges and schools are supported in large part by generous men who believe that their wealth is a public trust. It is only a gleam of light, however, for the percentage of giving is extremely small, and our problem will not be solved until we attain that enlightenment which makes it a duty for every man to give. We must think of invention and science and wealth as the mere instruments through which the individual is enabled to benefit the race. It is important that we should consider this whole question now, because the treaty of peace that must eventually come will ask for an answer. Science and Christianity must join hands to find some means by which the problem of a larger life can be solved between nations, as between individuals.

"Our profession has an ethical purpose, and it will fail if it does not see clearly that its place is not with science alone. Under various names it has been the one great constructive profession since reason began to develop in the creatures on this earth. Its history is practically the history of the human race. The political struggles have but recorded the advance of science in one form or another. To us as a profession, therefore, is confided the great task of enabling men to live on this planet under the theory that the highest happiness is attained through love, rather than through force. Organization is a science, as important as the machine. Life itself is the greatest of sciences. We must contribute our share.

"My chief reason for dwelling on the moral aspect of science, especially on that side of it which promotes the practical application, is that Mr. Howe's career well illustrates the motive that must always lie behind the engineer's work, if our profession is to live and to be found worthy."

PROFESSOR SAUVEUR THEN PRESENTS THE MEDAL. ADDRESS OF PROFESSOR SAUVEUR

Professor Sauveur made a brief introductory allusion to the municipal reception of the French mission, at that moment taking place at the Public Library. He thought it a happy coincidence, in view of Professor Howe's early, earnest and persistent advocacy in public and private of the cause of the Entente Allies. Then, turning to the subject of the evening, he continued: "After what you have heard there can be no doubt left—if any doubt ever existed—in anyone's mind as to the wisdom and discrimination exercised by the John Fritz Medal Board of Award in selecting its medalist for 1917.

"There is nothing that I could add to what has been so ably—yea, so brilliantly—told by Dr. Raymond. To me, however, as Chairman of this Board at the time the award was made, is assigned the delightful duty of actually presenting the John Fritz Medal to Professor Howe.

"Henry Marion Howe, son of an illustrious father and of an illustrious mother,

Lover of justice and of humanity,

Public servant and public benefactor,

Master of the English language,

Loyal and devoted friend,

Untiring and unselfish worker in an important field of science,

Stimulating teacher, inspiring investigator and generous collaborator, hundreds have been guided by the light radiating from your pen, encouraged by your kind words, dazzled it is true, but also stirred to further and more vigorous efforts by the heights you reach,

Voyager in realms but dimly perceived by your fellow-workers,

Lone explorer of fields destined to yield rich harvest to future generations,

Man of genius, honored and loved the world over,

By authority of the Board of Award, I now place in your hands the John Fritz Medal."

REPLY OF PROFESSOR HOWE

"It is not to me but to the bright unbodied image which you have created, to the foster child of your chivalry and your leniency, that these more than generous words apply, that this noble memorial is due. I thank you from the bottom of my heart on his behalf, while on my own I thank you as warmly for his acquaintance, for the hope that it may kindle into an inspiring friendship, letting me 'grapple him to my soul with hooks of steel,' and above all for this incitement to further and vigorous striving, holding with Ulysses that

> 'Old age hath yet his honor and his toil;
> ————————something ere the end,
> 'Some work of noble note may yet be done.'

"To prolong thanks is so thankless that I might well now hold my peace were it not for the world crisis, ever in our consciousness. This so presses for our best thought that attention to other matters suggests fiddling while Rome burns. For Rome truly is in flames. We are as a family in a burning home. Democracy itself is at stake.

"This conflagration should arouse Americans all the more because it is a necessary and integral part of the train of events which our forefathers started when those

> 'embattled farmers stood,
> And fired the shot heard around the world.'

"In that shot was stored the whole process of the liberation of man, including today's tragedy, as surely as the history of the oak, its growth, its majesty, and its fall, are stored in the acorn. The example of our freedom not only incited the more plastic peoples to democratization as in France and Britain, but also started a process of selection leading straight to this death grapple between democracy and autocracy. For by selection those most impatient of despotic control, those of greatest initiative, in short the most independent from all other

lands, emigrated to us and to the other democracies induced by our example, leaving as a residuum the less independent, the more docile.

"The democratizing impulse of our example, aided as it was in France by hunger and by outraged manhood, and in England by royal fatuity, was irresistible. But in Prussia it was so far weakened by material comfort created by the skill and craft of her kings that it failed, and in failing exaggerated this process of selection.

"That failure found the Teutons without those influences which in France and Great Britain temper the selection by emigration, the inborn domesticity of the French, and the closeness of the ties between Britain and her colonies, which leads great numbers of her sons to send their children back to school, and to return to the motherland later in life when their adventurousness has spent itself, thus restoring to the nation much of its more adventurous blood which the dreams of youth send abroad. Because Germany was intensely autocratic and without hope of democratization, she lost by emigration not only the most adventurous and independent, but even a vast number of those of intermediate independence, to our great gain. Thus the mean docility of the residuum was exaggerated. Because Germany lacked colonies these emigrants identified themselves with the countries to which they went, and renounced allegiance to their land of birth, so that the submissiveness of those left at home was undiluted by the return in later life of the more independent stock.

"It is this exaggerated docility, resulting thus irresistibly from the selection started by our liberation, that has led to this terrible struggle. For it has enabled the Hohenzollerns and Hapsburgs, through their Nietzsches and their Treitschkes, through a cunningly devised state education appealing to all the baser motives, to ensnare the Teutons, drunk with vanity and new riches, in the intellectual slavery implied by their adopting the monstrous doctrine that might makes right, with all its sickening corollaries, its frightfulness, its foulness, and its treachery,

> 'hideous as the deeds
> Which you can scarce hide from men's revolted eyes.'

"It is this docility, with the resultant intellectual enslavement, that has enabled these autocrats to weld their people into a mass so coherent, so blindly unquestioning, as to strike with an initial force wholly disproportionate to their numbers when compared with those of democracies, whose units, however strong individually, cohere but feebly in every-day life because of their individualism.

"It is this frightfulness, it is this depth of depravity and cruelty engrafted on all Teutonia through this same process, that has added incalculably to the danger that autocracy will win, by frightening into neutrality or even into ill-concealed coöperation Germany's small neighbors who are our natural allies. Such a victory, leaving the Hohenzollerns and Hapsburgs still in power, could at best be followed by a truce between two armed camps, autocracy and democracy, during which the world would be putting all its available energies into arming for a renewal of fighting.

"Slow as we have been to understand that this struggle is something more than the latest of the European wrangles 'whose obscure sources do not interest us,' once we let our eyes be opened, once we saw that a great moral principle was at stake, we resolved that as it was we who had begun the extirpation of autocracy, so we must share in carrying this work to its triumphant end, not because any other course might well leave us to fight Teutonia singlehanded but because we are determined that 'government of the people, by the people, for the people shall not perish from the earth.'

"Our efforts should be quickened by the thoughts that though the means of creating men cannot in the nature of the case be hastened, those of destroying men can be accelerated to an indefinite degree by the applications of science. The very qualities which have enabled man to better himself at a rapidly accelerating rate by his inventions, the steam engine, anesthesia, the sewing machine, the motor car, the telegraph, the telephone, and wireless telegraphy, are capable of being used to increase at an equally accelerating rate the means of slaying him. From the enormous increase in the powers of human destruction in the few decades since Sedan we get but a first foretaste of what man is inherently capable of inventing. We are indeed shocked at the new and higher order of destructiveness of this war, but our imagination fairly reels in trying to conceive the still higher order of ruin of future wars, should autocracy stay in the saddle. Those against whom this enhanced destruction, this annihilation, would be launched would not be the savage and uncivilized but the very flower of the race, those who threaten autocracy most. Because man cannot deprive his fellows of these powers of invention, he can prevent his own annihilation only by curbing autocracy, that form of government which evolves naturally through human destruction, or better by destroying it and replacing it with democracy, which evolves naturally through human betterment.

"Our problem at the end of the war will be to prevent future wars, to prevent the actual employment of the enormously enhanced destructive powers sure to evolve, to force the nations to keep the peace as we have forced individuals. To say that we are inherently incapable of preventing our own annihilation; that because the less developed past did not learn to prevent its little wars, killing their tens of thousands, the more developed future must ever remain impotent to prevent its wars with their far higher order of havoc, killing their millions, is to betray a fatalism, a pessimism as unworthy of Americans as it is foreign to our nature. To me it seems an insult to the mothers who bore us, nay, to the God who made us."

Volume 38 of Transactions

The thirty-eighth annual volume of TRANSACTIONS of The American Society of Mechanical Engineers is now off the press and will shortly be placed in the hands of the membership. The volume records the affairs of the Society during the year 1916, and includes the annual report of the Council, giving a résumé of the activities of standing and special committees, and a calendar of the 103 general and local meetings held during this period. It also contains, under 46 titles, all the papers and discussions presented at the Spring Meeting, held in New Orleans in April 1916, and at the Annual Meeting, held in New York in December 1916. The papers deal with industrial management, the appraisal and valuation of industrial property, power-plant equipment and operation, the measurement of flow of air, natural gas, steam and water, drainage pumping, hoisting and handling machinery, balancing, vibration in mill buildings, machine-tool standardization, gas producers, steam and electric locomotives, electric boiler-joint welding, etc. A Code of Safety Standards for Cranes, prepared by the Sub-Committee on Protection of Industrial Workers, is presented. Credit for these papers should be given to the Committee on Meetings, its Sub-Committees, and the Sections Committees, through whom they were secured.

Standardization of Machine-Screw Nuts

On June 8, our Society and the Society of Automotive Engineers received a request from the Navy Department to consider the standardization of machine-screw nuts. This request was embodied in the following letter from Naval Constructor D. W. Taylor:

NAVY DEPARTMENT

BUREAU OF CONSTRUCTION AND REPAIR
WASHINGTON, D. C.

Mr. Calvin W. Rice, Secretary,
The American Society of Mechanical Engineers,
29 West 39th Street, New York City.

Dear Sir:

The Bureau's attention has recently been directed to the fact that paragraph 8 of Navy Department specifications 42S5b specifies dimensions of machine-screw nuts which prohibit the supply of such material by other than a limited number of manufacturers. Upon investigating the question, the Bureau has been impressed with the fact that there are apparently no standardized widths and thicknesses; brass and iron, hexagon and square nuts supplied by different manufacturers vary considerably in such dimensions for the same nut number. Seven manufacturers of this material have furnished the Bureau dimensions of the nuts they make; these requirements have been tabulated in the blueprints attached hereto. The last column in each of the blueprints contains the sizes as at present appearing in paragraph 8 of Navy Department specifications 42S5b.

It would appear that it would be desirable for The American Society of Mechanical Engineers or the Society of Automotive Engineers to undertake to standardize the dimensions of machine-screw nuts, if such work, in fact, has not already been inaugurated. It is felt that the elements involved in the investigation, such as any desirable relation of the width or outside diameter of nuts to the diameter of washers, the relation between the thicknesses of nuts and the usual commercial thicknesses as rolled of sheet brass or sheet steel, etc., can better be handled by you or a similar national society than by the Bureau. A letter similar to this is, therefore, being addressed to the Society of Automotive Engineers.

The Bureau desires to express its interest in the problem, its willingness to coöperate in any way practicable, and would appreciate your comments relative to the question at issue.

Respectfully,
(*Signed*) D. W. Taylor,
Chief Constructor, U. S. N.,
Chief of Bureau.

After conference with the Society of Automotive Engineers, the Society accepted the duty and addressed the following reply to the Navy Department, and President Hollis appointed E. H. Ehrman, E. Burdsall and Charles Glover as a committee to coöperate with the S. A. E. Committee, consisting of E. H. Ehrman, chairman; Clarence Carson, E. S. Crawford, J. E. Diamond, W. H. Nolls, Berne Nadell, H. H. Newson and E. E. Sweet.

Rear-Admiral D. W. Taylor, Chief Constructor, U. S. N.,
Chief of the Bureau of Construction and Repair,
Washington, D. C.

Dear Sir:

We accept cheerfully the request to standardize machine-screw nuts, and will immediately appoint a committee and coöperate with the Society of Automotive Engineers.

Yours truly,
(*Signed*) Calvin W. Rice,
Secretary.

The Navy Department acknowledged the offer of the two societies in the following letter:

NAVY DEPARTMENT

BUREAU OF CONSTRUCTION AND REPAIR
WASHINGTON, D. C.

The American Society of Mechanical Engineers,
29 West 39th Street, New York City.

Gentlemen:

The Bureau is pleased to note from The American Society of Mechanical Engineers' letter of the 9th instant, and the Society of Automotive Engineers' telegrams of the 11th and 12th instant, that the suggestion offered in the Bureau's letter that work be inaugurated in the standardization of dimensions of machine-screw nuts has been adopted. It is furthermore noted that The American Society of Mechanical Engineers and the Society of Automotive Engineers are coöperating in this problem. The Bureau is gratified indeed at the prompt response accorded the question in hand.

You will be communicated with at a later date relative to the Bureau's representative in connection with the subject at issue. It is felt that the question to be investigated is of interest not alone to this Bureau, but also to one, and possibly two, other Bureaus concerned with the suggestion that representatives be nominated to coöperate with The American Society of Mechanical Engineers and the Society of Automotive Engineers. The Bureau also feels that it will be highly desirable to have representatives of the Army and the Bureau of Standards on the Committee; it would be better, however, to have your organizations communicate with those branches of the Government direct as to any representatives which each branch might desire to nominate.

Respectfully,
(*Signed*) B. Stocker, *Acting*
Chief Constructor, U. S. N.,
Chief of Bureau.

The joint committee met in Washington on June 23, and the Navy Department was represented by Naval Constructor J. A. Furer, U. S. N.; the Bureau of Standards was represented by Mr. L. A. Fischer, and the Aircraft Engineering Board by Mr. C. B. King.

At this first meeting a table of proposed machine-screw nut dimensions was formulated to be sent to all manufacturers of such nuts for their criticism and suggestions.

The Bureau of Ordnance of the Navy Department has nominated W. W. Smyth as its representative on this committee.

Engineering Council

At the organization meeting of the Engineering Council, held in the rooms of The American Society of Mechanical Engineers, on June 27, the following officers were elected: President, I. N. Hollis; vice-presidents, H. W. Buck, George F. Swain; secretary, Calvert Townley. Executive Committee: Those named, with J. Parke Channing and D. S. Jacobus.

The council discussed at length ways and means by which the founder societies through the council may be of use to the nation. The unanimous desire to help the Government in the prosecution of this war resulted in a resolution instructing the executive committee to coöperate with the Government in procuring the services of engineers, also in the appointment of a committee of three, consisting of Messrs. H. W. Buck, A. M. Greene, Jr., and Edmund B. Kirby, to consider the best means of utilizing the inventive ability of members of the founder societies.

The secretary was instructed to inform all Government bureaus that might be interested of the organization of the Engineering Council and of its desire to be of assistance.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER SEPTEMBER 10, 1917

THE American Society of Mechanical Engineers is an organization for mutual service of over 8100 engineers and associates coöperating with engineers. The membership of the Society comprises Honorary Members, Members, Associates, Associate Members and Juniors, all elected by ballot of the Council. Application for membership is made on a regular form furnished by the Secretary which provides for a statement of the standing and professional experience of the applicant and requires references from voting members personally acquainted with the applicant. The requirements for admission to the various grades will be furnished upon request.

Below is the list of candidates who have filed applications for membership since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, and those in the third under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by September 10, 1917, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about October 15, 1917.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be somewhat slower than under normal conditions. The first step in the consideration of an application is taken by the Membership Committee, and this committee is composed of busy men, with fewer opportunities to meet together in these strenuous times.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Colorado

AKERLOW, CARL G. W., Engineer in Charge of Drafting and Designing, Colorado Iron Works Co., Denver

Connecticut

BREUL, FRED G., Owner and Manager, Private Manufacturing Business, Design and Construction Automatic Machinery, Bridgeport

DOYLE, BARTHOLOMEW M., Chief Engineer, Housatonic Power Co., Waterbury

District of Columbia

EICKHOFF, THEODORE H., Research in Ordnance Work, Washington

Indiana

HAMILTON, WILLIAM E., Efficiency Engineer, Premier Motor Corp., Indianapolis

Massachusetts

AFFLECK, BERTRAM L., Prevocational Instructor, City of Boston, School Department.

JUDGE, FRANKLIN, General Superintendent, Greenfield Tap & Die Corp., Greenfield

MACOMBER, CARLTON H., With General Electric Co., Lynn

POWELL, ALBERT M., Consulting Engineer, Powell Machine Co., Worcester

WHIPPLE, GEORGE F., Compiler "Catalogue Studies," Boston

Michigan

KREIDLER, DANA W., Chief Engineer, Carburetor Division, Detroit Lubricator Co., Detroit

PERRY, THOMAS D., Secretary, Grand Rapids Veneer Works, Grand Rapids

Mississippi

DROSS, PHILLIPP, Vice-President and General Manager, The Marty Foundry Co., Inc., Meridian

New Jersey

ACKERMAN, ALBERT A. JR., Chief Draftsman, The Singer Manufacturing Co., Elizabethport

HAGELTHORN, THOMAS, 436 Highland Avenue, Arlington

New York

COLLINS, EDGAR F., Engineer Industrial Heating, General Electric Co., Schenectady

DIAMANT, SIDNEY, President, De Mant Tool & Machine Co., New York

McCOY, WILLIAM T., Tool Department Head, Savage Arms Co., Utica

WILLIAMS, CHARLES S., Sales Engineer, American District Steam Co., North Tonawanda

Ohio

CAMM, JOHN A., Vice-President, The Cleveland Milling Machine Co., Cleveland

DOAN, JAMES B., President, The American Tool Works Co., Cincinnati

WESCHE, BJARNE A., Owner, B. A. Wesche Electric Co., Cincinnati

Pennsylvania

GLYNN, CHARLES V., Mechanical Engineer, Hershey Chocolate Co., Hershey

McBRIDE, JOHN J., Chief Export Inspection Bureau, American Car & Foundry Co., Berwick

Washington

WITHERSPOON, WILLIAM O., Designing Engineer, Washington Portland Cement Co., Concrete

West Virginia

JENKINS, EDWIN M., Mechanical Engineer, Virginian Railway Co., Princeton

Wisconsin

BREED, PRESTON H., formerly with National Brake & Electric Co., Milwaukee

KELLER, WILLIAM H., President and General Manager, Keller Pneumatic Tool Co., Fond Du Lac

Philippine Islands

STANTON, ROBERT B., JR., Manager Mechanical Engineering Department, Frank L. Strong Machinery Co., Manila

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

Connecticut

RATZKOFF, SILAS M., Production Superintendent, Gun Department, Winchester Repeating Arms Co., New Haven

New Jersey

McWILLIAMS, WILLIAM W., Assistant General Manager, Aeromarine Plane & Motor Co., Keyport

New York

HORN, HARRY P., Draftsman, General Acoustic Co., Jamaica, L. I.

ROBERTS, MORTIMER J., Sales Engineer, Air Reduction Co., New York

Ohio

ESTABROOK, CHARLES B., Manager, The Safety Ladder Co., Dayton

SPEAR, WALTER A., Test Engineer, Cincinnati Milling Machine Co., Cincinnati

Pennsylvania

LYONS, KARL M., Production Manager, Clarendon Refining Co., Clarendon

Vermont
BEAL, HENRY S., Manager of Cost Department, Jones & Lamson Machine Co., Springfield
Washington
GOFF, CLIFFORD, Machinist, U. S. Navy Yard, Puget Sound, Bremerton

FOR CONSIDERATION AS JUNIOR

Connecticut
ENGLEHART, RUSSELL J., With Winchester Repeating Arms Co., New Haven
PRYOR, WILLARD L., Assistant to Superintendent, Singer Manufacturing Co., Bridgeport
Illinois
ATZENHOFFER, ARTHUR H., Mechanical Engineer, Western Electric Co., Chicago
CLIFFORD, CHARLES H., JR., Industrial Engineer, Cooley & Marvin Co., Chicago
Kentucky
GRAY, HENRY C., Graduate Rose Polytechnic Institute, 1917, Resident Louisville
Maryland
MICHEL, RUDOLPH, Draftsman, Baltimore Oil Engine Co., Baltimore
TYSER, LEO, Superintendent Heating Division, Terminal Freezing & Heating Co., Baltimore
Massachusetts
BOLTON, WRIGHT JR., Master Mechanic, Acushnet Mills Corp., New Bedford
ELIN, MICHAEL B., Engineer, New England Westinghouse Co., Chicopee Falls
KNIGHT, EARL R., Assistant to the Superintendent on Production Work, Washburn Shops, Worcester Polytechnic Institute, Worcester
WARNER, EDWARD P., Assistant in Aeronautical Engineering, Massachusetts Institute of Technology, Cambridge
Michigan
OTIS, J. HAWLEY, Student, Mechanical Engineering, University of Michigan, Ann Arbor
Missouri
CHOCKLEY, FRED W., Chief Draftsman, Henrici Kent & Lowry Eng. Co., Kansas City
RENKEN, HARRY J., Traveling Representative Railroad Department, Fairbanks, Morse & Co., St. Louis
New Jersey
HARMON, WILLIAM C., JR., With Calco Chemical Co., Bound Brook
New York
FRIEDKIN, GEORGE, Mechanical and Radio Engineer Superintendent, Dubilier Condenser Co., Inc., New York
MACNABB, CLIFTON E., Sales Engineer, Worthington Pump & Machinery Corp., New York
PLONSKER, MAURICE J., Machine Designer, Lidgerwood Manufacturing Co., Brooklyn
SPERRY, SAMUEL E., JR., Draftsman, Interborough Rapid Transit Co., New York
THOMAS, OSCAR A., Ordnance Department, Inspector, New York Arsenal, Governors Island, New York
Ohio
BROCKMAN, BERNARD N., Special Representative, The R. K. Le Blond Machine Tool Co., Cincinnati
GIEBEL, ROBERT L., Production Engineer, Cincinnati Milling Machine Co., Cincinnati
MONAGHAN, WALTER I., Sales Engineer, Armstrong Cork & Insulation Co., Cincinnati
SOLLER, WALTER, Fellow Mechanical Engineer, University of Cincinnati, Cincinnati
Pennsylvania
CONNELL, F. VAN BUREN, Assistant Superintendent, The Baldwin Locomotive Works, Philadelphia

APPLICATION FOR CHANGE OF GRADING

PROMOTION FROM JUNIOR

Michigan
EMSWILER, JOHN E., Professor of Mechanical Engineering, University of Michigan, Ann Arbor

NECROLOGY

FRANK FIRMSTONE

Frank Firmstone was born in Glendon, Pa., on August 29, 1846, and received his early education at the Phillips School, Easton, Pa. From there he went to the Saunders Military Academy in Philadelphia, and in 1865 was graduated from the Polytechnic College of Pennsylvania as a mining engineer.

His first position was with his father in the Glendon Co., and he was associated with this firm for 21 years. Upon the death of his father in 1875 he became general manager of the company. He resigned in 1887 and soon after became associated with the Cranberry Iron & Coal Co., Cranberry, N. C. He was president of this company for a number of years and was a director of all its subsidiary companies until the time of his death.

He was a recognized authority on engineering matters, and contributed valuable papers on blast-furnace practice to the American Institute of Mining Engineers.

Mr. Firmstone was a member of the American Institute of Mining Engineers, the American Society of Civil Engineers, the American Society for Testing Materials, the American Forestry Association, and the Engineers' Club of New York.

He became a member of the Society in 1880. He died on June 27, 1917.

JAMES JOHNSON PEARD

James J. Peard was born in New York City on July 25, 1849, and was educated in the public schools of Hartford, Conn. He left school to enter the employ of Colt's Patent Fire Arms manufacturing Co., where he learned his trade.

In 1873 he went to Providence where he worked with the Providence Tool Co. and afterward with the Brown & Sharpe Manufacturing Co. In 1876 he became a contractor in the employ of the Remington Arms Co., Ilion, N. Y., and after remaining there five years returned to the Colt company at Hartford. In the employ of this firm he gradually worked up until he became assistant superintendent in 1888 and superintendent in 1902. He retained the latter position until 1911, when he retired because of ill health.

For twelve years Mr. Peard was a member of the Board of Education of Hartford, serving as its secretary and president. He was a member of the Colt Mutual Benefit Association, which he organized and of which he was president until 1914. He was the inventor of many improvements in the products of the Colt company and was a recognized authority on firearms.

He became a member of the Society in 1891. He died on July 3, 1917.

WALTER BEVERLY PEARSON

Walter B. Pearson was born in Madison, Wis., on Dec. 2, 1861. He spent his boyhood in Wisconsin and obtained his education there, completing it with two years spent in the University of Wisconsin, where he specialized in mechanics. Upon leaving the University he went to Cleveland, where he took a position with the Warner & Swasey Co.

He left this firm to become assistant superintendent of the

Prospect Machine and Engine Co., Cleveland, resigning in June 1888, [illegible] a position with the Kummer Engine Co. in Chicago, Illinois [illegible]. Later he worked in the same capacity for [illegible] & Co. [illegible] for the Ball Engine Co., both of Chicago.

In [illegible] he organized the Pearson Machine Co., [illegible] special machinery of his own invention and [illegible] in producing and selling machine-screw products manufactured on the Pearson automatic screw machines.

In 1900 the Pearson Machine Co. was acquired by the Standard Screw Co., and in 1901 Mr. Pearson became a director of the latter company and was made vice-president. In 1904 he was elected president. Under his able management the company grew in strength and importance, acquiring in this process a number of the smaller machine-screw companies.

Mr. Pearson was a member of many clubs and societies, including the Engineers' Club of New York and the Chicago Engineers' Club.

He became a member of the Society in 1886. He died in Chicago on May 19, 1917.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

POSITIONS AVAILABLE

In forwarding applications, stamps should be enclosed for transmittal to advertisers; applications for non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society. Copy for notices must be in hand by the 15th of the month.

ENGINEER, technical graduate preferred, experienced in the design of open feedwater heaters, softeners, etc. Good position to right person. Write fully, giving details of experience and references. 102.

INDUSTRIAL ENGINEER—COST ACCOUNTANT. A well-established firm can offer exceptional opportunities for effective and interesting work to engineering graduates who have had substantial experience with modern industrial accounting, with special reference to manufacturing costs. In reply state age, education, experience, present and expected salary. 431.

ELECTRICAL ENGINEER possessing extensive experience with electrolytic plants for producing oxygen and hydrogen, wanted by New York concern. 811.

HIGH-GRADE MAN having a technical training desired by company with factory in western Maryland in the capacity of assistant designer and works manager. Duties to assist in designing special machinery and developing ideas; analyze machine operations, prescribe equipment and devise means to effect speedy and economical production; superintend the manufacturing of such machinery. Requires the ability of a thoroughly practical master mechanic with original ideas as to methods, a knowledge of modern shop practice, familiarity with the design and application of time-saving fixtures, executive ability and diplomacy necessary to successfully direct a manufacturing plant. No question of salary if the right man applies. State full particulars and technical experience with the assurance that such information will be held as confidential and no investigation will be made with present employer prior to conference. 958.

DESIGNERS. Men experienced in steam-engine and turbine work preferred. 967.

DRAFTSMEN, technical graduates, familiar with design of power-station installations, steam piping and a fair amount of structural work. State age and experience. Location Brooklyn. 990.

DRAFTSMEN AND DESIGNERS. Expeerienced men with some knowledge of valves and fittings; good future with large concern. State experience in full, salary expected and references. Confidential. 1002.

DESIGNER, familiar with pumps, blowers, heating and ventilating systems, for concern in Rochester, N. Y. 1008.

YOUNG DRAFTSMAN required immediately by manufacturer of power-plant specialties. Must be technical graduate and have had shop experience. One familiar with feedwater heaters preferred. Exceptional opportunities to acquire knowledge of design and production. Rapid advancement. Location Pennsylvania. 1013.

DRAFTSMAN. Young engineer, preferably a technical graduate with about a year's practical experience, who could work into a good position. Salary, $25 to start. Location New York. 1080.

DRAFTSMEN desired by firm manufacturing railroad specialties. Location New York State. 1084.

YOUNG ENGINEERING SALESMAN, not over 28 years of age, on application of steam specialties. 1089.

OPERATING CHIEF ENGINEER in charge of paper mill—man thoroughly familiar with boiler plants who is capable of making study of furnace conditions and tests. Salary $2500 to $3000. Location New Haven, Conn. 1129.

ESTIMATING ENGINEER. Prefer to secure a man of such age as not to be likely to be drafted for military service. Position requires a fairly comprehensive knowledge of construction work, a thorough knowledge of pumping machinery, piping and preferably concrete work, also qualifications that will enable a man to estimate on more or less complicated special machinery. Location New Jersey. 1130.

DRAFTSMEN experienced in ordnance work, particularly small arms and machine guns, or experienced in complicated automatic machinery. 1131.

COMBUSTION ENGINEER. Duties primarily those of efficiency work in the burning of fuel and generation of power, also in the use of power in the various departments of plant. Power plant is of 4000 hp. capacity, with extensive distributing system for air, steam and electricity. Excellent opening for a man interested in steam power-plant work. State fully qualifications, training and experience. Location New Jersey. 1133.

GRADUATE MECHANICAL ENGINEER with knowledge of centrifugal machinery—preferably fans, pumps and compressors—and also thoroughly familiar with their design and methods of testing same. Apply by letter. Location New York. 1140.

RECENT MECHANICAL ENGINEERING GRADUATES. Must have initiative and capacity for plenty of hard work in design, construction and operation of gasoline plants for large independent oil company. Location Oklahoma. Expenses paid. 1141.

MASTER MECHANICS, ASSISTANTS, INSPECTORS, ETC., in the construction and operation of a large shipyard. The organization must be completed as soon as possible. Location Pennsylvania. 1146.

SUPERINTENDENT OF CONSTRUCTION for mechanical equipment, including power plant, of hospital and medical college in Peking, China, for group of 14 buildings. Work will be installed by day labor and clients desire capable executive to act as superintendent for installation of such equipment. 1147.

1917 GRADUATE IN MECHANICAL OR ELECTRICAL ENGINEEERING for drafting and estimating work in connection with blast furnaces and mines. Location East Tennessee. 1152.

DRAFTSMAN for steel company. Position will be interesting, as there is a lot of new work started. Location New York State. 1153.

DRAFTSMAN. Work includes a wide range of designing machinery for roofing manufacture, conveying, foundations and plant layout. Location Perth Amboy, N. J. 1154.

DESIGNER, between 25 and 35 years of age, with mechanical and electrical engineering knowledge and sufficient shop experience to enable him to design apparatus so that it can be economically manufactured. Some pneumatic engineering experience desired, but not absolutely necessary. Work: improvement of present product in regard to increasing the quality of finished article. Design of new products now in process of development. Salary $1200 to $3000, depending entirely upon the man and his ability. Location Hoboken, N. J. 1155.

DRAFTSMAN on agricultural machinery for positions in either Porto Rico or Santo Domingo. Write fully stating age, experience, salary required and whether married or single. 1156.

SHOP SUPERINTENDENT for machine shop manufacturing planers, lathes, etc., and employing 200 to 300 men. Confidential. 1158.

GENERAL FACTORY EXECUTIVE. High-grade mechanical engineer wanted for position of works superintendent having direct charge of all power and maintenance work in a factory of over two thousand employees. Applicant must be able to show that he has made good previously in a similar position and must have pronounced executive and machine-designing ability. A desire to work harmoniously with organization a prime qualification. In first letter state age, salary and complete record of experience. Location, New York district. Permanent position for a real man. 1162.

COMPETENT MAN, about 35 years old, to take hold of maintenance and machine repairs and general shop economies. Prefer one who has had technical education and enough shop experience to understand the operation of all machine tools, and who has a full appreciation of the value of time in an operation without going into any efficiency work. Opportunity for advancement and eventually an executive position. 1166.

SALESMAN for mechanical apparatus. Salary depends on man. 1167.

DRAFTSMAN experienced in laying out dies. Permanent position. State previous experience and salary expected. Location New Jersey. 1170.

SALES ENGINEER for Spain desired by export house. Must be an experienced man who has actually sold machinery in that country. Must be competent to develop efficient sales organization, appoint sub-agents, etc. A substantial profit share will be paid in addition to salary, exceptional opportunity. Address applications in Spanish or English. 1172.

SALES ENGINEER for France desired by export house. Must be an experienced man who has actually sold machinery in that country. Must be competent to develop efficient sales organization, appoint sub-agents, etc. A substantial profit share will be paid in addition to salary, therefore an exceptional opportunity. Address application in French or English. 1173.

MECHANICAL ENGINEER familiar with general machinery in woodworking and machine shops to take charge of drafting room. Concern at present planning ship ways, and the work for this particular engineer will be the laying out of the woodworking shop and the machine shop, as well as derricks, cranes, etc. Location Pennsylvania. 1175.

INSPECTOR. Energetic, capable young man as inspector in plant manufacturing small machinery and machine parts. Should have had experience as a machinist. State initial salary expected, age, experience and qualifications. Good opportunity for advancement. Location New Jersey. 1183.

ENGINEER in drafting and engineering department. Able man with technical training wanted, familiar with structural work and machine design; conveying-machinery experience will be of advantage. Splendid future for right man. State fully particulars of education, experience, age, salary expected, etc. All letters regarded as confidential. 1185.

SALES ENGINEERS. Men of at least 24 years of age, with college education or its equivalent, who have had mechanical training and shop experience in the sales department of a prominent manufacturer of pneumatic machinery. Good opportunity for the right man. Give references, experience and salary expected. 1187.

DRAFTSMAN with sufficient experience to enable him to take charge of the making and checking of detail drawings in a drawing room employing two or three men. State qualifications and past experience fully. Large part of the work will consist of routine calculations. Applicants must be possessed of technical training. Salary about $150 per month. Location New York State. 1189.

FACTORY EXECUTIVE, technically trained, about 30 to 35 years of age, for large textile-machinery manufacturing plant. Knowledge of up-to-date shop methods essential, also successful experience in the handling of mechanics. Applicant would be required to spend from one to two years in shop to become familiar with the various classes of work, after which the position of assistant superintendent with further excellent opportunities for promotion will be open to him. Salary at start, about $2500. Location Mass. 1191.

ASSISTANT SUPERINTENDENT. Man about 30 years of age who has worked his way through a technical institution along mechanical or chemical lines. Duties partake of the nature of assistant superintendent without such official title. Position requires application and long hours, and affords inducement and opportunity for pay beyond the starting wage. Salary to start, about $25. Location Virginia. 1192.

YOUNG DRAFTSMAN. Location Jersey City, N. J. Salary $20. 1193.

YOUNG ENGINEER to work [illegible] report on shop efficiency. Salary $20. Location Jersey City, N. J. 1194.

TWO YOUNG ENGINEERS: One a recent graduate with some electrical-engineering training, at a salary of $[illegible] a month; the other with some experience in drafting-room work, salary $125 per month. Location, New York. 1197, 1198.

YOUNG DESIGNER on jigs and fixtures. Salary $125 to start. Prefer young man with some shop experience. Location New York. 2000.

YOUNG TECHNICAL ENGINEER for sales work on fans, blowers, turbines. Need not have had previous experience in sales line. Salary to start, $1500. 2001.

TOOL DESIGNERS capable of designing jigs and fixtures on machine-tool equipment from the piece-part drawings. None but first-class man will be considered. Salary $35 per week; transportation charges paid. Location Middle West. 2004.

EXPERIENCED TOOL DESIGNERS. Familiar with tools, jigs and fixtures for miscellaneous machine shop production work, including turbines, reduction gears, guns and gun carriages. Attractive offer to capable man. Location Maryland. 2006.

DESIGNER of centrifugal pumps capable of taking charge of department in established concern manufacturing pumps for special conditions. State age, experience and references. Location Pacific Coast—New York City conference. 2008.

MAN 30 to 35 years old, preferably with some experience along manufacturing lines and capable of working into responsible position in short time. Opening is with well-established concern in New England, manufacturing variety of metal articles and novelties. Give full details of education, experience, positions held, salary expected, etc. 2009.

DRAFTSMAN with at least five years' experience in the detail of machine parts. State age, experience, salary expected and give references. Position permanent. Location near New York City. 2012.

CHIEF DRAFTSMAN with executive and engineering ability, competent to direct the work of eight draftsmen and superintend design of output of plant manufacturing large tanks, steel mill buildings, zinc-smelter equipment and [illegible] work along engineering lines. Must be competent to operate system now installed in relation to [illegible] and ordering materials. Want man with at least ten years' experience in manufacturing lines. Salary $2000. Location Kansas. 2013.

MANUFACTURING COMPANY has openings and invites applications from men of engineering experience familiar with design of plate, mechanical and construction work. These openings offer permanent positions and exceptional opportunities for men who are competent to prepare drawings, write bills of materials and shop orders and requisition materials for this class of work. Salaries entirely contingent on ability to produce results. Location Kansas. 2014.

DRAFTSMAN for general design of new machinery and improvement of existing machinery in large [illegible] plant. Position leads to industrial management work. Write giving full particulars. Location Maine. 2016.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be in hand by the 15th of the month, and the form of the notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

INDUSTRIAL PLANT ENGINEER. Technical graduate, age 32. Nine years' experience in design, construction, operation and main-

[illegible] and power plants. Specialized in heating and [illegible] and drying of materials. H-269.

MECHANICAL AND ELECTRICAL ENGINEER of fifteen years' [illegible] and practical experience. Can design, supervise or organize [illegible] new work where initiative, tact or perseverance are required. Can [illegible] best professional and character references. Temperamentally qualified to adapt self to various personnel within or without [illegible] organization. At present employed but desires new connection where there is ample opportunity to produce results. H-270.

ASSISTANT OR ASSOCIATE PROFESSOR OF MECHANICAL ENGINEERING. Technical graduate, degrees of B.S. and M.E. Age 27, married. Two years' experience as assistant superintendent of manufacture with illuminating gas company, in charge of labor and mechanical equipment. Experience in drafting, heating and ventilation work and as assistant to a consulting engineer. Three years' experience teaching mechanical-engineering subjects. Desires position with a progressive college or university for the year beginning September 1, 1917. H-271.

MECHANICAL ENGINEER. Columbia graduate, age 37, married. Fourteen years' service in motive-power department of large western railroad, in testing laboratory, as draftsman, assistant engineer of tests and assistant mechanical engineer. Desires opportunity for advancement and greater responsibility. At present employed. H-272.

MECHANICAL ENGINEER. Technical graduate, with knowledge of Spanish and experience in power plant and sugar mill, desires position as manufacturer's representative, power-plant engineer, sugar-mill engineer or instructor in a technical school. H-273.

MECHANICAL ENGINEER, EXECUTIVE. Age 32, married. Ten years' experience. Aggressive and courageous, having an excellent record and many reliable references. At present employed as head of the engineering department of a large manufacturing firm. Would like position in engineering, production or sales department of commercial firm. Available on short notice. Salary expected, $2500 per year. H-274.

SALES ENGINEER. Graduate mechanical engineer having charge of New York territory for the past ten years for well-known company manufacturing factory equipment would like to make a change. At present employed. Highest references. H-275.

ASSISTANT TO EXECUTIVE. M.E., Cornell, age 31. Experienced as a machinist, draftsman and foreman. Desires position as assistant to an executive in a manufacturing or engineering firm where there will be an opportunity for advancement. H-276.

DESIGNING ENGINEER OR ASSISTANT TO EXECUTIVE. Mechanical engineer, university graduate, not liable for military service. Fourteen years' broad experience in the design and construction of special machinery, tools, jigs, etc., including ordnance, design of ammunition-handling devices, hydraulic machinery with automatic controlling attachments, structural-steel design and specifications. Familiar with shop methods and follow-up work. Thoroughly practical, with executive ability; not afraid of work or responsibility. Available on short notice. H-277.

RAILWAY MECHANICAL ENGINEER. Age 38. Technical education and 18 years' experience as railway machinist, draftsman, chief draftsman and mechanical engineer. Desires position with railway company, railway-equipment manufacturing company, supply house or industrial plant, with greater responsibility and opportunity. At present employed. Location immaterial. Salary $3000. H-278.

MECHANICAL ENGINEER OR SUPERINTENDENT. American, 14 years' practical and theoretical experience. Specialist in valves, fittings and engineering specialties of all descriptions; machines, tools, fixtures and equipment for same, shop maintenance; efficiency and production engineer. Successfully held positions and has references verifying above experience. H-279.

SALES ENGINEER. Age 32, technical graduate. Four years' experience selling power-plant equipment as well as in design, erection and operation. Good executive ability. H-280.

MECHANICAL ENGINEER for industrial plants. Six years' specialized work on steam and combustion equipment. Desires position as works engineer or superintendent. H-281.

TECHNICAL GRADUATE, M.E., Columbia, age 27. Three years' factory experience erecting and repairing sugar-refining machinery. One year doing master-mechanic work in an acid plant. At present a draftsman. Desires position in munition or other manufacture. H-282.

MECHANICAL ENGINEER with metallurgical training desires position as assistant metallurgist. Four years' shop experience. H-283.

INDUSTRIAL ENGINEER. Age 33, married, technical education. Two years' practical shop experience, 4 years in drawing room, 3 years designing and erecting mill buildings and machinery. At present employed as mechanical engineer with manufacturing company. Can furnish best references. H-284.

RESEARCH ENGINEER AND COMMERCIAL DESIGNER on gas and oil engines, farm tractors or marine motors. Employed in experimental engineering department of a university in Central Northwest. Desires position in commercial or educational research laboratory or large factory devoting entire time to research or research and design. Originative ability in application of scientific principles. Active member Society of Automotive Engineers. H-285.

MECHANICAL-ELECTRICAL ENGINEER. Columbia graduate, age 32, married. Desires position as works engineer. Ten years' experience in industrial-plant engineering, including the installation and operation of power-generating, transmission and receiving apparatus, and shop machinery. Also experienced in the application of electricity to shop processes, welding, electric heating, pyrometry, etc. H-286.

HEAT-TREATING AND RESEARCH ENGINEER. Graduate M.E., age 33, married. Seven years' experience in heat treatment of all kinds of steels. Shop and research experience in large munition factory. Can take full charge of all heat-treating and pyrometer testing. H-287.

MECHANICAL ENGINEER. Columbia graduate, 1912. Five years' experience in design, construction, and inspection with prominent concerns. Desires position in engineering department, or as assistant with good chance of advancement. Employed at present. Salary $1800 to $2000. H-288.

GRADUATE of university mechanical engineering course, age 26, desires position with a manufacturing plant or steel works where chances for advancement into the business end are good. H-289.

SALES PROMOTER. Successful specialty sales manager and salesman, especially good on introductory work, is open for high-grade connection. Enthusiastic, convincing talker, with initiative, stability, good appearance and judgment. Accustomed to handle large business; age 37, American born, single, technically educated, with practical experience. Has covered territory from New York to San Francisco. Will go anywhere. No objection to long trips. H-290.

EXECUTIVE OR WORKS MANAGER. Mechanical engineer with wide experience in positions as executive manager and engineer. Specialty, small arms and interchangeable parts production; last six years' work has been in that line. Position in East preferred. H-291.

EXECUTIVE position in the steel business either in the manufacturing or sales end desired by an American, technical graduate. Age 36; married. Fifteen years' experience in steel plant, general construction and varied engineering work. At present employed. Will arrange for New York interview. H-292.

MECHANICAL ENGINEER. American, 33, married. Technical education. Experienced in standardization work in manufacture, in design of heavy machinery, structural work, concrete. Engineer of construction. Especially experienced in power-plant construction and in combustion engineering. H-293.

MANUFACTURING EXECUTIVE desires to locate with progressive organization producing mechanical or electrical material. Has executive and practical experience in engineering and efficiency methods, costs, inter-department systems, tools, machinery, equipment, power, labor-saving methods, quantity production. Available after one month's notice. Location New York or vicinity. H-294.

BOILER MAN fully conversant with every detail of design and construction of steam boilers, particularly water-tube boilers, oil burners as well as automatic stokers, building, erecting, static and efficiency tests. Will be open for responsible position by August 20. Location near New York City. Highest references. H-295.

STEAM-TURBINE ENGINEER. Fifteen years' experience in the design, manufacture, testing and operation of all commercial types, especially small units, in U. S. and abroad. Desires to make a change. H-296

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and a Selected List of Engineering Articles

National Committee on Gas and Electric Service

SOME months ago the Committee of the American Gas Institute to Coöperate with the Government in regard to the Military Needs of the Nation and the Committee of the National Electric Light Association on War Conditions, at a joint conference held in New York City, decided to organize a National Committee which would secure to the United States Government the most effective coöperation in the conduct of the war from the gas and electric light and power industries. The National Committee on Gas and Electric Service was thereupon organized with a membership of representative men from these two industries and the related natural gas industry. The Committee, as constituted, has the following members of The American Society of Mechanical Engineers on its roster:

JOHN A. BRITTON, Vice-President, Pacific Gas and Electric Company, San Francisco, Cal.

ALEXANDER DOW, President, Detroit Edison Company, Detroit, Mich.

CHARLES L. EDGAR, President, Edison Electric Illuminating Company of Boston, Mass.

A. E. FORSTALL, President, American Gas Institute, New York, N. Y.

D. C. JACKSON, Professor of Electrical Engineering, Massachusetts Institute of Technology, Boston, Mass.

S. S. WYER, Consulting Engineer, Natural Gas Industry, Columbus, Ohio.

JOHN W. LIEB, Vice-President, The New York Edison Company, New York, N. Y.

The Committee is recognized by the Advisory Commission of the Council of National Defense as one of its advisory committees, and it has established an official headquarters in the Munsey Building, Washington, D. C., where it has placed itself at the service of the Government for any assistance it may be able to render in behalf of the public-utility industries it represents. It is prepared to act as a vehicle of communication between the various instrumentalities organized by the Government for the conduct of the war and the gas companies producing and distributing artificial and natural gas and the electric light and power companies furnishing electric service, in all matters relating to the national defense. It proposes to place promptly at the disposal of the Government any data or information which it may require as to the facilities in men or service which they may have available, to insure the continuous operation of their plants so as to enable the munition plants, navy yards and manufacturing establishments, through continuous and uninterrupted service, to maintain their maximum output, and it will endeavor to provide the Government with the necessary quantity of the essential by-products they can make available for the production of high explosives and of ammunition.

One of the most essential requirements in the coördination of the industrial resources of the country for the successful conduct of the war is to provide a regular and adequate supply of fuel to the important utilities engaged in enterprises through which they render service to the Government and to the public. To facilitate solving the many problems affecting the continuous supply of fuel to operate their plants, the National Coal Board has been pleased to appoint Mr. George M. Elliott, Secretary of the Committee, to membership on the Coal Committee. A questionnaire has been prepared and forwarded to every gas and electric light and power company in the country, asking them to send a statement of the various kinds and quantities of fuel each uses per annum for its various purposes, the water or rail connections over which they are received, together with a monthly statement of fuel contracted for, received and consumed. This will enable the Committee to give prompt information to the authorities of fuel shortage in any particular locality, with the transportation lines involved, loading and unloading delays, car shortages, routing and trans-shipment difficulties, etc.

Scientific Research in France

IN a paper under the title Organization of Scientific Research in France, presented by Henry Le Chatelier to the Academy of Sciences, the author bitterly complains of the slight estimation in which science is apparently held by society and government in France. He states that men of science are never consulted on measures of public interest, even those most directly connected with science, such as, for example, problems of organization of public education. He claims that science is not appreciated in France to the same extent as it is in Germany. There the captains of industry are proud of the right to prefix the title of Doctor. In France a man who would follow the same custom would make himself ridiculous. In England industrial magnates are quite flattered at being invited to preside at meetings of scientific societies. But that could not be done in France.

Curiously, even while we in America consider our state of research as quite backward, Le Chatelier, whose name, by the way, is quite well known in this country as that of the inventor of the pyrometer and other instruments and the author of many valuable papers on metallurgy, cites the United States as one of the examples of a progressive country where research is generously endowed.

In France there is one magnificent institution of research, the Pasteur Institute, of which the country is proud, but only one. As regards laboratories created specifically for industrial research, there is only the Experimental Station of the Coal Mines Committee at Lievin, maintained by the Coal Mines Company. While this laboratory is very well equipped, it does not make much of a showing as compared, for example, with the numerous laboratories of the German syndicates, metallurgical, mining, ceramic, cement industries, etc.

A field in which still more remains to be done is the creation of private-plant laboratories serving the needs of individual concerns. According to the statement of the writer, a good many industries completely neglect the use of laboratories and none knows how to fully profit by them.

When one comes to consider ways and means to remedy this deplorable condition, one finds that the main difficulty is the [illegible] of the educated classes in French society with respect to the [illegible] and usefulness of science.

Our [illegible] engineers, even those who have arrived at [illegible] in the industry, say: "Our study of science has never been of any use to us. It is nothing but good mental exercises, the same as fencing exercises are good bodily, even if one does not intend to use the art for actual purposes of fighting. Perhaps even the study of Chinese might prove of more value than that of mathematics."

Such statements are a clear proof of an incomplete scientific formation. The war, however, has thrown a vivid light on this subject and has shown in France, even if somewhat late, the exact state of affairs.

The principal error in the past has been that science was reduced to a collection of facts and laws; that is, to only the results of science, and in the presence of the immense number of problems facing the industry only a few of these results acquired with so much effort could be utilized in the course of the career of an engineer. Therein lies the explanation of the apparent uselessness of the study of science. But, side by side with the results there is the method of science, that which produced these results, and this method contrary to what is the case with the results themselves can be of daily application. It is to training in this way that the teaching of science should be exclusively devoted. It is not enough to clutter the mind with a variety of bits of knowledge; what should be done is to give it a certain formation.

This point of view being admitted, certain consequences immediately result therefrom. The basic method of physical sciences is the experimental method, and it is acquired in the laboratory and not in front of a blackboard. Therefore, the extension of laboratories, or rather their better utilization, as there are already a good many of them in universities, should apparently be the dominant problem in all reforms of our system of tuition. (*Revue de Métallurgie*, vol. 13, no. 3, May-June 1916, p. 161 and following.)

Changes in Boiler-Plate Specifications

As a result of an investigation by the Bureau of Standards of the requirements of the Steamboat Inspection Service for steel boiler plate, the interesting fact has been developed that the specifications heretofore in force have been unnecessarily severe and may be safely relaxed so as to increase the output without in any way lessening the safety of this material. Following the Bureau's report the executive committee of the Board of Supervising Inspectors of the Steamboat Inspection Service, at a meeting recently held here, has adopted a series of amendments in the general rules and regulations.

One of the most important changes recommended by the Bureau of Standards is the raising of the sulphur limit in open-hearth steel from 0.04 to 0.05 per cent. No change is made in the phosphorus, the amended rule reading as follows:

> Open-hearth steel shall contain not more than 0.04 per cent of phosphorus nor more than 0.05 per cent of sulphur.

The Bureau also recommended the adoption of a new rule relating to tensile-test specimens and quench-bend specimens which has been adopted, as follows:

> Two tension tests and one quench-bend test shall be made from each plate as first rolled from the billet, slab, or ingot, the tensile-test specimens to be taken from the diagonal corners of the plate, and the quench-bend specimen to be taken from that part of the plate which represents the top of the billet, slab, or ingot.
>
> The quench-bend specimen shall withstand, without fracture, being bent over until the ends are parallel and the inner radius equal to one and one-half times the thickness of the test specimen.

Section 18, Rule II, all classes, of the general rules and regulations, has been stricken out and a modified rule for determining the working pressure on flat surfaces of boilers has been adopted.

All the amendments agreed upon by the Board of Supervising Inspectors will be embodied in detail in a circular letter entitled "Sixth Supplement to General Rules and Regulations," which will be issued within a few days by the Steamboat Inspection Service to boiler manufacturers, manufacturers of boiler plate, steamboat companies and others. The circular may be obtained on application to United States local inspectors of the Steamboat Inspection Service. (*The Iron Age*, vol. 100, no. 2, July 12, 1917, p. 79)

New Navy Specifications for Steel Castings

New specifications governing the manufacture of steel castings have recently been issued by the United States Navy Department. They are dated May 1, 1917, and are designated as 49 Sld, superseding those issued June 1, 1916. The chemical and physical properties demanded by those specifications are as follows:

Grade	Percentage Chemical Composition (not over)		Physical Requirements				
	P	S	Minimum Tensile Strength, Lb. per Sq. In.	Minimum Yield Point, Lb. per Sq. In.	Minimum Elongation, Per Cent in 2 in.	Minimum Reduction of Area, Per Cent	Bending Test[2] (not less than)
F[1]	0.05	0.05	85,000	53,000	22	35	120 deg.
A	0.05	0.05	80,000	45 per cent of tensile strength obtained	17	20	90 deg.
D	0.05	0.05	70,000		22	30	120 deg.
B	0.06	0.05	60,000		22	30	120 deg.
C	0.06	0.07	....	....	..	..	......

[1] Grade F castings may contain nickel or other alloying metals.
[2] Cold bend about an inner diameter of 1 in.

It will be seen that the sulphur requirements are not over 0.05 per cent in all grades of castings except Grade C, which is not tested in any way.

Grade A is intended for all important parts subject to crushing stresses or surface wear only, such as hawse pipes, chain pipes, turret roller paths, engine guides, slippers, etc.

Grade B is intended for parts subject to tensile or vibratory stresses, such as stems, stern posts, stern tubes, rudder frames, struts, engine bedplates, cylinders, gun-mount stands, carriages, slides, and other parts subject to the shock of recoil.

Grade C is intended for gun mounts, such as brackets, levers, wheels, etc., not subject to shock of recoil, and for commercial fittings where structural strength and separation of watertight compartments are not involved, such as pipe flanges (other than bulkhead and deck), cagemast fittings, stowage lugs and clips, hinges for doors and hatches where watertightness is not involved, etc.

Grade D is intended for the same general purpose as Grade B, but where greater strength is required with equal ductility.

Grade F is intended for castings for gun yokes, gun-mount stands, carriage slides, deck lugs, etc., of large size.

The latest specifications of the Navy for structural steelwork, dated Feb. 1, 1917, and designated as 48 Slc, demand not over 0.05 per cent sulphur and phosphorus in all steel castings used in yards and docks and similar work and limit the sulphur to 0.045 per cent for rivet steel for bridges and buildings.

It is known that in many cases it has been difficult to meet a sulphur specification of not over 0.05 per cent in recent months, even in acid open-hearth work. The intensive stress for output under which blast furnaces and coke plants have had to operate has tended to increase rather than diminish the quantity of sulphur in these raw materials, thereby making it still more difficult for steel makers to meet specifications. (*The Iron Age*, vol. 100, no. 2, July 12, 1917.)

News of Other Societies

Annual Meeting of the S. P. E. E.

THE twenty-fifth annual meeting of the Society for the Promotion of Engineering Education was held in Washington, D. C., July 6 and 7, in coöperation with the Committee on Engineering and Education of the Advisory Commission of the Council of National Defense. The main topic of the meeting was the relation between the engineering schools and the national Government during the present emergency. An ambitious program was prepared which featured a number of addresses by government officials, by engineers rendering service at Washington on various public and semi-public committees at this time, and by representatives of foreign governments also on business in the capital. Considering the important calls upon the time of these men, the program was very satisfactorily carried out and there were but one or two disappointments.

The trend of opinion at the meeting was that students in engineering courses should be urged to continue their studies to completion rather than enlist in the national service, since by so doing they would ultimately become of much greater use to their country as trained specialists. On the other hand, the schools themselves should possibly devise means of speeding up their work so that men could complete their courses in less time and in consequence more men would be available. Opinions were also expressed that the engineering schools should introduce military instruction into their curricula.

President G. R. Chatburn occupied the chair during the meeting, and at the opening session greetings from Canada were extended by Dr. A. S. Mackenzie, president of Dalhousie University, who recited the mistakes of Canada at the outset of the war, especially in regard to the men in her engineering schools, and hoped this country would profit by the lesson Canada had learned.

Dr. S. P. Capen, specialist in higher education of the U. S. Bureau of Education, discussed the resolutions passed at a meeting of college presidents called by the Advisory Commission of the Council of National Defense. He considered it especially desirable that a comprehensive policy of coöperation between the colleges and the Government be established and maintained.

Dr. Hollis Godfrey, member of the Advisory Commission of the Council of National Defense, delivered an interesting address upon The Consulting Engineer in Public and Private Service, in which he reviewed the construction of the Council of National Defense, a body created to "coördinate the industries and resources for the national security and welfare." He spoke of the consulting engineer in his relation to the Government and of his place in making effective governmental organization and machinery in time of war.

The Hon. Newton D. Baker, Secretary of War, pointed out the duty of engineering schools in war. He said in part:

> The progress in the art of war is from day to day, not from year to year. There is almost lightninglike rapidity in ingenuity being fed to the troops at the front. There must be the same sort of response by the engineering scientists of this country. All must learn by constant reading and study, by evolving and bringing to as near completed form as may be advantageous to our efficiency and safety.
>
> In addition to that, the larger subject is the relation of engineering education and technical education to the prospective needs of the country. We are in need of fresh accessions of trained young men from the technical schools of the country. Our Coast Artillery and our engineer departments are in constant need of large accessions and they can get them at their very best from the schools. It therefore becomes the necessary thing that the great engineering schools of the country should in large part contribute to the actual organization of the Army in peace time a substantial part if not the major part of peace-time preparation for our defense should aggression force us into defensive action.
>
> I hope, therefore, that it will be assumed that one of the functions of the colleges and technical schools ought to be so to modify their curricula that the young men who have special aptitude for the scientific things which are useful in military science will have an opportunity to develop their aptitude and bring their talent to the aid of their country either for peace-time preparation or in an emergency such as faces the country now.
>
> So that my suggestion is that all of the engineering and scientific talent of the country—and the utmost pressure should be devoted—study the solution of the scientific problems presented by the war. You ought to expedite the training of young men for immediate use by the Government in this great emergency, and you ought to look forward for the future to a large contribution of your great engineer schools and colleges and collaborate the training so that it will be very easy for the young men to render a maximum assistance to the Government if the emergency comes.
>
> Nobody knows what the world is going to be like when this war is over. No imagination is able to picture the sort of civilization the world will have after this conflict is over. Nobody knows how long this war is going to last. But we do know that when this war is over the rehabilitation of a stricken if not paralyzed civilization is going to be a long-drawn-out and uphill task, and there will be need on every hand for trained minds, for trained and schooled men. That day of the engineer will be indeed the big day. Men should then be present in very great numbers to help bring about the rehabilitation of industries, the reconstruction upon an earth which has been swept by an all-consuming conflagration.
>
> And so I think you ought to have as an especial object the urgent invitation to young men of America to come into your technical schools and devote themselves to engineering branches of education: so that when this war is over the struggle will not have been in vain: so that young men can quickly and efficiently play a part in that reconstruction.

Brig. Gen. W. M. Black, Chief of Engineers, U. S. A., emphasized that for the good of the country the four-years' course in the engineering schools should be kept up and that men should not be graduated "half educated." He also thought we had enough men in the country without taking trained specialists "to shoulder a musket." Classes should keep right on with their work as in normal times, but of course if any young men particularly wanted to go to war, let them go.

Dr. Philander P. Claxton, U. S. Commissioner of Education, expressed his opinion that every man in the technical schools should remain there until he had completed his course, unless he left to do some work that could not be well done by some other person.

Commander Cluverius, U. S. N., described the methods adopted at Annapolis to speed up the courses and graduate men. He suggested that the schools along the Atlantic coast giving courses in marine engineering could do very effective

[illegible] the proper operation of steam engines and boilers.

Among the speakers were also Dr. W. P. McClellan, director of the Intercollegiate Intelligence Bureau, who described the work of the Bureau in getting graduates to fill positions in the civil service and in the enlisted service; Dr. S. W. Stratton, director of the U. S. Bureau of Standards, who described in an interesting manner the diversity of problems coming before the bureau; Civil Service Commissioner Galloway, who conveyed an idea of how the Commission is meeting the great demands now being made upon it by government departments for men; Mr. Frank B. Gilbreth; Prof. W. F. Durand, member of the National Research Council, who described the work of the committee on engineering of the Council; Prof. A. L. Williston; Dr. George Smith, of the U. S. Geological Survey, who emphasized the Government's great need of topographical engineers; Prof. H. Wade Hibbard; Dr. F. H. Newell, who pointed out the great shortage of engineers in state and city service; Prof. I. W. Lichfield; Prof. W. M. Thornton; Prof. W. G. Raymond; Prof. F. P. McKibben and Prof. F. H. Constant; Dr. J. A. L. Waddell.

On the second day a number of committees of the society, including those on engineering, education, physics, chemistry, English, mechanics and hydraulics and economics, reported the progress of their work.

At the close of the meeting Dean Milo S. Ketchum was elected president of the society for the ensuing year, and the retiring president, Dr. Chatburn, delivered his presidential address, entitled Our Patriotic Duty. Dr. Chatburn reiterated the necessity for speeding up the college courses, making any changes necessary in the curricula and then, if the war proves short, changing back again.

Society of Automotive Engineers

The S.A.E. held a two days' meeting on June 25-26 in Washington, momentous in the history of the society both because of the important problems considered and because of the very hearty and active participation of the Government. The idea of holding the meeting at the nation's capital was shown to be distinctly proper. As *The Automobile* (June 28, 1917, to which credit should be given for an excellent account of this meeting) states, there was hardly a report of the Standards Committee and not a single paper that was not strongly touched with the influence of the war problems on the nation.

The meeting opened on June 25 with the Standards Committee section at the Bureau of Standards Building, and was attended by a large number of members of the society who were not members of the Standards Committee. This had the good result of familiarizing the membership with the work done by its Standard's Committee before the resolutions were brought up for action by the general society. Hence, no delay was experienced and the entire conduct of the meeting was accelerated.

A number of new standards have been added covering matters aeronautic, research, parts, engines and electrical equipment.

The professional session held during the afternoon of the second day had six papers on its program, of which four were actually ready. Henry R. Sutphen, of the Elco Boat Company, presented a paper dealing with the standardized construction of high-speed motor boats used as submarine chasers, a subject on which he was particularly qualified to speak, as the Elco Company, under his direction, performed the remarkable feat of delivering to the British government in record time 550 80-ft. submarine chasers.

Wing Commander I. W. Seddon, of the British Commission, who has had actual war experience with the Royal Flying Corps, spoke of the design and construction of aircraft in war time and gave his views on the way in which America could aid in establishing the supremacy of the air.

Lieut. Amaury de la Grange, of the French Commission, who also took part in military flying on the other side, spoke of the classification and uses of battle planes and of what America can do in this connection.

H. L. Horning (Mem.Am.Soc.M.E.) presented a paper on Tractors and the Food Problem, discussing not only the immediate demands created by the war, but also those which may be expected to come from the pressure of the coming increase in the population of the world.

An interesting and pleasant feature of the meeting was that constituted by the participation of the highest Government officials in the work of the society. Thus, at the dinner of the society on June 26 in the grand ballroom of the New Willard Hotel, as chief speaker of the evening appeared Secretary of War Baker. The keynote of his speech was that the United States was now engaged in war and a twentieth-century war it was. When the history of this war is finally written it will be shown that we won because we were able to contrive more ingenious engines than our adversary. To reduce the percentage of our losses, we shall have to make use to the fullest possible extent of all the appliances which modern science affords. Aeroplanes would be a great aid in this connection. We must make better and more aeroplanes, so that we can see where our adversaries cannot. Engineers building aeroplanes should realize that they are as truly winning battles as though they were engaged at the front.

Edward A. Deeds (Mem.Am.Soc.M.E.), Chairman of the Aeroplane Construction Board, gave some information regarding the activities of the Aircraft Production Board which was organized on May 6 last and is now under the chairmanship of Howard E. Coffin (Mem.Am.Soc.M.E.).

American Society for Testing Materials

The annual meeting of the American Society for Testing Materials was held at the Hotel Traymore, Atlantic City, N. J., June 26-29, 1917. Among other activities of the meeting the following papers were presented:

The Committee on Steel, C. D. Young (Mem.Am.Soc.M.E.), Pennsylvania Railroad, Chairman, recommended a number of revisions in both standard specifications and tentative standard specifications and proposed a new tentative standard specification for carbon tool steel.

These specifications cover tool steel in ten classes and three grades determined by the chemical composition specified in a table. In this specification maximum manganese is given for the three grades, A, B and C, respectively, as 0.40, 0.45 and 0.60; phosphorus as 0.02, 0.025 and 0.035; sulphur 0.02, 0.035 and 0.04; and silicon 0.35, 0.35 and 0.25.

In the specification for steel tie plates are described two types of specimen which may be used. The 2-in. specimen of circular cross-section shall have filleted shoulders or threaded ends to fit into the holders of the testing machine in such a way that the line of action of the force exerted by the testing machine shall coincide with the axis of the specimen. Tension-test specimens may also be rectangular in section, in which case there shall be not less than $1\frac{1}{2}$ in. in width between the plane sides, and the test piece shall have two parallel faces

as rolled. When the tie plates are of such a design that the rectangular specimens cannot be obtained with out projecting ribs, these shall be planed off before the tests are made.

L. N. Edwards presented a paper entitled The Effects of Grading of Sand and Consistency of Mix upon the Strength of Plain and Reinforced Concrete. This paper describes the methods used and gives the results obtained from tests made upon (1) cylinders in which 12 sands of predetermined gradings were used as sand aggregates; (2) cylinders and reinforced-concrete beams, in the preparation of which five consistencies of mix were used; and (3) cylinders for which the time of mixing was varied from $\frac{1}{4}$ to 2 min.

The writer came to the following conclusions:

1 The commonly practiced "visual examination" test of sand aggregate for concrete is generally unreliable, since it gives at best only a superficial knowledge of the cleanliness of a given sand. Its adaptation to the determination of grading could be of value to the observer only after long experience in the granulometric analysis of sands.

2 The generally accepted practice of proportioning a concrete mix by volume, as, for example, 1 part cement, 2 parts sand and 4 parts broken stone, is impracticable and unscientific, since it does not take into account the adaptability of the grading of a given sand to the production of a dense, strong and reliable concrete. Proportioning by volume, as commonly used, gives no guarantee of the production of a concrete having a desired strength, hardness, or other physical properties.

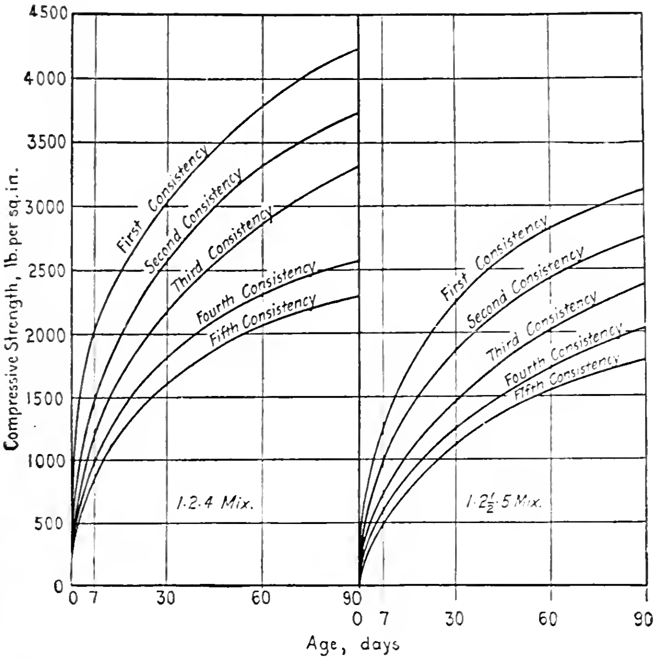

FIG. 1 COMPRESSIVE STRENGTHS OF TEST CYLINDERS OF DIFFERENT CONSISTENCIES

3 The strength, toughness and durability of concrete to be secured from the use of a given sand can be determined only by actual test of that sand in a properly prepared concrete.

4 In field operations incident to spading, slicing, or otherwise compacting the concrete, the movement of the water content of the mass is intensified whenever the sand aggregate contains sufficient fine material to hold the cement in suspension by the formation of an adequate amount of sandy paste. The free movement of the water tends to produce an improper distribution of the cement.

Fig. 1 shows the compressive strengths obtained from the tests of cylinders, in which the consistency of the mix was varied from a sticky, semi-plastic to a very wet condition. The sand and stone were of limestone origin.

Several conclusions may be drawn from these results. The use of a quantity of water sufficient to produce a concrete the mortar component of which is of a saturated, sticky, semi-plastic consistency, is for most practical purposes required in order to facilitate economical and efficient placing. The quantity of water is ample for the development of the proper functions of the cement. An increase in the quantity of water used results in a proportionate decrease in the strength of the concrete. This decrease is in no sense a function of the proportions of the mix.

The results of the test on the influence of time of mixing

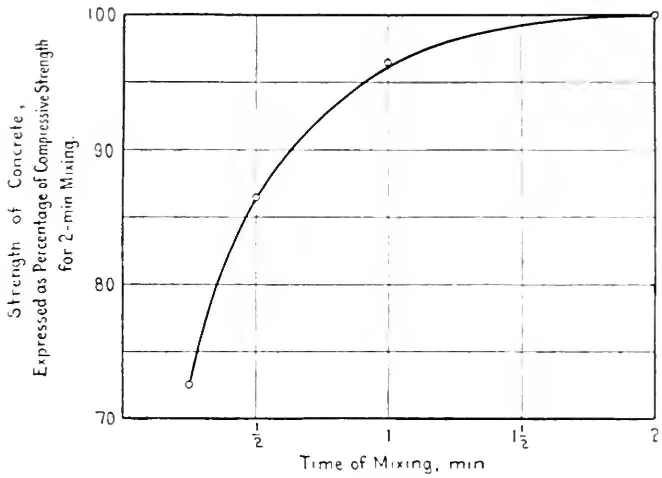

FIG. 2 RELATION OF TIME OF MIXING TO COMPRESSIVE STRENGTHS OF CONCRETE

are shown in Fig. 2. The abrupt change in the direction of the curve at the location indicating the 1- and 2-min. period of mixing, together with the rapid increase of strength shown for mixing periods of less than 1-min. duration, show exclusively the advantage gained by continuing the mixing operation for a period of from 1 to 2 min. after all the materials have been placed in the mixer.

H. A Gardner presented a paper on Metal Primer Tests reporting the continuation of his researches on painting materials (previously announced at other meetings of the same society).

In previous tests the writer observed that red lead which has been highly oxidized during production and which is, therefore, practically a neutral pigment, is not as well suited for application to metal as red lead which is highly basic in nature and which contains a considerable percentage of litharge. In the present tests it has been demonstrated that incompletely oxidized or highly basic red leads have a superior value. This was shown by an inspection of the paints at the end of three years' exposure.

The tests have further demonstrated that two coats of the neutral iron-oxide paint (chromated or containing zinc chromate or zinc oxide) are superior to two coats of the neutral red-lead paint. It has also been demonstrated that excellent results can be obtained with one coat of a highly basic red lead. Further a comparative durability of one- and two-coat work on an iron-oxide, zinc-oxide paint was demonstrated. The results obtained would indicate that all metal should preferably be given two coats of paint when erected.

The same series of tests covered problems of storage of red

lead in package. Some of the paint used in this test had been stored [illegible] three years in half gallon cans. When the cans were opened some of the clear oil was removed from each package and ashed to determine the amount of pigment that had gone into the solution.

The results indicate that red leads high in lead tetroxide are quite as soluble in linseed oil as red leads high in lead monoxide. The condition of the paints, observed at the time of opening, would seem to indicate that the softness of red-lead paints after aging is due not solely to the amount of litharge contained therein, but also to the settling properties of the red lead. In other words, red leads of high weight per volume will settle down to the bottom of the cans and become hard; whereas, red leads of low specific gravity are more likely to be maintained in a bulky form.

The results obtained in the storage tests indicate that some chemical action takes place other than that which can be accounted for by the formation of lead linoleate. The writer is of the opinion that the chemical reactions which are partly responsible for the hardening of red-lead paints cause the formation of lead glycerinate, a substance that is recognized as one of the hardest and one of the most durable cementing materials. (Abstracted through the *Railway Age Gazette,* vol. 63, no. 1, July 6, 1917 pp. 13-16, 4 figs., *ge*)

Junior Institution of Engineers

IN THE course of a short paper on Gas Turbines, recently read before the Junior Institution of Engineers, Mr. S. E. Hutson stated that the great hindrance in the way of the development of the gas turbine as a commercial unit was the, at present, insurmountable difficulty of finding a metal which would withstand the extremely high temperature of the gases. He referred to the general lines along which most gas-turbine designers had proceeded, and showed that practically all the experimental machines which had been built were based upon one of three principles. The first involved the use of a combustion chamber lined with refractory material into which some form of fuel was forced, together with such an amount of compressed air as was necessary for combustion. The gases were ignited in this chamber, and were then directed on to the buckets of an impulse wheel after passing through the diverging nozzles. The air and fuel were driven into the combustion chamber by means of pumps or compressors, which took power from the turbine. The second type of turbine was based on much the same principle as the first, but was fitted with a water jacket which surrounded the combustion chamber. The third principle, which the author considered the most feasible and upon which he had himself been working, was described as the regenerative principle. In this case a charge was forced into the combustion chamber, surrounded by the water jacket, and, after combustion, was brought down to a temperature more suitable to the turbine blading, on to which it was passed through nozzles. The reduction of temperature in the combustion chamber was brought about by steam generated in a special type of boiler placed in the path of the gases as they exhausted from the turbine. After briefly describing several of the experimental machines which had been built by British and continental engineers, Mr. Hutson described the designs of a turbine for which he was largely responsible. This design was based upon the regenerative principle, and in many points showed considerable ingenuity; but Mr. Hutson had found himself up against most of the difficulties which had confronted other experimentalists, and, as he admitted, his efforts had been attended with as little success as theirs. In the first place, he had been unable to obtain a suitable material to withstand the high temperature of the gases. He had, moreover, found that in nearly all the experimental turbines which had been built, the fuel and air compressors had consumed a very large percentage of the output of the machines, but on his machine Mr. Hutson had naturally had to resort to the use of a feed pump to get the water into his boiler, which was an additional drain upon the power developed by the turbine. (*The Mechanical Engineer,* vol. 39, no. 1013, pp. 442)

Notes from the Engineering Colleges

Equipment of Laboratories—Investigations in Progress—Changes in Curricula

BELOW is a continuation of the review of professional work being undertaken at the engineering colleges. The articles contain information regarding (1) characteristics of laboratory equipment, (2) tests or researches under way or in prospect, (3) important changes in curricula.

The articles will be concluded next month.

UNIVERSITY OF CINCINNATI

Research Work: The principal investigational work carried on in the Department of Mechanical Engineering was a study of times of explosions of mixtures of natural gas and air. This work was undertaken over a year ago, and results which were thought to be reasonably accurate were secured. The experiments made at that time suggested certain refinements in apparatus, which have been followed during the past year.

The apparatus is an interesting device for obtaining a graphical record of the explosion of a gas in a closed vessel. The principal feature is the use of an oscillograph. The pressure due to the explosion of the gas is made to act directly on a steel diaphragm in the wall of a cylinder. The deflection of this diaphragm displaces a small amount of mercury from a well, causing it to move up a glass tube of small bore. Within the glass tube is a small carbon filament carrying an electric current. The movement of the mercury column along the carbon filament varies the resistance and hence the amount of current flowing in the circuit. Since the oscillograph registers instantly any variation in the current, the building up of the pressure in the cylinder is accurately recorded.

This type of apparatus can be adapted for use on a gas-engine cylinder, since it will follow very rapid fluctuations in pressure and can therefore be used to determine the proper mixture. It was used in the University laboratory to study the time of explosion and the pressure produced by various mixtures of air and natural gas. The advantages obtained by its use were that no carbon deposits could interfere with the moving parts, and that there was practically no inertia effect. The time of the explosion was obtained by sending a 60-cycle alternating current through the oscillograph at the time of the explosion. Then the distance from peak to peak of the alternating-current wave represented to scale 1-60 sec., and the time between various points on the explosion curve could be read directly in sixtieths of a second.

The apparatus consists of an explosion cylinder, gas meter, vacuum pump, and oscillograph, and is shown set up in Fig. 1. A number of tests were made with varying amounts of gas, and different ratios of gas and air. No difficulty was found in adjusting the apparatus to record both the extremely rapid explosions of rich mixtures and the much slower explosions of lean mixtures. Table 1 gives typical results.

In typical curves obtained it is noticed that after the spark is passed the pressure increases very slowly for a time, then there is a rapid increase to maximum pressure.

Another piece of work done was an analysis of a Stuebing lift truck. A series of graphs was obtained of the force required to drag the truck over concrete, wood-block, and steel-plate floor surfaces, with different loads and using plain and roller bearings. The graphs were continuous, showing the starting, maintaining, and stopping forces. Static tests were made to ascertain the strength of various parts of the machine under load. One of the interesting features of the experiments was that the wheels of the truck were caused to revolve while the truck was under load for an equivalent of eighty miles of travel. Chemical analyses of these steels were obtained and microphotographs of a section of each shaft after use in the roller bearings, to show the change in structure of the material. One such microphotograph is shown in the accompanying Fig. 2.

TABLE 1 TYPICAL EXPLOSION DATA

	No. 1	No. 2
Ratio of mixture	14.6 to 1	10.8 to 1
Volume of natural gas, cu. ft.	0.040	0.080
Initial pressure, lb. per sq. in.	40.0	60.0
Maximum pressure, lb. per sq. in.	190.0	415.0
Time between spark and rapid increase in pressure, sec	0.10	0.05
Time between rapid increase in pressure and max. pressure, sec.	0.23	0.11
Time between spark and max. pressure, sec.	0.23	0.157

Several interesting tests were begun upon machine tools. One was of a large new-type milling machine. The principal deflections of the main frame members of a column-and-knee-type milling machine were obtained by means of static loading. This load was first applied in a horizontal direction then 45 deg. with the table. The comparative deflections due to both twisting and bending of the main units were obtained. The power consumed at the cutter in removing cast iron was obtained. The meters, motor and machine were calibrated.

Other work consisted of tests of a 6-ft. plain radial drill when drilling holes of various diameters in cast iron and machinery steels. An apparatus was designed for obtaining the power required to feed a drill and to turn the drill. The apparatus is now complete, but the tests have not yet been made. It is expected that this will be done this summer.

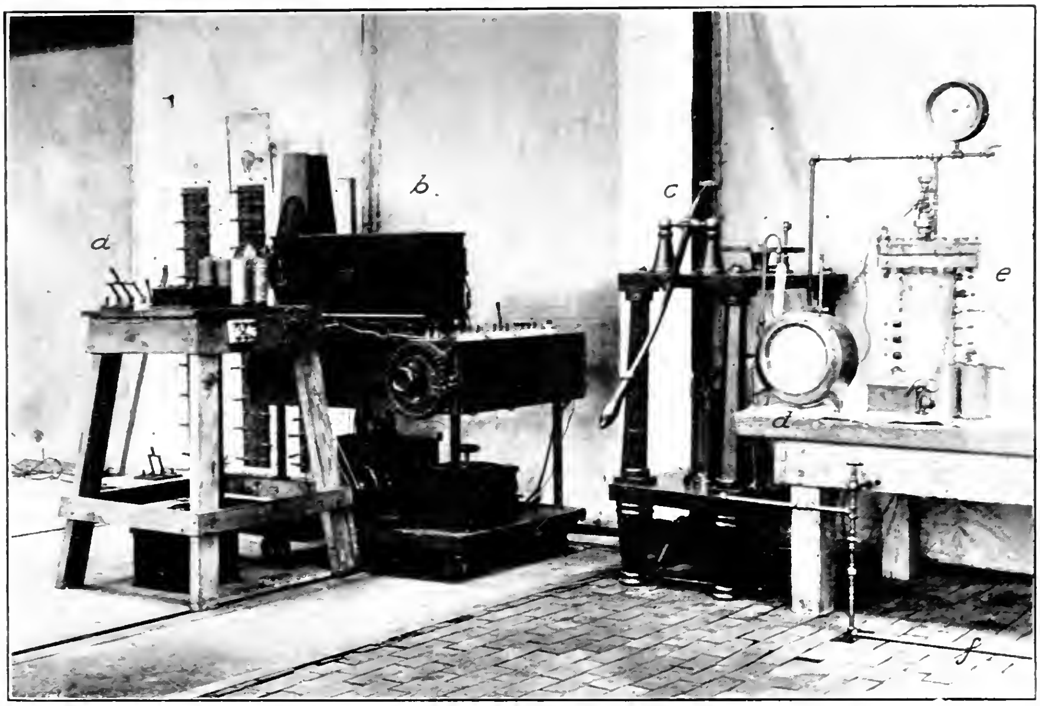

FIG. 1 APPARATUS FOR STUDYING TIMES OF EXPLOSIONS OF MIXTURES OF NATURAL GAS AND AIR
a, Operating Bench; *b*, Oscillograph; *c*, Vacuum Pump; *d*, Gas Meter; *e*, Explosion Cylinder; *f*, Compressed Air.

Equipment: A new electric dynamometer has been purchased for the measurement of power of internal-combustion engines of high speed, which has a capacity of 100 hp. and 3500 rev. per min. In the design of this dynamometer careful study was made of existing dynamometers at the Automobile Club of America and elsewhere, and it is believed that very delicate tests will be possible on this machine.

FIG. 2 MICROPHOTOGRAPH OF SECTION OF A SHAFT AFTER USE IN ROLLER BEARINGS (0.20 CARBON, 0.39 MANGANESE)

University of Michigan

Equipment: Special equipment for the testing of heating and ventilating apparatus; radiator-testing apparatus and other special heat-testing devices, small refrigerating plant for special research work, besides standard instructional apparatus.

The new university power plant contains a 500-kw. cross-compound, non-condensing steam engine; a new 275-kw. turbine of the impulse type is about to be installed.

Experimental Work: Tests on steam radiators to determine coefficients under different circumstances, such as location, and the characteristics of different types of radiators; also to determine the effect of enclosing a radiator in a nook with a grating in front; determination of the rate of heat transfer through an iron coil and through a brass coil located in a tank of water; investigations to determine coefficients for sharp-edged orifices in connection with the measurement of steam flow; investigation of the coefficient of friction of steam flowing in pipes at different pressures and various velocities; investigation of the coefficient of heat transfer through walls of various building materials, notably hollow building tile. Also tests on screw threads, more particularly to determine the size of tapping drill to be used in tapping out nuts up to, say, 1-in. size; and whether threads in the nuts shallower than the full-depth thread will not be just as strong as full-depth threads; what depth will make a combination as strong as the screw at the root of the thread; and stresses on taps when tapping the nuts at different speeds.

Virginia Polytechnic Institute

Equipment: The engineering laboratories are designed more on pedagogical lines than for research, and for practical utility rather than for scientific research work. There are chemical, metallurgical, physical, and agricultural laboratories.

Metallurgical Laboratory: Volume changes during the hardening and setting of silver, tin and other amalgams; possible connection between the microstructure, Brinell hardness, and the durability of valve and piston packing rings for locomotives.

Graphics Laboratory: Investigations in pure mechanism and special problems in machine design: classification of higher plane linkages, non-circular rolling wheels, parallel motions of straight-line-describing linkage; design of a dynamic balancing machine to weigh quickly and accurately the unbalanced forces of rotating masses.

Pure Mathematics: Mathematical investigation has been completed on the subject of a new transition curve.

Mining Engineering: Determination of the best methods of treating complex ore in Spottsylvania County; examination of natural deposits of ores and minerals.

Experimental Engineering: Investigation of the local power plant for a determination of the cost of heat and power per unit; test of bearing metals and dental alloys, with specially designed impact machine; freezing and oil-penetration tests of cement and concrete; test of brick of the state for the American Society of Testing Materials.

Quite radical changes in the courses of instruction are now being prepared. On account of the improved condition of the primary schools of the state, the degree courses in engineering will be reduced from five years to four years. As the entrance requirements were put on a fourteen-unit basis some years ago, this change can be made at this time.

This Month's Abstracts

THE reference, taken from a paper read before the Aeronautical Society of Great Britain, to a 475-hp. 18-cylinder engine is a good showing of what has been done abroad in the last two years in the way of developing big power plants for aircraft.

A table is reprinted giving standard dimensions of copper tubes for aircraft as adopted by the British Air Board.

In the section Engineering Materials will be found an abstract of an investigation, published by the Bureau of Standards, on the properties of component parts of portland cement. Taken in conjunction with previous data, it forms a valuable contribution to our knowledge of this important material of construction.

The data on iron-aluminum alloys melted in vacuo, taken from the *University of Illinois Bulletin,* are of particular interest as an example of an originally purely laboratory investigation rapidly becoming industrially important—first in the field of electrical engineering and now mechanical.

Attention is called to an abstract of a paper in a German periodical on the influence of radiation on fire temperature.

From the *Journal of the Society of Mechanical Engineers of Japan* are abstracted data on the thermal relations of casting and molding sand, throwing an interesting light on the processes of solidification of metal.

In the section Lubrication will be found data on a series of tests on lubricating oils, interesting both because of the results and because of the novel method adopted by the authors. Particular attention is paid to the determination of the durability of oils.

Those engaged in the design of screw pumps will be interested in the abstract of an investigation on this type of machinery taken from a German periodical. Unfortunately, the original of the article is not now available in this country.

In the section Railroad Engineering there are abstracts of several articles on locomotive engineering. Particular attention is drawn here to the description of the Pennsylvania Decapod locomotive, which embodies some quite novel features for this type of construction.

In the same section will be found an abstract of a paper reporting some tests on corrugated culvert pipe under a sand bed, the significant feature of which is that, among other things, it appears that a sand load over a culvert pipe behaves essentially in the same manner as a grain load in an elevator.

An extensive abstract is made of a paper in the *Proceedings of the German Society of Engineers* on the construction and operation of boilers for intensive service.

The absolute value of entropy and energy is discussed in an interesting manner in a paper presented before the French Academy of Sciences, and from the *Proceedings of the Royal Academy* (Great Britain) is taken an abstract of a paper on the determination of the heat of vaporization of water at 100 deg. cent, and one atmosphere of pressure in terms of the mean calorie.

The Automobile Committee of the Council of National Defense has inaugurated a comprehensive industrial inventory of the automobile industries, including automobile, airplane and watercraft factories, to make available to the Government all possible information regarding their manufacturing facilities and possibilities of expansion for Government work. The inventory is being taken by the industrial inventory section of the Council of National Defense.

REVIEW OF ENGINEERING PERIODICALS

Aeronautics

Standardization of Copper Tubes for Aircraft

Difficulties having been experienced by aircraft contractors in obtaining supplies of copper tubing, the causes were investigated, and they were found to be (1) the great variety of sizes called for and (2) the fact that tube makers received orders very irregularly and for small quantities.

Arising out of the investigation, the specification committee of the Air Board has decided that in future copper tube for aircraft contracts will be specified in terms of external diameter and legal standard wire gage. As far as possible tubes of 20 gage (0.036 in.) will be used to the exclusion of all other thicknesses. Where for special considerations it is desirable to use other thicknesses, the choice will, as far as possible, be restricted to gages 16, 18 and 22. The last-named is difficult to manufacture, and will be avoided as far as possible. A new Air Board specification for copper tube will shortly be issued, and will have as an appendix the following list of sizes and gages which the Air Board regard as standard:

20 Gage: $\frac{3}{16}$ in., $\frac{1}{4}$ in., $\frac{5}{16}$ in., $\frac{3}{8}$ in., $\frac{7}{16}$ in., $\frac{1}{2}$ in., $\frac{5}{8}$ in., $\frac{3}{4}$ in., $\frac{7}{8}$ in., 1 in., $1\frac{1}{8}$ in., $1\frac{1}{4}$ in., $1\frac{3}{8}$ in., $1\frac{1}{2}$ in., $1\frac{5}{8}$ in., $1\frac{3}{4}$ in., 2 in.

18 Gage: 1 in., $1\frac{1}{4}$ in., $1\frac{1}{2}$ in., $1\frac{3}{4}$ in., 2 in.

16 Gage: $\frac{1}{2}$ in., $\frac{5}{8}$ in., $\frac{3}{4}$ in., $\frac{7}{8}$ in., 1 in., $1\frac{1}{4}$ in., $1\frac{1}{2}$ in., $1\frac{3}{4}$ in., 2 in., $2\frac{1}{2}$ in.

22 Gage: 1 in., $1\frac{1}{8}$ in., $1\frac{1}{4}$ in., $1\frac{3}{8}$ in., $1\frac{1}{2}$ in., $1\frac{3}{4}$ in., 2 in. (*Engineering*, vol. 103, no. 2685, June 15, 1917, p. 577)

Sunbeam-Coatalen Aircraft Engines

Description of several types of these engines used in the British Army.

A feature common to all of these engines is that the crankcase and nose piece are cast in one, an arrangement which has the advantage of lightness and rigidity, as well as accessibility. Flywheels are absent.

Overhead valves are used exclusively, with two inlet and two exhaust valves per cylinder.

In the big 18-cylinder engine of 475 b.hp. there are no fewer than six magnetos, each one being enclosed. Two sparks are furnished to each cylinder from two independent magnetos. There are also six carburetors. Shortness of crankshaft and absence of vibration are achieved by the linking of the connecting rods, three cylinders working on one crankpin, the outer rods being linked to the central master one. In consequence of this arrangement, the piston travel in the case of the central row of cylinders is 160 mm., while the stroke of the pistons of the cylinders set on either side is in each case 168 mm.

In the 12-cylinder 350-b.hp. aircraft engine a duplicate ignition scheme is also employed. But this engine is characterized by the passage formed through the center of each induction pipe for the spark plug in the center of the cylinder of each block of three. (Lecture before the Aeronautical Society of Great Britain, abstracted through the *Auto*, vol. 22, no. 23/857, June 8, 1917, pp. 405-406, 4 figs., *d*)

Engineering Materials

Properties of Calcium Silicate and Calcium Aluminate Occurring in Normal Portland Cement, P. H. Bates and A. A. Klein

It has been shown previously, e.g., by Rankin (cp. abstract in The Journal, July, 1916, p. 591), that commercial portland cement is made up essentially of three constituents, viz., tricalcic silicate, dicalcic silicate and tricalcic aluminate. The present investigation has for its purpose the determination of the physical properties of these compounds, alone and mixed in various proportions.

The writers come to the following main conclusions:

1 At early periods the constituents of portland cement of normal composition and manufacture, in the order of their strength-conferring properties, are tricalcium silicate, tricalcium aluminate, and dicalcium silicate.

2 At periods beyond 28 days, the dicalcium silicate gains sufficient strength to place it almost on an equality with the tricalcium silicate.

3 Tricalcium aluminate containing 10 per cent plaster gains practically no strength after the first period at which it was tested: that is, 24 hours.

4 Tricalcium silicate of the purity used in this investigation (90 per cent $3CaO.SiO_2$ in one case and 95 per cent in the other) has all the important properties of portland cement, especially those of the "rate of setting" and strength developed.

5 Dicalcium silicate, such as used in this investigation, sets too slowly and attains strength too slowly to be of any commercial value when used alone.

6 Tricalcium aluminate alone, as used in this investigation, sets too rapidly and attains too little strength to be of any commercial value as a hydraulic cementing material.

7 Tricalcium aluminate, when used to replace about 19 per cent of the dicalcium silicate (which is approximately the amount of aluminate present in portland cement), adds somewhat to the strength of the latter at the later periods. This

mixture when used in addition of 3 per cent of plaster gives lower strengths than the silicate alone, as neat test pieces, but as a 1:3 mortar the strengths are higher than any of the dicalcium silicate mixtures not containing the tricalcium silicate.

8 Tricalcium aluminate, when used to replace about 19 per cent of tricalcium silicate, did not add to the strength of the latter, showing rather a slight tendency to decrease it. The addition of 3 per cent of plaster gave higher early strengths but lower later ones.

9 Tricalcium aluminate, when used to replace about 19 per cent of mixture of equal parts dicalcium and tricalcium silicate, increased the strength at 24 hours and 7 days, but decreased it at the later periods. The addition of 3 per cent of plaster increased the strength at all periods.

10 Plaster of paris, when added to any of the compounds or mixtures of those studied, generally increased their strength. This effect is more marked at the early periods.

11 The amount of water of hydration of any of the compounds at any period is not a measure of the strength developed, as the dicalcium silicate at one year with 5.5 per cent water of hydration has a strength almost as great as the tricalcium silicate with 11.5 per cent, whereas the tricalcium aluminate with 26.4 per cent has a strength of less than 100 pounds per square inch.

12 The dicalcium silicate hydrates to a very granular porous mass, which allows of ready egress of solutions, and, while it is chemically more resistant to the action of solutions than the tricalcium silicate, yet it furnishes a great number of voids in which salts may crystallize out of solution, and it is consequently very little able to resist the mechanical action of the "freezing out" (crystallization) of salts from solution.

13 On the other hand, the hydrated tricalcium silicate, with its very dense structure, composed of gelatinous (colloidal) silicate interspersed with crystals of lime hydrate, is probably very susceptible to strains produced by alternate wettings and dryings, colloidal material of this kind being subject to considerable volume change resulting from slight moisture changes.

14 It appears, therefore, that the composition of portland cement should be along lines which would not produce a great preponderance of either silicate. The ideal cement should possibly have an excess of the dicalcium silicate, which would give a not too dense hydrated material, gaining strength at later periods. A lesser amount of the tricalcium silicate would furnish the desired early strength and also overcome the excessive porosity of the dicalcium silicate.

15 It is possible to make a cement that will have the properties of portland cement by grinding together the previously separately burned constituents in approximately the amounts in which they exist in portland cement.

16 The function of tricalcium in the finished cement is somewhat problematical. A cement with less than one per cent of alumina has all the properties of portland cement. Such a cement is, however, not a commercial possibility from the manufacturing standpoint, on account of the temperatures and amount of burning involved. To state, however, that the aluminate in the finished cement is of the nature of a diluent or inert material would be drawing a conclusion which, while justified by the present investigation, requires further confirmatory work.

17 The actual products of the hydration are those noted by Klein and Phillips, excepting as noted before the case of the dicalcium silicate, when apparently during the hydration of this compound lime hydrate is formed.

(*Technologic Paper of the Bureau of Standards*, No. 78, June 9, 1917, 38 pp., 21 figs., *eA*)

MAGNETIC AND OTHER PROPERTIES OF IRON-ALUMINUM ALLOYS MELTED IN VACUO, Trygve D. Yensen and Walter A. Gatward

Data of results of experiments carried out at the University of Illinois to determine the magnetic and allied properties of iron-aluminum alloys melted in vacuo. Only the part referring to the mechanical properties of these alloys is reported here.

In general, it has been found that aluminum in the absence of carbon increases the strength of iron in almost direct proportion to the amount added. Furthermore, aluminum appears to affect the toughness of the iron only slightly, for in alloys containing in the neighborhood of 0.1 per cent carbon, aluminum up to 8 per cent has no marked effect either upon the strength or upon the toughness of the iron, which is especially evident in the case of annealed alloys.

The effect of small amounts of carbon is particularly great upon nearly pure iron and increases its strength about 50 per cent. The strength curves for alloys containing small amounts of carbon will consequently be nearly horizontal, and will raise the curves for the more nearly carbon-free alloys at 4 to 5 per cent aluminum, where the effect of carbon seems to be very small. In general, the effect of small amounts of carbon is to conceal the true effect of aluminum on the mechanical properties of iron.

The writers also compare the effect of aluminum upon the mechanical properties of iron with that of silicon. Up to 4.5 per cent, silicon increases the strength much more than does aluminum. On the other hand, 2.5 to 4.5 per cent silicon markedly increases the brittleness of iron; aluminum has no such effect. Furthermore, silicon beyond 4.5 per cent rapidly decreases both the strength and the toughness, while aluminum continues to add strength to the iron without materially affecting the toughness.

It has also been found that aluminum is more powerful as a deoxidizer than is silicon, for it does not commence to combine with iron until all oxides present are reduced. Aluminum forms a solid solution with iron throughout the range studied.

It has been found that the ultimate strength of a 6 per cent aluminum-iron vacuum alloy is 85,000 lb. per sq. in. in the unannealed state and 70,000 lb. in the annealed state. The corresponding figures for pure iron are 48,500 lb. and 35,000 lb., respectively. (*University of Illinois Bulletin*, vol. 14, no. 22, January 29, 1917, 50 pp., 19 figs., *etA*)

Firing

INFLUENCE OF RADIATION ON FIRE TEMPERATURE, Deinlein (*Zeits. d. Bayerischen Revisionsvereins*, July 31, 1916; *Elektrot. u. Maschinenbau*, 35, p. 10, Jan. 7, 1917, Abstract.)

It is usual to determine the temperature of gases above boiler grates without reference to radiation from the burning surface, it being assumed that all the heat developed by the fuel is in the combustion chamber. If allowance is to be made for the lower temperature of the glowing surface, as compared with that in a furnace protected against radiation loss, it must be remembered that when equilibrium is established, the heat corresponding to the reduction of the combustion temperature is equal to the heat radiated at the reduced temperature. If B denote the weight of calorific value H, L the weight of the air needed for combustion, G the weight of gas, t_1 the combus-

tion temperature, c_p the specific heat content of the gas, then $BH + BLc_pt_L = Gc_pt_1$. Also if t_2 denote the true fire temperature, t_3 temperature of heating surface receiving radiation, C the radiation constant, R the combustion surface, and ϕ a coefficient giving the fraction of the heat radiated from the grate, which falls on the heating surface, then $G(t_1c_{p_1} - t_2c_{p_2}) = C\{[(t_2 + 273)/100]^4 - [(t_3 + 273)/100]^4\}\phi R$. If $\phi = 0$, i.e., if no part of the heating surface is affected by grate radiation and if heat radiated from the grate is not wasted, then $t_2 = t_1$, that is, the actual fire temperature equals the theoretical combustion temperature. The above equation permits of calculation of the radiation ratio $\sigma = (t_1 - t_2)/t_1$ from the measured fire temperature, and hence determination of how much of the calorific value of the fuel is absorbed by radiation to the heating surface. For a given rate of combustion the radiation ratio is practically independent of the fuel. When the rate of combustion is 100 kg. per sq. m., $\sigma = 27$ per cent (ca.); i.e., about 27 per cent of the thermal value of the fuel is conveyed to the heating surface by radiation. At 25 kg. per sq. m. the radiation ratio increases to 44 per cent. The radiation ratio is higher the lower the rate of combustion, and from the relation between fire temperature and radiation ratio it follows that the latter (for a given fire temperature) is higher the better the fuel used. (*Science Abstracts,* Section B—Electrical Engineering, vol. 20, pt. 5, May 1917, pp. 164-165)

Foundry

Thermal Researches on Casting and Molding Sand, Masatosi Okochi

An investigation on the heat conductivity of molding sand.

As an apparatus for the experiment, a wooden box 33 cm. square and 21 cm. deep was filled up with ordinary molding sand. A cylindrical wooden pattern 7.1 cm. in diameter and 15.7 cm. in height was pressed into the sand to half its height at the center of the box. Then molten lead having a temperature of 358 deg. cent. was poured into the mold. Six thermometers were used. The first, nearest to the face of the mold, was a thermocouple, made necessary by the rapid rise of temperature as soon as the molten metal was poured in. The next five thermometers, located respectively at distances of 7 mm. for the first and 20 mm. for the second and equal intervals of 10 mm. for the rest, were of the mercury type.

The molding sand was ordinary river sand with a humidity equal to dry sand plus 10 per cent by weight of water.

Fig. 1 shows data of one of the experiments. This indicates that T_1 rises rapidly as far as about 85 deg. cent. and then rises very slowly until it reaches the maximum of 128 deg. cent. A feature to which special attention is called is that the temperature remains stationary in the range of 96 to 98 deg. cent. This fact was observed in another experiment and is ascribed to the influence of the humidity in the sand. According to the writer, the diminished rate of rise of temperature near the casting is maintained under 100 deg. cent., because a certain fixed amount of heat flowing out of the casting is made use of in evaporating the water contained in the cylindrical layer of the sand between the thermometer and the casting.

In another test there was a very slight amount present, resulting in a temporary rapid rise of temperature. The writer investigates this phenomenon analytically by means of the theory of heat conductivity and comes to the conclusion that castings will prematurely solidify, or, in other words, poured metal will not have sufficient fluidity if there is much humidity in the sand, even if the surface of the mold is thoroughly dried. (*Journal of the Society of Mechanical Engineers,* Tokyo, Japan, vol. 20, no. 47, February 1917, pp. 1-14, 4 figs., *et*)

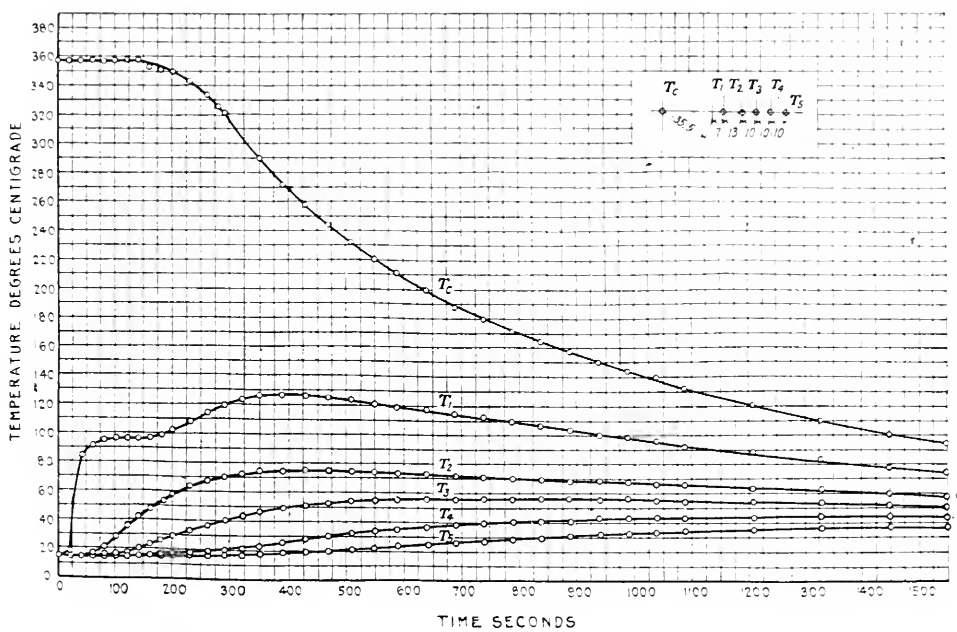

Fig. 1 Curves of Flow of Heat in Molding Sand

Internal-Combustion Engineering

Tractor-Engine Design, C. E. Sargent (Mem.Am.Soc.M.E.)

Paper describing the ideal combination of high compression of less than a cylinderful of air and injection of fuel, expansion to a low temperature and pressure, and control by oil regulation. The writer states that under the most favorable conditions an efficiency of 40 per cent is possible.

In a standard gasoline engine the efficiency at full load is limited first by the low compression, and, other things being

equal, the thermal efficiency increases as the cooling surfaces of the cylinder walls during inflammation. The second loss is caused by releasing the burning gases at an absolute pressure three times as great as it was before compression, eliminating the benefits of expansion so essential for efficiency in other heat engines. The third loss and the greatest limitation to the efficiency of the present engine is the method of reducing the mean effective pressure when developing only a light or idling load. In order to fill the engine cylinder with combustible mixture when its greatest possible output is desired, large inlet valves are provided; yet when less than full load is required, and that is most of the time, the gas is throttled, which not only reduces the compression so essential for efficiency, but puts a back pressure of as much as 10 lb. per sq. in. on the piston. As a result, at least 10 per cent of the power of the engine is required to overcome the braking effect inherent in this form of speed control. Controlling by throttling the intake is a method both simple and cheap, but, as was the case with the early steam engines, is not conducive to economy.

The writer proceeds to the discussion of the use of kerosene as a fuel. He believes that burning kerosene commercially in

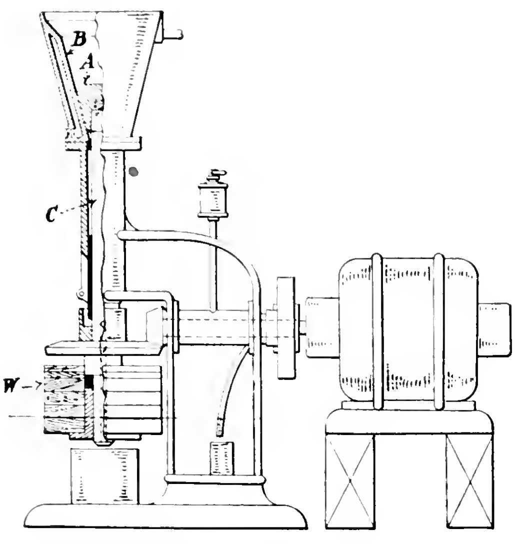

FIG. 2 MACHINE FOR TESTING LUBRICATING OILS

a gasoline engine will never be accomplished until the temperature of the induced charge can be maintained constant automatically, irrespective of the exhaust temperature, compression and cooling effect of throttling. Even if this can be accomplished, the engine capacity will decrease as the temperature is raised to the point necessary for a perfect gas. Regulation by throttling, then, is not conducive to the burning of kerosene.

What the writer suggests is an engine with a 50 per cent longer stroke but of the same bore. Such an engine will weigh a few pounds more than an engine with two-thirds piston displacement, but there will be a net gain of 25 per cent more power from the same fuel. The exhaust will be cooler and the average temperature much less during the working stroke; also the cycle will permit of a speed control that eliminates the back pressure caused by throttling.

The ideal tractor engine (and it is almost real) is one that compresses pure air to a predetermined pressure sufficiently hot to ignite the fuel when introduced, one in which the power and speed can be reduced without introduction of back pressure, in which the fuel used varies with the load and the burning charge is expanded to a greater volume than the air compressed. Every feature embodied in the description of the ideal engine is stated to have been attained. (Paper presented at the Semi-Annual Meeting of the Society of Automotive Engineers, Washington, June 26, 1917, abstracted through *Automobile Topics*, vol. 46, no. 8, June 30, 1917, pp. 889-890, 7 figs., *td*)

Lubrication

TESTING OF LUBRICATING OILS, Hugh K. Moore (Mem.Am.Soc. M.E.) and G. A. Richter

Description of an apparatus for testing of lubricating oils, and data obtained in the tests.

The writers assert that the selection of the most suitable lubricating oil for plant operation depends upon three things: the specific conditions under which the oil is to be used, the cost of lubrication, and the cost of power. This they corroborate by experimental data.

The apparatus used is shown diagrammatically in Fig. 2. It consists essentially of the bearing cone *A*, which is rotated within the conical sleeve *B*, the desired pressure being maintained by a suspended weight *W* on the shaft *C*. The machine is operated by a ½-hp. direct-current motor through a gear drive. The conical sleeve is made high enough to use cones of the different sizes, and is jacketed in order to maintain any desired temperature either high or low at the bearing surface, and also to provide means for bringing the temperature of the bearing to any selected temperature just previous to each successive run in a series.

The power consumption by friction during the operation is measured by means of an ammeter and voltmeter, and the results obtained with different lubricants are directly comparable when the efficiency of the motor is known.

Provision is made for several different methods of testing the oil in question and the writers indicate several such factors. Thus, when the power consumption is a determining factor, the input in watts is plotted against time. In this way the "durability" or "breaking-down" qualities of the oil may be studied. In this case the oil was allowed to circulate in a closed cycle.

TABLE 1 RESULTS OF TESTS OF MACHINE OILS

Number of Oil	Temperatures, Deg. Cent.			Time in Minutes		
	Initial	Final	Increase	Run I	Run II	Average
7	24.0	36.5	12.5	40	40	40.0
13	26.5	30.5	4.0	5	7	6.0
14	22.0	38.5	16.5	47	54	50.5
19	23.0	36.0	13.0	30	32	31.0
23	25.0	38.0	13.0	31	33	32.0
30	23.0	37.0	14.0	35	38	36.5
35	22.0	32.0	10.0	24	24	24.0
36	20.0	37.0	17.0	26	28	27 0

NOTE.—Normal pressure, 1.5 lb. per sq. in. End of groove in cone plugged. No circulation of oil; 3 cc. of lubricant used for each test. Bearing material, brass.

Another method consists in eliminating the oil pump and dropping the lubricant on to the bearing as needed. This determines the consumption of lubricant per unit of time. A third method is to plug the lower end of the spiral feeding grooves leading to the bearing surface, add a certain amount (3 cc.) of oil to the bearing and record the power input each

minute. The machine is allowed to run until the maximum allowable power input is reached, and the power is plotted against time. Such a curve gives information regarding the internal friction (power consumption) and also the "durability" of the oil in question.

In the tests made by the writers it has been found that the oil which stands up for the longest period of time without exceeding the allowable power consumption requires a comparatively higher power input *during* that interval of operation than do the other oils which reach the same predetermined maximum in shorter time. This indicates that although the one oil possesses greater durability, most of the other oils require a much smaller power consumption during their time of operation. Hence, the selection of the most economical oil depends on both the cost of the lubricant and the cost of power. The most economical oil is not necessarily the most suitable, however, since factors such as bearing temperature, gumming and cold test must be considered also.

Data of some of the tests are presented in the form of curves and a table (compare Table 1).

From this table it appears that with the flooded type of bearing, oil 14 is by far the most durable, but its average power consumption is greater than that of the other oils (Fig. 3). On the other hand, oils 19 and 30 last for a shorter interval, but during that interval the average power consumption is much less. Hence, if the cost of power is the deciding factor, oils 19 and 30 are probably more economical to employ than is oil 14, the proportional saving depending on the relative cost of power and of the oil.

The tests referred to in this article were carried out at the Research Laboratory of the Berlin Mills Co., Berlin, N. H. (*Metallurgical and Chemical Engineering,* vol. 16, no. 12, June 15, 1917, pp. 692-694. 3 figs., *ed*)

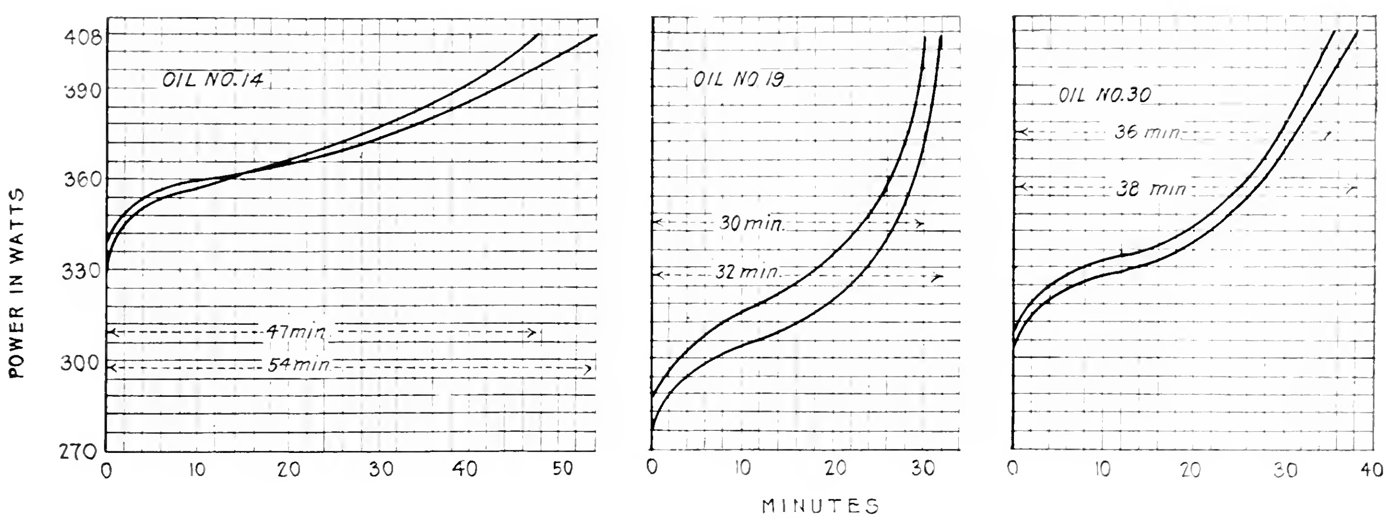

Fig. 3 Curves Obtained in Testing Lubricating Oil

Pumps

Investigation with Screw Pumps, A. Pfeiffer

(*Zeits. ges. Turbinenwesen,* Nos. 17-25, 1916. *Elektrot. u. Maschinenbau,* vol. 35, pp. 10-11, January 7, 1917, Abstract.)

The author presents fresh contributions to the theory and design of screw pumps, based on tests carried out in the Munich Technical Institute. Tests undertaken with and without suction and delivery guide wheels, with sharpened and unsharpened guide and runner-wheel blades, show that this type of pump behaves exactly like centrifugal pumps, and that the fundamental equations of turbine theory are applicable to it. In all the tests it was found that the quantity of water q delivered by the runner wheel $= kn$, that is, is proportional to the speed n r.p.m. Further, if H = delivery head, then $H = k_1n^2$, so that $Q^2 = k_2H$ or $Q = k_3\sqrt{H}$. Since $Q \propto n$, $n \propto \sqrt{H}$, the power N of the pump $= Q\gamma H/75 = k_4H\sqrt{H} = k_5n^3$. This equation and the above ones between Q, n and H are already well known in connection with Francis turbines and centrifugal pumps. The best efficiency of the screw pump (about 57 per cent) is obtained by using a suction guide wheel with sharpened flat blades approximately perpendicular to the direction of rotation, and with an inclination of the runner-wheel blades to the direction of circumferential velocity of $\beta_2 = 30$ deg. Tests without guide wheel show the most favorable blade angle to lie between $\beta_2 = 25$ deg. and 30 deg. The gain in efficiency as compared with the efficiency without suction guide wheel is so small (about 3 per cent) that it is doubtful whether it is worth providing the guide wheel. The influence of a delivery guide wheel on the efficiency of the pump has yet to be determined, the tests made hitherto bearing only on the most favorable blade angle $\alpha_0 = \alpha_3 = 90$ deg. as determined with suction guide wheel alone. As regards the runner-blade angle β_2 giving highest efficiency, it is found that on increasing β_2 from 10 deg. to 50 deg. almost exactly the same delivery on the same head is obtainable, but the efficiency increases up to $\beta_2 = 25$ deg. or 30 deg., and then decreases again. The revolutions per minute decrease to a minimum at $\beta_2 = 30$ deg. (approx.), and thereafter increase again. The delivery head being predetermined, the blade angle β_2 affects only the speed and efficiency of the pump, and *not* the quantity of water delivered. One therefore selects, for each newly designed runner wheel, that value of β_2 yielding the highest efficiency. The efficiency is 55 per cent with $\beta_2 = 25$ deg. and six sharp, flat runner-wheel blades, and apart from the small increase (about 3 per cent) due to addition of a suction guide wheel. If the pump diagram be constructed for this blade angle, the runner-wheel dimensions may be determined for any delivery head and quantity by observing the ratios $b/D = 0.1835$ and $l/D = 0.25$, of blade width and length to runner-wheel diameter. The diagram must be altered when for predetermined

r.p.m. [illegible] exceeds the permissible limit. Results are then [illegible] normally that [illegible] are needed to give the [illegible] calculations. Screw pump wheel may be [illegible] at least [illegible] from each [illegible] should be [illegible] (Science Abstracts, [illegible] vol. 20, pt. [illegible], May 1917, p. [illegible])

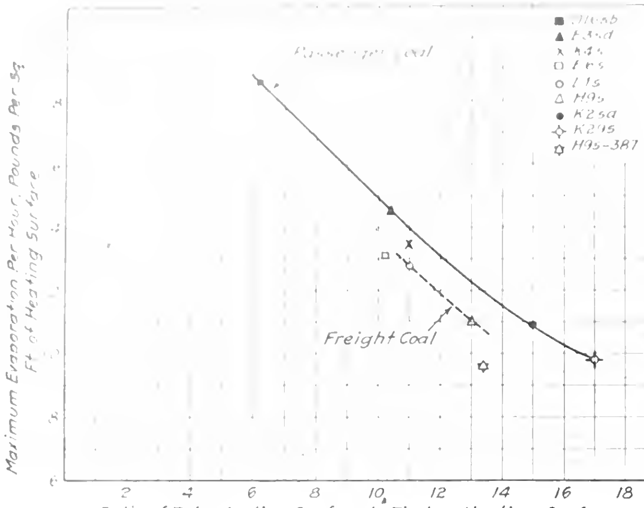

FIG. 4 THE EFFECT OF HEATING-SURFACE DISTRIBUTION ON RATE OF EVAPORATION

Railroad Engineering

MIKADO AND CONSOLIDATION TYPES COMPARED

Additional data (compare THE JOURNAL, May 1917, p. 471) of tests made at the Altoona testing plant of the Pennsylvania Railroad of a Consolidation 2-8-0 type of locomotive as compared with the Mikado 2-8-2 type. The present article reports especially data obtained from the tests on this latter type.

The tests were all run with a wide-open throttle, the speeds ranging from 7.2 to 31.1 miles per hour with cut-offs from 20 to 80 per cent of the stroke. The coal used was run of mine, as used in freight service on the Pennsylvania, with the heating value between 13,600 and 14,300 B.t.u. per lb.

As regards the *boiler performance*, the maximum steam temperature obtained was 590.6 deg. fahr., the superheat then being 207 deg. From curves given in the original article, it is seen that, as a rule, the smokebox temperatures are below 550 deg., indicating the efficiency of the heating surfaces. On the other hand, the firebox temperatures above 2400 deg. for rates of firing above 85 lb. per sq. ft. of grate per hour are unusually high, and the whole range of firebox temperatures is greater than usual.

From comparisons of tests with seven locomotives at the testing plant, it is apparent that the maximum evaporation is closely related to the fire area or the area of all the tube openings. These seven locomotives indicate that under normal conditions each square foot of fire area of the tubes should give a maximum evaporation of about 7000 lb. of water per hour. But with the improved Consolidation locomotives (H9s) a maximum evaporation of only 5308 lb. per sq. ft. of fire area of tubes was obtained. This was due to certain features of construction of the Consolidation locomotive firebox.

Fig. 4 indicates, however, how the relatively large firebox heating surface makes possible a high rate of evaporation per unit of total heating surface.

Other data obtained in the test (compare Fig. 5) indicate the equivalent evaporation per pound of dry coal. The results for the Consolidation are considerably below those for the Mikado, as the latter on a basis of heating surface shows a range of evaporation between 3 and 16 lb. of water per sq. ft. of heating surface.

Very interesting curves of boiler efficiency are shown in

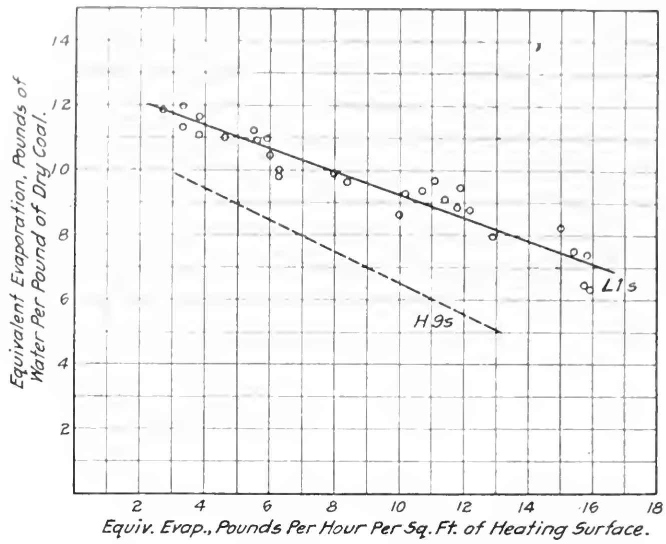

FIG. 5 RELATION OF EQUIVALENT EVAPORATION PER POUND OF DRY COAL TO THE RATE OF EVAPORATION

Fig. 6. They bring out how rapidly the efficiency of the Consolidation boiler falls off compared with that of the Mikado

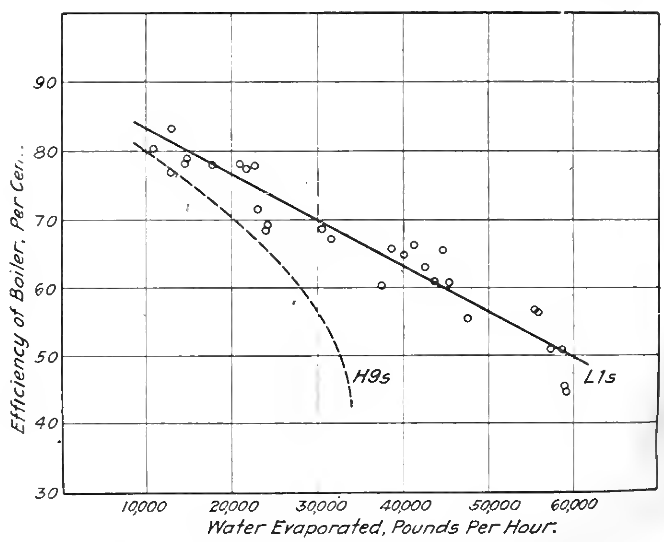

FIG. 6 VARIATION OF BOILER EFFICIENCY WITH EVAPORATION RATE

at rates of evaporation above 2500 lb. per hour. It is stated that for the Mikado the firing rate was between 20 and 175 lb. per sq. ft. of grate, the efficiency of the boiler ranging between 80 and 45 per cent. The maximum evaporation of the Mikado's boiler was 6990 lb. of water per sq. ft. of fire area through the tubes, a rate never before obtained at the test plant.

Engine Performance. The indicated horsepower of the Mikado covered a range between 356, with 20 per cent cut-off and a speed of 7.2 m.p.h., and 2837 at 60 per cent cut-off

and a speed of 31.7 miles per hour. The best steam performance of the Mikado is at a rate of working about 2000 i.hp., the steam rate varying between 19 and 24 lb. The maximum horsepower obtained from the Mikado is greater than that obtained from any other freight locomotive ever tested at the Altoona plant. The curve in the original shows the economical relation of the water rate to the indicated horsepower to be in favor of the Consolidation, probably due to the higher degree of superheat obtained.

On the other hand, in the matter of back pressure the Mikado shows a minimum of less than one pound and a maximum of 16 lb. At the maximum hp. of the Consolidation, which was 1800 in these tests, the back pressure is 8 lb., while the Mikado shows but 4 lb. at the same power. The larger exhaust nozzle of the Mikado (38.3 sq. in. as against 30.9 sq. in. for the Consolidation) probably has an important bearing on this result. Engines of the Mikado type use from 18,500 to 26,100 B.t.u. per i.hp-hr. and convert into work from 9.7 to 13.7 per cent of the heat supplied. In plotting the thermal efficiency of the engines it has been again found that they are the most efficient when developing about 2000 i.hp.

Dynamometer tests have also shown the advantage of the Mikado over the Consolidation for all classes of freight service. In fact, the drawbar pulls obtained indicate that it gives 25 per cent greater pulls at 10 m.p.h. and 60 per cent greater at 30 m.p.h. (Pennsylvania R. R. Testing Plant Bulletin, No. 28, abstracted through the *Railway Age Gazette*, vol. 62, no. 23, June 8, 1917, pp. 1187-1191, 13 figs., *eA*)

Design of Locomotives with Interchangeable Parts

The St. Louis-San Francisco Railway has recently received forty locomotives of modern and heavy types from the Baldwin Locomotive Works, and advantage was taken of the fact that this large order was given at one time. Of these forty locomotives, ten are of the Pacific type for express passenger service, and thirty of the Santa Fe type for heavy freight service. In many respects the two types are similar in construction, and interchangeable details are used when practicable.

Thus, in the case of the Santa Fe locomotives, the machinery and running-gear details are similar to those of the passenger locomotives. The piston valves are interchangeable, and as the frame width and driving journals are of the same dimensions, the driving boxes and shoes and wedges interchange. The same is true of the rear trucks.

The valve gear of the Pacific-type locomotives is of the Baker type and is controlled by the Ragonnet power reverse mechanism. An interesting detail is the pistons, which have rolled-steel heads of dished section with bull rings and packing rings of Hunt-Spiller metal. (*Railway Review*, vol. 60, no. 25, June 23, 1917, pp. 863-868, 9 figs., *d*)

New Electric Locomotives of the Pennsylvania R.R. Co.

In anticipation of the application of electric power to the portion of its main line traversing the summit of the Allegheny Mountains between Altoona and Conemaugh, Pa., the Pennsylvania Railroad has constructed a large electric locomotive.

This locomotive is designed to operate on 11,000-volt, single-phase, 25-cycle current from an overhead trolley. The phase converter changes it to three-phase current for the use of traction motors. These motors, of which there are four, have a rating of 1200 hp. each, giving the locomotive a capacity of 4800 hp. Two motors are mounted on each truck frame; they are geared to a jackshaft impelling the driving wheels through connecting rods, the springs in the gears of these jackshafts being so adjusted as to give the effect of a solid gear up to a tractive effort equivalent to 25 per cent of the weight on drivers. Therefore, under all ordinary conditions, the effect of a solid gear is obtained. (This jackshaft is illustrated in the original article.)

Each truck receives power from its two motors through a spring gear wheel on each side mounted on a jackshaft. Each gear wheel is connected to the three drivers by the usual side rods and the remainder of the drive and running gear is similar to those used for steam locomotives. The spring gear for each truck is of the three-point-suspension type, one point being over the pony truck and the other two points over each frame, consisting of equalizers over each box, elliptical springs between journals and helical springs outside the first and third journals.

The articulation between the motor trucks is of a construction involving a pedestal adjustment to the car center sills. The lower ends of the pedestal legs are connected by means of a tie bar, permitting each truck to rotate around the axis of the center plate without restriction. All bearing surfaces in the articulation are plated with manganese steel. The design is such that pulling and pushing strains between drawbars carry through the trucks and articulation in a direct plane 34½ in. above the rail, so that the cab is entirely relieved of these strains. (*Railway Review*, vol. 60, no. 25, June 23, 1917, pp. 870-873, 7 figs., *d*)

Tests of Corrugated Culvert Pipe under a Sand Bed, Geo. L. Fowler (Mem.Am.Soc.M.E.)

Description and data of tests of pressure produced by a bed of sand. These tests were made in several ways, described in detail in the original article.

The first tests were made with wrought-iron pipes 2, 4 and 6 in. in diameter, 18, 16 and 21 in. long. Each was fitted with a flange coupling at one end, to which a similar flange could be bolted. A sheet of cheap white wood-pulp writing paper was bolted between the coupling flanges. This formed a diaphragm closing the pipe. Wooden plungers were provided that fitted loosely in the pipe and by means of which the pressure could be applied to the paper diaphragm. The amount to burst the diaphragm was noted. Then a fresh diaphragm was put in place and covered to a depth of 1 in. with dry sand. The pressure was again applied and the amount noted. In this way were determined the loads required to burst the paper diaphragms and the results have been plotted in a diagram of bursting pressures, assuming that a circle at the center carrying 60 lb. was the pressure transmitted to the paper and that the annular space outside of it represented the pressure carried by the arching of the sand.

In the diagrams, of which Fig. 7 is given as an illustration, the line B is drawn from the ends of the percentage lines at 3½ diameters of such diagram to the edge of the pipe. The angle which this line B makes with the side of the pipe is 6 deg. 58 min. 37 sec. for the 6-in. pipe, 6 deg. 57 min. 56 sec. for the 4-in. pipe, 7 deg. 2 min. 39 sec. for the 2-in. pipe, or a total variation of 4 min. and 43 sec. This is a very close agreement and may be considered as an approximation to the angle of arching sand. Further, it tallies closely with the investigations of J. A. Jamieson on grain pressure.

These investigations were supplemented by tests with different arrangements in which lateral thrust of the sand under

a superimposed load and the vertical pressure of the sand were recorded by dynamometers. As regards vertical pressure it was found that the bottom pressure decreased with the depth of sand, but for any given depth the ratio of pressure is nearly constant and rises on approximately straight lines as in the other tests above referred to.

However, as regards the pressure of the sides, an entirely different state of affairs was found. With the depth of $10\frac{1}{2}$ in. of sand above the bottom and $4\frac{1}{4}$ in. above the center of the side dynamometers, there was a steady rise in the lateral

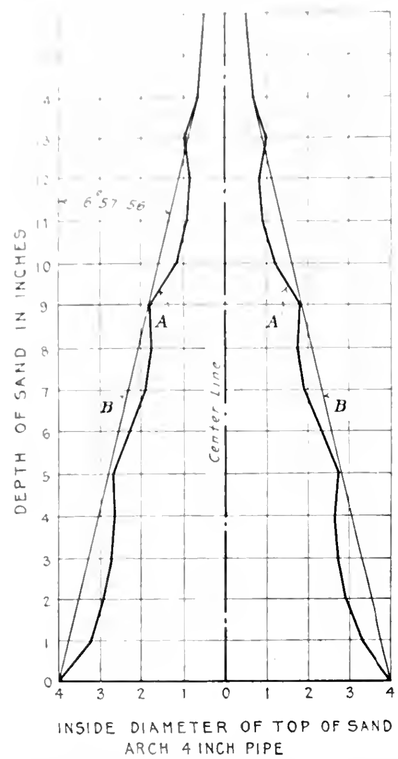

Fig. 7 Diagram of Bursting Pressures of Paper Diaphragm in Tests of Corrugated-Pipe Culvert

thrust as the pressure increased. But when the load was removed from the top the compacted mass of sand continued to exert its side pressure and there was an initial load, and after the depth had been increased and loads were applied there was practically no increase of pressure on the side. In other words the lateral thrust rose rapidly to its maximum under a comparatively shallow depth of sand and then remained practically constant for all increases of depth. It appears from this that on a slightly yielding bottom like that of the type of a corrugated culvert the sand arches and the bottom are relieved of the load.

These tests were checked by another series of tests with a more elaborate equipment. These new tests have emphasized in a marked manner the importance of having the material well tamped against the pipe. It was further found that the sand flows and transmits its pressures without much delay. The influence of a vertical load does not extend very far laterally. During the building up of high pressures the sand yields.

In general, these experiments have corroborated the work of J. C. Meem, who found that in an excavation the lateral pressure increased very rapidly from the top down, reaching a maximum at a point dependent on the angle of repose of the material and then decreasing. It appears that after a certain, as yet undetermined, depth has been reached there can be no further load put upon a culvert pipe by an increase of the depth of cover. And furthermore, such an increase of depth serves directly to protect the pipe against any burden due to an increase of surface loading.

The question next investigated was that of the behavior of culverts under a loading similar to that applied in railway service, where, instead of the application being made on a broad platform covering a considerable area, it is applied through ties of limited width and separated by intervals in which no load is applied to the material. It was found that with the load applied to broad platens, the increase of loading was stopped when the pipe had been deflected by approximately one inch, it being quite evident that the platen would carry a greater load. With the load applied on the ties, the increase was stopped automatically by the ties sinking in the sand and thus refusing to carry more. The result was that the distortion of the pipes under the greatest pressures obtainable was very slight.

These tests have established the fact that under the heaviest load that can be applied to the ties of a railroad track by the wheels of any existing locomotive or car, a 24-in. corrugated culvert pipe having proper depth of corrugation and thickness of metal and buried under a cover of 24 in. of dry sand cannot be deflected beyond its elastic properties of complete recovery of its shape when the load is removed. (*The Railway Gazette*, vol. 26, no. 24, June 15, 1917, pp. 687-691, 7 figs., *e*)

Pennsylvania Locomotive of the Decapod Type

In December 1916 the Pennsylvania Railroad built at the Juniata shops a Decapod locomotive having unusual features of construction, and, among other things, a total weight of

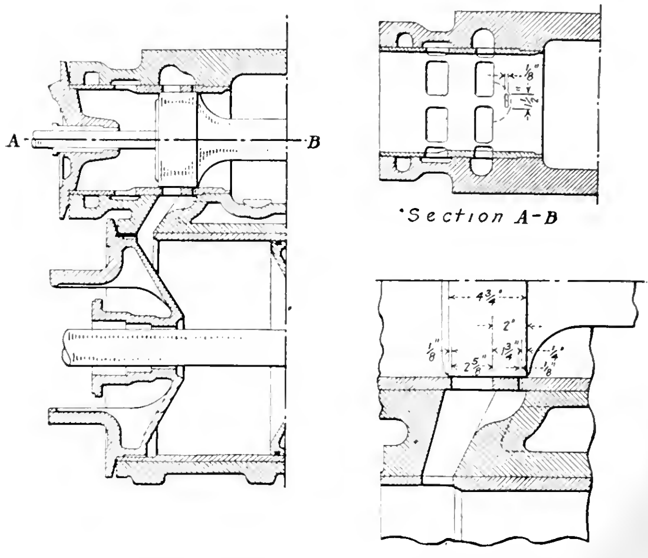

Fig. 8 Details of the Auxiliary Starting Port

366,500 lb., a weight on drivers of 344,500 lb. and a tractive effort of 80,640 lb.

Instead of operating at a maximum cut-off of approximately 90 per cent, the valves have been given a steam lap of 2 in. and a maximum cut-off with a reverse gear in the corner of 50 per cent (for reasons explained below).

The desire to secure a maximum tractive effort in proper relation to the weight on drivers necessitates the use of much larger cylinders than are required where 90 per cent cut-off can be obtained. Hence, the cylinders are made 30 in. in diameter by 32 in. long, the boiler pressure being fixed at 250 lb.

per sq. in., so as to take care of clearance limitations which prohibit a still further increase in the diameter of the cylinders.

The use of a 2-in. steam lap necessitates some auxiliary means of admitting steam to the cylinders when the locomotive is standing, in order that it may be started from any position of the crankpins. This difficulty was overcome in a very simple manner. Pockets about 1¾ in. deep are cored out of the inside edge of each steam port in the valve chamber, two in each port. Two ports, ⅛ in. wide and 1½ in. long, are cut through the valve chamber opposite the openings into the pockets in the cylinder casting. This arrangement is shown in Fig. 8, from which it is seen that the auxiliary ports are so placed that their steam lap is ¼ in. These ports serve merely to move the engine until the main ports are opened.

The purpose of the use of 50 per cent cut-off is to eliminate the range of cut-offs within which the water rate of the cylinder is excessive, thereby making possible an increase in the ratio of cylinder power to boiler capacity. (*Railway Age Gazette,* vol. 62, no. 24, June 15, 1917, pp. 1241-1243, 4 figs., *d*)

Analysis of the Axle-Generator Belt Problem

The *Railway Electrical Engineer* announced in April a competition for papers presenting an analysis of the axle-generator belt problem. The two papers which received the first and second prizes, respectively, are published in the article of which this is an abstract.

J. R. Sloan, Engineer Electric Car Lighting, Pennsylvania Railroad, gives the following list of factors affecting belt life in axle-generator service:

1 Lost motion in running gear of cars
2 Type of generator suspension
3 Track conditions and water conditions
4 Size of pulleys
5 Alignment of pulleys
6 Belt fasteners and their application
7 Character of belt.

The writer then discusses in detail each one of these factors. The size of pulleys used is an important factor in the life performance of the belt; the smaller the diameter of the pulley, the less the area of contact and consequently the greater the belt tension for the same amount of power transmitted. Also the smaller the pulley, the greater the relative motion of the fibers of the belt, and the greater the tendency toward internal wear due to friction of the fibers of the belt on each other. To obtain maximum belt service, therefore, the pulleys should be as large as possible.

As regards belt fasteners and their application, the writer states that all types of belt fasteners known to him, with the exception of one, weaken the belt by cutting the fibers and are objectionable in that respect. They have also the disadvantage of introducing a rigid section in the belt.

The writer has a record of approximately 15,000 individual belts, of about thirty different makes, of widths from 4 in. to 6½ in. and plies from four to six, on which various types of fasteners were used. These belts were rubber, friction and canvas. This record shows car number, date and place of application, and date and place of application of the next belt, and the Car Record Office furnishes the mileage between the two dates and places as above. The belts were practically all bought under the same specifications and the record has been carefully studied with a view of determining what make and type of belt is the most suitable.

The evidence is, however, too contradictory to enable one to say that any one make of belt is best, although it has made it possible to eliminate the purchase of certain belts that were decidedly poor. It has also shown that, with operating conditions as they are, a 5-in. 5-ply belt will give service at the least cost per thousand miles. However, the more these records are studied, the more convinced the writer becomes that the reason for low belt mileage is not so much the quality of the belt used as it is the effect of the other causes enumerated above, and it is believed the fastener is the greatest factor, with rough handling of cars next. The perfect belt fastener for axle-generator service has yet to be devised.

The writer's idea of a suitable belt for axle-generator service is a 5-in. 5-ply belt, the yarn being Sea Isle long-fiber cotton woven to weigh not less than 28 oz. per sq. yd., and with the edges straight, the variation in width not to exceed 3.5 per cent plus or minus.

Each inch of width of each ply should have a tensile strength of at least 200 lb. and the plies should be cemented together with a friction of at least 18 lb. per in. of width when tested at a speed of 20 in. per min. The outer surface should be covered with a 1/32-in. layer of good-quality rubber. The complete belt under test load should not stretch over 1½ in. in 18 in.

J. R. Davis, Electrical Engineer of the Baltimore & Ohio, in discussing the same problem states that his experience has shown that alignment and maintenance of suspensions and trucks is a more vital factor in affecting belt life than the difference between the two general types of suspension. In addition, the kinds of belting and fasteners used are also important factors affecting belt maintenance. The following belt-performance data with various types of suspensions are based on an average extending over a period of more than two years. The number of equipments shown, however, are those at present in service.

Table 2 Data on Axle-Generator Belting, Baltimore & Ohio R. R.

Type of Suspension	No. of Cars	Average Belt Mileage
TRUCK SUSPENSION		
Two-point swinging link	44	14,300
Parallel link with belt passing over end frame and under brake beam	24	21,500
Parallel link with open-end truck and inside-hung brake beam	8	35,000
Inverted link	33	15,900
BODY SUSPENSION		
Variable-speed generator with constant-tension device	60	16,900

The experience so far obtained does not permit of reaching any definite decisions with reference to types of suspensions and kinds of belting, but indicates the following:

1 The belting and belt fasteners that have given very satisfactory results with truck-mounted generators may not be at all adapted for body-mounted generators.

2 To secure the best results, with respect to belt life, with body-supported generators of constant-speed type, a belt of special quality is required which should, however, give equally satisfactory results with other types of equipment.

3 Truck-mounted generators of either the two-point swinging type or parallel type, with open-end truck and inside-hung brake beam, thus eliminating all possibility of belt interference, will give longest belt life.

4 The advantages of the body-supported generator as compared with the truck-supported are that it has greater ease for

inspection and making repairs, especially under adverse weather conditions; materially reduced maintenance cost of [illegible] incidental thereto, which will probably be [illegible] greater importance than any differences that [illegible] belt life. Steam Engineering

Construction and Operation of Boilers for Intensive Service, F. Munzinger

(*Zeits. Vereines Deutsch. Ing.*, vol. 60, pp. 933-939, Nov. 11; 958-962, Nov. 18; 1001-1006, Dec. 2, and 1017-1021, Dec. 9, 1916)

The author considers modern boiler practice from the standpoint of cheapness obtained by better utilization of constructional materials and higher stressing of the finished equipment. The influence of turbine development on boiler practice has been far-reaching. The possibility of concentrating very high power in single, compact units led to the development of two-story boiler houses; large overhead bunkers gave way to small pockets directly coal-handling plant became sufficiently reliable; this eliminated much heavy ironwork and saved greatly on the size and cost of buildings. By using comparatively small and cheap feed heaters it became possible to add to overall efficiency while cutting away that portion of the boiler which would otherwise extract heat from the cooled flue gases. A good example of the nature and rapidity of progress in boiler practice is to be found in the power stations erected by the A. E. G. during the period 1908-1912. The boiler-house designs submitted in 1906 contemplated a cheaper construction than had hitherto been employed, and these plans were further improved in respect of the space occupied by feed heaters. By building the economizers of wrought instead of cast iron, and by making them an organic part of the boilers, sufficient saving was effected to outweigh the probably shortened life of the economizer tubes; also, loss in the pipe line was reduced by the shorter pipes and higher steam velocities possible. The first cost of the whole boiler installation and the invariable losses are both reduced considerably. Interesting data concerning boiler installations in South Africa, at Brakpan, Simmerpan, Roshervilledam, and Vereeniging, respectively, are as follows: Date of construction, 1908, 1909-1910, 1911, 1912; weight of boiler, feed heater, and induced-draft equipment, 405, 405, 306, 323 kg. per sq. m. of boiler heating surface; total weight of boiler equipment and steelwork of boiler house, 576, 546, 344, 400 kg. per sq. m. of boiler heating surface; ground space of boiler house, 0.292, 0.287, 0.204, 0.204 sq. m.; space occupied by boiler house and bunkers, 5.70, 5.24, 3.05, 2.24 cu. m. per sq. m. of boiler heating surface in all cases. The cost of boilers in a modern central station working at a high load per unit of heating surface is 25 to 30 per cent of the total installation cost, and the constant losses of the boiler are more serious with the usual type of load curve than in works with nearly constant load. In the case of a public supply station, even the shortest interruption of supply must be avoided at any cost. As a consequence, special desiderata in the boiler equipment are maximum efficiency, adaptability to load variations at minimum capital expense, great reliability and liberal reserve capacity.

Boilers are almost unique in the amount of careful attention which they demand in respect to often contradictory requirements, and there cannot be a boiler which is at once the most desirable for such industrial service as that of a paper mill, and also for central-station work. Too much importance is often attached to a high thermal efficiency, apart from other considerations. The total cost of one ton of steam must be a minimum, and this includes interest and depreciation on the first cost of the boilers with buildings and site, and the cost of coal, repairs, maintenance, and attendance. High efficiency increases in importance with rising price of fuel and longer working hours, but the other factors in "total cost" should never be overlooked. Good efficiency, high steaming capacity, and compact construction are often found in boilers which have serious organic defects, and when an apparently good boiler is discovered, it often happens that some part of the equipment or construction is very unsatisfactory (e.g., defective brickwork or bad grate bars in an otherwise satisfactory boiler).

The steaming capacity, referred to heating surface, has been so much increased that a continuous output of 35 to 40 kg. per sq. m. is nothing unusual in modern boilers. To allow for the heavier depreciation and repairs, the cost of these items should be referred to the weight of steam produced and not to the heating surface. This applies particularly to the fire arch and lining of the combustion chamber. A characteristic of well-designed high-power boilers is the flat course of the upper portion of their efficiency curve, due to the large heating surface exposed to radiation over the grate and to the large economizer surface (as compared with boiler heating surface). In boilers with inclined tubes, radiation from the large volume of luminous flame in the combustion chamber is an important factor, and gives additional efficiency, which is, however, offset to some extent by the better transfer of heat by contact when the gases are guided through and through the tubes by baffle plates. Test data relating to six modern high-power boilers, with heating surfaces ranging from 344 to 770 sq. m., economizers and induced draft, show the evaporation to range from 18 to 53 kg. per sq. m. of heating surface per hour; boiler efficiencies (including superheater) from 67.3 to 81 per cent; and overall efficiencies from 79 to 90 per cent. Tests on two boilers, taken for 24-hour periods without the knowledge of the boiler crew, showed the efficiency to be only about one per cent lower after six months' service than the value obtained during the acceptance test. Heavy brickwork mounting causes an apparent decrease in efficiency during the period at the beginning of the day and a corresponding increase at night after the load decreases. An A. E. G. boiler with plate casing, however, withstood load reduction from 6000 kw. to 2800 kw. in ten minutes without blowing off, although the pressure all day was within 7½ lb. of the safety-valve setting.

The water connections between the bottom drums of vertical and inclined water-tube boilers should be so arranged that the circulating water passes through the lowest parts of the drums. Where boilers have to be put in and out of service very frequently, provision should be made to pass steam from the mains into the lower drums so as to equalize heating and reduce unbalanced stresses. The author shows diagrammatically the water and steam circuits in various boilers, and discusses the relative merits of the several arrangements. Where very reliable load has to be supplied, there is some advantage in preheating the feedwater on part of the boiler heating surface before mixing it with the remainder of the water; part of the boiler then serves the function of economizer. The author considers it of minor importance whether water tubes are straight or curved; it is a little easier to inspect straight tubes, but it is not easier to form a correct estimate of the thickness of scale; probably the chief advantage of straight lines is the simplicity of renewals. In boilers with separate steam and water connections between the upper drums, the steam velocity

may range from 2½ to 8 m. per sec., but if a common connection for water and steam be used, the velocity must be reduced to 0.8 to 2½ m. per sec. (approximately). When water in the front drum is very much agitated by severe working of the front tubes, steam in the front drum is apt to be very moist, and it is given an opportunity of separating if the flow to the rear drum is subdivided and at moderate speed. Moderate steam velocity also favors uniform pressure and water level in the two drums: if any marked pressure difference exists, pressure variations with fluctuating load are transmitted partially through the water tubes, disturbing the water circulation and producing wet steam. Owing to the violent agitation of water in the top drums of water-tube boilers, special measures are generally needed to secure dry steam. The author recommends that in all cases a separate, large steam accumulator should be provided between the top drum and the steam main. The greater the heating surface, the larger must be the top drums, steam accumulator, and all internal water and steam connections of a vertical-tube boiler. It is not enough merely to change the grate surface in order to change the steaming capacity. If properly designed and constructed, this type of boiler will give as dry steam as double-header boiler.

In large central-station boilers an automatic feed regulator is generally installed between economizer and boiler. The economizer is then exposed to all shocks in the feed pipe, and if of cast iron is particularly liable to be damaged. It is preferable to place the regulator in front of the feed heater, especially as this does not affect the actual feeding in any way. Quick-acting control valves naturally cause greater pressure rises than slower valves; air vessels reduce the shocks caused by quick-acting valves, but it is better to use a slow-acting valve. Pressures up to 25 atmospheres were reached in front of a quick-acting valve controlling the feed to a large boiler through a 100-m. pipe line. Higher water velocities and more severe stresses are reached with intermittent than with continuous feed. Steam generated in the feedwater can escape more easily if the control valve is not between economizer and boiler.

The author gives the results of measurements by optical pyrometer on various types of boilers at various loads. The firebox temperatures range from 1067 deg. to 1500 deg. cent. The combustion space of vertical-tube boilers is generally much loftier than that of double-header water-tube boilers, and in order to bring the flames into close contact with the tubes, large arches were often placed over the grate in the early vertical-tube boilers. By preventing direct radiation to the heating surface, such arches increase the temperature of the combustion chamber, favoring complete combustion, but shortening the life of the refractory bricks. In a certain case the furnace lining became useless after 600 working hours due to this cause. The better heat transmission by radiation in an open combustion chamber compensated for the less favorable transmission by contact.

Flue passages must be such that there is maximum "washing" of the heating surface, with minimum loss of draft. Sharp turns, and pockets in which explosive gas mixtures might collect, are to be avoided. Easy access should be provided to rivets, flanges, etc., and for cleansing. The lower drum should foul up very slowly. Manholes should be properly sealed and protected from the heat; suitably placed inspection posts are very useful, as also are openings for pyrometers. Staggered tubes are useful, especially in the back rows, so long as renewals are not made difficult. Tubes should not be set at too small pitch, otherwise the cost of construction is increased, and even flow of gases and good heat transmission are made impossible. The great difference in output per sq. m. of heating surface of economizers differing little in construction is due to the more or less complete distribution of gases over the heating surface. Consequently it is difficult to establish any definite relationship between feed heating performance and gas velocity. Provision should be made for varying the effect of the superheater at will; refractory plates should be used, and a temperature regulator is desirable where the quality of the coal varies much and often. By placing the superheater in parallel with part of the heating surface, the steam temperature may be kept nearly constant within a wide range of load. The superheater should be surrounded by boiler heating surface rather than by brickwork, otherwise very high steam temperatures may be reached after a sudden decrease in load.

A good fireproof material for boiler masonry must resist high temperatures without melting or softening. Quartz tiles resist intense heat, but are sensitive to temperature changes, and do not resist the fire so well in the direction of their grain as perpendicular thereto. Firebricks composed of SiO_2 and Al_2O_3 are used more commonly. Classification of such bricks as acid or basic is lax and unreliable. A small percentage of such fluxes as Fe_2O_3, CaO, MgO, K_2O lowers the heat-resisting value of the brick. Quartz additions always lower the melting point. Undue importance should not be attached to high Al_2O_3 content, nor should the Seger cone number be taken as a complete index of refractoriness. Steel Plant

Relative Methods of Forming Steel by Pressing, Hammering, or Rolling, John Lyman Cox

Paper presenting comparative data on effectiveness and quality of product in very heavy work with hammers and presses. The paper is partly historical.

With the exception of the tube, which is generally made solid, the larger forgings for heavy artillery are usually made hollow, as are marine shafts and other forgings when desired of especially high quality. As it is difficult to manipulate under a hammer, in upsetting and punching, blocks too heavy to be handled on levers, it is customary to bore the ingot with a hole of considerable size and cut from it a hollow block of the proper weight for the job. This involves a considerable waste of material, which may, however, be avoided by proper arrangements.

The width of a hammer anvil block is not great, and if the forging is heavy, it is, in practice, necessary to use an ingot of initial section sufficient to give the requisite weight in the short length that will go between the checks of the mandrel housing, for upsetting of heavy blocks under a hammer is impracticable.

The employment of ingots of large cross-section being objectionable for various reasons constitutes one weakness of the hammer, namely, it cannot make great hollow forgings such as are easily producible under the press. It might be urged that an anvil of a special design would permit the use of long billets of less diameter, but the low, unsupported mandrel will not withstand the impact of hammer blows. A 14-in. mandrel on a span of 45 in. to open a hole some 2 in. is about the limit for a hammer.

When made under a hammer of ample power, forgings show test results practically identical with press forgings made

under the same conditions, so long as neither is expanded, but beyond the point where hammer expansion is possible, the advantages are altogether with the press.

Lest it be thought that too much stress is laid upon the advantages of expansion in the manufacture of hollow forgings, the writer cites an experience of the Midvale Steel Company with jackets for a lot of 12 in. steel coast defense mortars. These were rather short forgings drawn on about a 19-in. mandrel and bored originally with a 20 in. hole. The hole was so small that it had been decided expansion would not pay. But on testing, the jackets gave a great deal of trouble, and it was concluded to bore the ingot with a 11.5-in. hole, expand on a 14 in. mandrel to 16.25 in. in diameter, substitute a 15.75-in. mandrel and expand to 20 in., and after this draw the forgings in the V die as before. Expansion of the whole increased the outside diameter by only $1\frac{5}{8}$ in., giving that much reduction in the V-dies, but on the other hand, the amount of testing was reduced to 21 per cent.

The danger in solid hammered work is always that for economy's sake too light a hammer is used, and the forging left with an imperfectly reduced grain size towards the center.

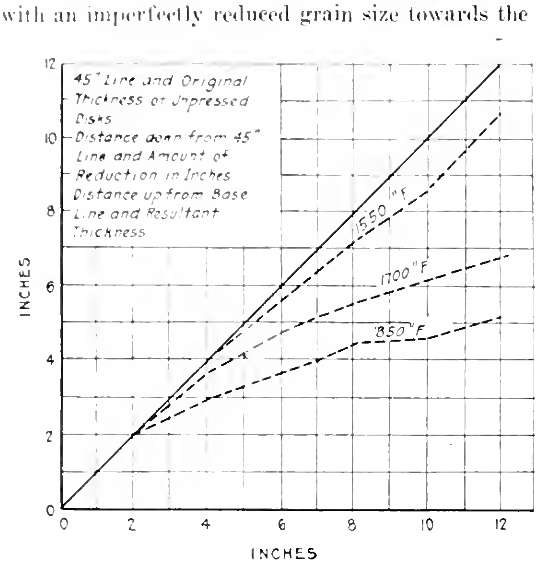

Fig. 9 Relative Effects of Various Thicknesses and Temperatures from Experiments on Forging Pressures

The pressure produced by a hammer is directly proportional to the effective stroke and inversely proportional to the contact area of the dies and to the distance through which the pressure is exerted. The pressure exerted by a press is independent of the stroke, is definite in amount, equaling the net power of the tool divided by the contact area of the dies and the piece being forged.

In press forging the work is turned up after every stroke, thus always presenting a new and smaller contact surface. In cogging down an ingot under a hammer before rounding up begins, several blows are usually struck in the same spot until fear of lapping stops them. Due to the inertia of the part of the ingot beyond the die at the instant the blow falls, there is a tendency to cock up the end of the piece, and the tendency in practice is to let it occur and for the hammer die to cut in more deeply on one side of the ingot than on the other, gradually throwing the axis of the forging out of the axis of the ingot. This does not occur in the press.

As regards the limits of effective reduction, the writer calls attention to the fact that friction between press-die faces and their work is very great, while the longer time of contact as compared with the hammer tends to chill the surface of the forging and to prevent the flow along the die faces. This results particularly in a reduction of the effective thickness of the forging and the increase in the pressure required to forge it. The article gives a table containing ratios of thickness to pressure; in addition to this, Fig. 9 is given, showing graphically the relative effects of the various thicknesses and temperatures employed in a recent series of experiments. The important influence of thickness is corroborated by two full-sized experiments, where, in upsetting at full forging heat 37 in. octagon slices from 43 in. to 13.5 in. in length, it required 8700 tons, which, figured on the areas of the final diameters of 59 in. and 65 in. at the die faces and center, respectively, gives 3.18 tons per contact inch and 2.6 tons at the center. In upsetting the 48-in. round from 45 in. long to 33 in. long, it took only 1.4 tons per sq. in. of contact area and 1.3 tons per sq. in. of median area, on account of the extra thickness of the piece.

With all its advantages, such as convenience of handling and absence of shock, the press has two failings, due to its lack of impact: first, it is harder to get rid of scale, and second, it cannot strike in a mold as large a forging as a hammer its equivalent in other respects. At the Midvale Steel Company they consider a 500-ton press the equivalent of a $2\frac{1}{4}$-ton hammer; a 1200-ton press the equivalent of a 10-ton hammer, and a 2500-ton press the equivalent of a 25-ton hammer. Yet the $4\frac{1}{2}$-ton hammer can make drop forgings which are beyond the power of a 1200-ton press, and a $2\frac{1}{2}$-ton hammer can about equal it.

The rest of the article is devoted to a comparison of forged and rolled rounds and to armor-plate practice. (*The Blast Furnace and Steel Plant,* vol. 5, no. 6, June 1917, pp. 252-257, 8 figs., *e*)

Thermodynamics

Concerning the Absolute Value of Entropy and Energy, E. Ariès

The writer asserts that there is an initial stage common to all bodies and convenient to be used as a starting point for measuring their entropy and energy. For all bodies this state is defined by the following conditions: The body is at zero absolute temperature, is condensed to the state of saturation, and not subject to any pressure. Any finite increase of volume to which it may be subjected at constant temperatures results only in the body being forced to emit at fixed pressures ($T = 0$, $p = 0$) an inappreciable quantity of vapor (which cannot be measured), so that the entropy and energy of the body remain nil.

On the other hand, every reduction of its volume obtained by means of compression at constant temperature increases its pressure and energy which have at first been nil and now become positive, but its entropy remains at zero. In short, a body when at zero of absolute temperature has an entropy equal to zero and an energy either nil or positive, no matter what may be the pressure to which it is subjected and the volume which it occupies.

Let v be the volume thus occupied by the body at zero absolute temperature. Next, let the body while maintaining the constant volume undergo a succession of increases of temperature dT in such a manner as to bring about some state determined by its initial volume v and by its final temperature T. As often happens, the application of these elementary transformations of one of the laws so fruitful of displacements of equilibrium leads to quite remarkable conclusions.

The law under consideration in this case states that each

transformation at constant volume with a positive variation dT of temperature will produce an increase of entropy, the product $dSdT$ being necessarily positive. From this it follows that the entropy S of a body taken in any state whatsoever determined by its volume and its temperature (v, T) is a positive quantity, except for the case of the zero absolute temperature, when this entropy becomes equal to zero. In each of the elementary transformations thus considered, the variation of energy dU is given by the classical formula

$$dU = TdS - pdv$$

and as $dv = 0$,

$$dU = TdS$$

Since, according to what has been stated above, dS is positive, so will be dU. Each elementary rise dT of temperature will produce an increase of energy, and as the body starts from temperature zero with an energy nil or positive, it will necessarily reach a temperature T and a volume v, i.e., any state whatsoever, with a positive energy.

These two important consequences of the fundamental principles of thermodynamics tend to throw a vivid light on the notions of *absolute magnitude of entropy and absolute magnitude of energy.* It has just been shown that the entropy and the energy of a body can never go below the value which they have at the initial stage, as selected and defined above. And that can only mean that both the entropy and the energy of a body are quantities perfectly determined, usually positive, never negative, which are to be measured from this initial stage.

Furthermore, there is nothing surprising in the conditions under which entropy and energy become zero. In fact, these conditions appear fairly rational. The body maintained at the limit temperature of zero absolute, no matter what pressure it may be under, can have no tendency to transmit heat to the ambient medium, which is at least at the same temperature: hence, it is entropy which cannot undergo any reduction and has to be considered as being zero. If, in addition to that, the body does not support any pressure, then it has no expansive force, though capacity for work. And if it can cede its energy neither in the form of heat nor in the form of work, its energy must also be considered as nil. (*Sur la valeur absolue de l'entropie et de l'énergie.* E. Ariès. *Comptes rendus des séances de l'Académie des Sciences*, vol. 164, no. 20, May 14, 1917, pp. 774-776, *t*)

A Determination of the Heat of Vaporization of Water at 100 Deg. Cent. and One Atmosphere Pressure in Terms of the Mean Calorie, T. Carlton-Sutton

An article describing how the value of the latent heat of vaporization of water at 100 deg. cent. and one atmosphere pressure was measured directly in terms of the mean calorie by using a steam calorimeter that may be regarded as a development of Joly's classical apparatus. It is claimed that a high degree of accuracy has been attained on account of

1 An ice-bath that remains steady for one or two hours
2 A shielding device, by means of which a damp body can be left hanging in a steam chamber without loss or gain in weight: and
3 A determination of the effect of the dampness of the steam.

The temperature of a bulb of thermal capacity K is raised from the freezing point θ to the boiling point Θ by surrounding it with steam, a mass m of steam being condensed on the bulb, where

$$K(\Theta - \theta) = mL.$$

The bulb was then filled with water (of mass M) and the process repeated, a mass m' of steam being condensed, where, omitting small corrections,

$$(K - Ms)(\Theta - \theta) = m'L$$

whence

$$L = \frac{Ms}{m' - m}(\Theta - \theta) .$$

i.e., the heat of vaporization is measurable in appropriate calories $(s = 1)$ in terms of a temperature difference and the ratio of the masses M and $(m' - m)$.

The author then proceeds to describe the apparatus used and details of the method of experimentation and the necessary corrections applied.

The following results have been obtained: Determination with first bulb, 538.89 mean calories; with second bulb, 538.86 mean calories. These determinations are independent in the sense that they have been made with different bulbs and under different conditions of steam supply, and that any one measurement is used in one series only.

The values may be expected to agree to within seven or eight units in the fifth figure, a degree of accuracy that is confirmed by the experimental figures (see Tables).

The conclusion is, therefore, that the value 538.88 mean calories for the heat of vaporization of water at 100 deg. cent. and one atmosphere pressure is correct to the fourth significant figure for the samples of steam used; and in consideration of the results of Section E IX, it is held that the dampness of these samples has not affected the result to the extent of one part in 5000. (*Proceedings of the Royal Society*, Series A, vol. 93, no. A 649, pp. 155-176, 3 figs., *eA*)

Prizes for Research on Hardness of Metals

The Institution of Mechanical Engineers (Great Britain) has announced that Sir Robert A. Hadfield has placed in its hands the sum of £200, which, with any income thereon, may be awarded at the discretion of the Council of the Institution as a prize or prizes for the description of a new and accurate method of determining the hardness of metals, especially of metals of a high degree of hardness.

The ordinary tests of hardness such as are described in the report of the Hardness Test Research Committee (*Proceedings of the Institution of Mechanical Engineers*, 1916, pp. 677-778) fail to some extent when the hardness of the material exceeds about 600 to 800 Brinell. What is desired is a description of a research for, or an investigation of, some method of accurately determining hardness suitable for application in metallurgical work in cases where present methods partially fail.

The Council of the Institution will consider annually all communications received, but in January 1922 the offer of prizes will be withdrawn. Communications should be addressed to the Secretary, The Institution of Mechanical Engineers, 11 Great George St., Westminster, London, S.W.1, and marked "Method of Determining Hardness," and should reach him at least one month before the first of January in any year.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

Etude Experimentale du Réfroidissement de Divers Métaux par Immersion Dans L'Eau, M.M. Garvin and Portevin. Comptes Rendus Hebdomadaires des Séances de L'Académie des Sciences, tome 164, no. 20, May 14, 1917, pp. 783-786.
Cooling of metals by immersion in water.

Results of Tests of Sand-Cast Metals and Alloys. The Foundry, vol. 45, no, 299, July 1917, pp. 271-272, 2 figs.

Properties and Structure of Nickel Steel, S. W. Parker. The Iron Age, vol. 100, no. 2, July 12, 1917, pp. 67-69, illustrated.

Magnetic Analysis of Steel Products, Dr. Charles W. Burrows. The Iron Age, vol. 100, no. 2, July 12, 1917, pp. 74-78, 4 figs.

The Metallurgy of Ferrochromium, Robert J. Anderson. The Iron Trade Review, vol. 61, no. 2, July 12, 1917, pp. 75-78, 3 figs., 3 tables.

FORGINGS

Heat Treatment of Drop Forgings, Particular Attention to Automobile Parts—Methods of Determining Temperature of Steel During Heat Treatment—Checking Stock Distribution by Scleroscope Test—Rate of Heating, W. C. Peterson. The American Drop Forger, vol. 3, no. 6, June 1917, pp. 185-187.

FUEL AND FIRING

Powdered Coal. Railway Age Gazette, vol. 62, no. 24, June 15, 1917, pp. 1230-1232.

Motor Gasoline Properties, Laboratory Methods of Testing, and Practical Specifications, E. W. Dean. Bureau of Mines Technical Paper 166, Petroleum Technology 39, 27 pp., 1 fig., 1 table.

The Fuel Situation as Affected by the War, Railway Age Gazette, vol. 62, no. 25, June 22, 1917, pp. 1295-1298, 2 figs.

Les Remplacants de L'Essence, Experiences Suisses Alcool et Essence.. La Pratique Automobile, 13 annee, no. 249, pp. 5290-5292, 2 figs.
Gasoline substitutes.

Combination Coal and Gas Firing, Alex W. Morgan. Electrical World, vol. 70, no. 2, July 14, 1917, pp. 52-54, 5 figs.

HYDRAULICS

Flow Through Sharp-Edged Notches or Weirs, E. W. Doelber and F. H. Rayfield. The Cornell Civil Engineer, vol. 25, no. 8, May 1917, pp. 389-397, 7 figs.

The Friction of Water in Iron Pipes and Elbows, F. E. Giesecke. Journal of the American Society of Heating and Ventilating Engineers, vol. 23, no. 4, July 1917, pp. 587-594, 6 figs.

INTERNAL-COMBUSTION ENGINEERING

La tuyauterie d'échappement dans le moteur d'automobile, Henry W. Haegler. La Pratique Automobile, 13 annee, no. 239, January 15, 1917, pp. 1530-1530, 10 figs.
Exhaust piping in automobile engines.

Factors in Aviation Engine Design, Louis Coatalen. Pt. 1, The Automobile, vol. 36, no. 24, June 14, 1917, pp. 1129-1130. (To be continued).

Six Years' Development of the Werkspoor Marine Diesel Engine, Thomas Orchard Lisle. The Shipbuilder, vol. 16, no. 82, June 1917, pp. 313-317, 4 figs.

†The Sunbeam-Coatelen Aircraft Engines. The Auto, vol. 22, no. 23, June 8, 1917, pp. 405-406, 4 figs.

Heavy Oil Engine Facts and Fallacies, Reginald W. Crowly. The Automobile, vol. 36, no. 26, June 28, 1917, pp. 1212-1216, 7 figs.

Raising the Mean Effective Pressure, P. M. Heldt. The Automobile, vol. 36, no. 26, June 28, 1917, pp. 1237-1238.

Duesenberg Motor for Training Planes. The Automobile, vol. 37, no. 1, July 5, 1917, pp. 10-12, 5 figs.

Frontenac Aluminum Engine. The Automobile and Automotive Industries, vol. 37, no. 2, July 12, 1917, p. 57.

MACHINE PARTS

Ball Bearing for Electric Motors, H. N. Trumbull. Electrical Review and Western Electrician, vol 70, no. 25, June 23, 1917, pp. 1054-1057, 12 figs.

The Production of Screwed Elements, Trevor Rapson. The Automobile Engineer, vol. 7, no. 103, pp. 161-164, 14 figs.

Factory Transportation, Edward Hammond. Machinery, vol. 23, no. 11, July 1917, pp. 941-958, 54 figs.

MACHINE SHOP

Metal Extrusion, F. G. Schranz. Machinery, vol. 23, no. 11, July 1917, p. 959, 2 figs.

Gaging Systems for Screws and Taps. Machinery, vol. 23, no. 11, July 1917, pp. 967-968, 9 figs.

Evolution and Revolution in Machine Shop Practice, J. H. Rodgers. Canadian Machinery and Manufacturing News, June 28, 1917, pp. 677-682, 11 figs.

MACHINE TOOLS

Economy in Hacksaw Blades, Frank E. Merriam. Page's Engineering Weekly, vol. 30, no. 665, June 8, 1917, pp. 278-279, 281.

Efficiency of Forward and Reverse Drives, John S. Myers. Machinery, vol. 23, no. 11. July 1917, pp. 983-988, 9 figs.

Canada's Machine-Tool Industry in Retrospect. Canadian Machinery and Manufacturing News, June 28, 1917, pp. 683-693.

MARINE ENGINEERING

Le "Milazzo," Navire Charbonnier et Petrolier muni d'appareils spéciaux de déchargement. Le Génie Civil, tome 70, no. 25, June 23, 1917, pp. 397-399, 4 figs.
Coal- and oil-carrying ship *Milazzo*, with its special unloading apparatus.

How Wooden Ships Are Built, H. Cole Estep. Pt. 2, The Marine Review, vol. 47, no. 7, July 1917, pp. 231-237, 257. Illustrated. (concluded).

MECHANICS

Effect of Countershaft Speed Ratio on Power and Torque, A. Lewis Jenkins. American Machinist, vol. 47, no. 2, July 12, 1917, pp. 49-53, 3 figs., 3 tables.

The Specification of Stress, R. F. Gwyther. Memoirs and Proceedings of the Manchester Literary and Philosophical Society, 1915-1916, vol. 60, pt. 3, no. 14, pp. 1-5.

MEASUREMENTS

Temperature Measurements in Bessemer and Open-Hearth Practice, George K. Burgess. Technologic Papers of the Bureau of Standards, no. 91, 29 pp., 10 tables.

A Vibration Type Tension Meter. Flight, no 442 (no. 24, vol. 9), June 14, 1917, p. 583, 1 fig.

MUNITIONS

Testing Springs for Military Rifles, S. N. Bacon. Machinery, vol. 23, no. 11, July 1917, pp. 969-971, 5 figs.

POWER GENERATION AND TRANSMISSION

Cotton Rope for Power Transmission, J. Melville Alison. Proceedings of the Engineers' Society of Western Pennsylvania, vol. 33, no. 5, June 1917, pp. 271-303, 15 figs.

Power House Economics, V. T. Kropidlowski. Railway Mechanical Engineer, vol. 91, no. 7, July 1917, pp. 373-375, 4 figs.

RAILROAD ENGINEERING

†Analysis of the Axle Generator Belt Problem. Railway Electrical Engineer, vol. 8, no. 6, June 1917, pp. 149-151.

A Departure in Design of Export Coal Piers. Railway Age Gazette, vol. 62, no. 24, June 15, 1917, pp. 1226-1230, illustrated.

†Pennsylvania Locomotive of the Decapod Type. Railway Age Gazette, vol. 62, no. 24, June 15, 1917, pp. 1241-1243, 4 figs.

†Decapod Locomotive for the Pennsylvania R. R. Railway Review, vol. 60, no. 25, June 23, 1917, pp. 875-878, 15 figs.

†New Electric Locomotive, Pennsylvania R.R. Railway Review, vol. 60, no. 25, June 23, 1917, pp. 870-873, 8 figs.

Small Locomotives Used at the Front. Railway Age Gazette, vol. 62, no. 25, June 22, 1917, pp. 1383-1386, 7 figs.

Quick Repairs to a Heavy Locomotive. Railway Age Gazette, vol. 62, no. 25, June 22, 1917, pp. 1370-1373, 6 figs.

†Tests of Corrugated Culvert Pipe under a Sand Bed, George L. Fowler. The Railway Gazette, vol. 26, no. 24, June 15, 1917, pp. 687-691, illustrated.

Betrachtungen über die störenden Nebenbewegungen der Eisenbahn-Fahrzeuge mit besonderer Berücksichtigung des Einflusses der Radreifen-Konizität, U. R. Ruegger. Schweizerische Bauzeitung, band 69, no. 24, June 16, 1917, pp. 271-276, illustrated.
Disturbances in the moving of railroad cars due to side motions.

SCRAP METAL

The Ronay Metal Briquetting Process, A. L. Stillman. Automotive Engineering, vol. 2, no. 3, March 1917, pp. 77-79, 5 figs.

Reclaiming and Reusing the Factory Scrap, Joseph H. Gallon. Automotive Engineering, vol. 2, no. 4, April 1917, pp. 113-116, 2 figs.

The Briquetting of Metal Swarf. No. 3. The Engineer, vol. 123, no. 3208, June 22, 1917, pp. 557-588, figs. 5-6.

Ny Metod för Ekonomiskt Tillgodogörande af Metallaffall. Teknisk Tidskrift Mekanik, 47 arg., häft 6, pp. 53-55, 6 figs.
New method for economic handling of metal chips.

STEAM ENGINEERING

Condensing [illegible] Lots Road Power Station. Engineering, vol. 103, no. 2683, June 1, 1917, pp. 516-518, figs. 38-46. (to be continued).

Manchester Steam Users' Association. Engineering, vol. 103, no. 2683, June 1, 1917, p. 520.

Exhaust Heads. Practical Engineer, vol. 21, no. 13, July 1, 1917, pp. 534-535, 6 figs.

The "Howden" Sectional Type, Water-Tube Steam Boiler. Marine Engineering of Canada, vol. 7, no. 6, June 1917, pp. 127-130, 11 figs.

The Development of the Water Tube Boiler, W. F. Schaphorst. Steam, vol. 20, no. 1, July 1917, pp. 3-5. (to be continued).

Use of Thermometers to Increase Boiler Efficiency, H. A. Cozzens, Jr. Practical Engineer, vol. 21, no. 14, July 15, 1917, pp. 583-584.

THERMODYNAMICS

†Sur la valeur absolue de l'entropie et de l'énergie, M. E. Ariès. Comptes Rendus Hebdomadaires des Séances de L'Académie des Sciences, tome 164, no. 20, May 14, 1917, pp. 774-776.
Absolute value of entropy and energy.

Intorno ad Alcuni Modi di Calcolare L'Esperienza di Clement e Desormes e di dedurne l'equivalente meccanico della caloria, G. Guglielmo. Il Nuovo Cimento, Anno 62, serie 6, vol. 12, 2 Sem., fasc. 11, November 1916, pp. 195-212.
Concerning some methods of computing the experimental data of Clement and Desormes, and of deducing from them the value of the mechanical equivalent of heat.

WELDING

Welded Containers, Charles Hollup. Refrigerating World, vol. 52, no. 6, June 1917, pp. 25-27, 14 figs.

Welds—The Weaknesses and Merits of Their Structure, P. A. E. Armstrong. Power, vol. 45, no. 26, June 26, 1917, pp. 856-860, 5 figs.

Assisting Shrinkage in Autogenous Welding by Mechanical Means. The Railway Gazette, vol. 26, no. 25, June 22, 1917, p. 717, 1 fig.

VARIA

Balancing Machine Improved. The Automobile, vol. 36, no. 24, June 14, 1917, pp. 1132-1133, 3 figs.

The Primary Volatile Products of the Carbonization of Coal, Guy B. Taylor and Horace C. Porter. Bureau of Mines, Technical Paper 140, 55 pp., 25 figs.

The New Engineering Laboratories. The Technology Review, vol. 19, no. 1, January 1917, pp. 1-8.

The National Physical Laboratory in 1916-1917. Engineering, vol. 103, no. 2686, June 22, 1917, pp. 598-599, 1 fig. (to be continued).

National Physical Laboratory Report for the Year 1916-17. Flight, no. 443 (no. 25, vol. 9), June 21, 1917, pp. 611-612.

Workshop Training of Apprentices in the Light of Recent Developments, Neil J. Maclean. Engineering, vol. 103, no. 2686, June 22, 1917, pp. 583-584.

Design of Concrete Tanks, Ernest McCullough. Illinois Society of Engineers, Thirty-second Annual Report, 1917, pp. 40-44.

L'Enseignement Technique Supérieur, Discussion sur la formation des ingénieurs à la Société des Ingénieurs Civils de France. Le Génie Civil, tome 70, no. 25, June 23, 1917, pp. 399-404.
Higher technical education in France (a discussion).

Glasses for Protecting the Eyes from Injurious Radiations, W. W. Coblentz and W. B. Emerson. Technologic Papers of the Bureau of Standards, no. 93, 14 pages.

Reducing Cost of Ingot Molds. The Iron Trade Review, vol. 60, no. 16, April 19, 1917, pp. 880-884, 12 figs.

Hyperbolic Analysis for Engineering Problems, W. D. Peaslee. Journal of Electricity, vol. 39, no. 1, July 1, 1917, pp. 8-10.

CHARTS

Charts for Calculating Engine or Turbine Efficiency, Fig. 1, Condenser Water Rate Chart; Fig. 2, Efficiency Chart for Turbines and Engines. The Practical Engineer, vol. 21, no. 12, June 15, 1917, pp. 497-498.

Chart for Adjusting Levers of Track Scales. Scale Journal, vol. 3, no. 9, June 1917, p. 11.

Comparative Logarithmic Curves for V-Notched Weirs, Flow through Sharp-Edged V-Notches or Weirs, E. W. Doebler and F. H. Rayfield. The Cornell Civil Engineer, vol. 25, no. 8, May 1917, p. 397.

Balanced-Rudder Stocks, Peter Doig. The Shipbuilder, vol. 16, no. 82, June 1917, p. 310.

Chart for Determining Inertia Force. The Automobile, vol. 36, no. 26, June 28, 1917, pp. 1211.

Chart to Determine Relative Cost of Coal and Oil Fuel, R. L. Wales. Engineering and Mining Journal, vol. 103, no. 26, June 30, 1917, pp. 1147.

The Synthetic Air Chart, Dr. E. V. Hill. Journal of the American Society of Heating and Ventilating Engineers, vol. 23, no. 4, July 1917, p. 494.

Modification of the Synthetic Air Chart Introducing Air Motion Curves, Dr. E. V. Hill. Journal of the American Society of Heating and Ventilating Engineers, vol. 23, no. 4, July 1917, p. 496.

Chart Showing Power Required to Move Air Through the Channels, Arthur K. Ohmes. Journal of the American Society of Heating and Ventilating Engineers, vol. 23, no. 4, July 1917, p. 581.

LIBRARY NOTES

From the Libraries of the Four Founder Societies and the United Engineering Society, in the Engineering Societies Building, New York City

A. S. M. E. Accessions

ENGINEERING ECONOMICS. By J. A. L. Waddell. *Lawrence, Kansas, 1917.* Gift of A.S.M.E.

GREENFIELD TAP AND DIE CORPORATION. Manual containing instructions and information issued to employees *Greenfield, n.d.* Gift of Greenfield Tap and Die Corporation.

HOW TO PUT THE CRIPPLED SOLDIER ON THE PAYROLL. By Frank B. and Lillian M. Gilbreth. Reprinted from the May 1917 number of the Trained Nurse and Hospital Review. Gift of Author.

INDUSTRIAL DEVELOPMENT IN KANSAS. By P. F. Walker. Gift of A.S.M.E.

INTERNATIONAL HIGH COMMISSION. An appendix to the report of the United States section of the International High Commission on the first general meeting, held at Buenos Aires, April 3-12, 1916. U. S. Senate, 64th Congress, 2d session. Doc. No. 739. *Washington, 1917.* Gift of A.S.M.E.

NEW ENGLAND ASSOCIATION OF GAS ENGINEERS. Proceedings, 1909-10, 1915-16. *Boston, 1909, 1915.* Gift of Association.

OUTLINE OF THE METALLURGY OF IRON AND STEEL. Blue print. By Frank E. Sanborn. *1917.* Gift of author.

POLYTECHNIC ENGINEER. Vol. XVII, 1917. *Brooklyn, 1917.* Gift of Brooklyn Polytechnic Institute.

RICE'S GUIDEBOOK ON WATER TREATING FOR INDUSTRIAL PURPOSES. By Cyrus W. Rice. *Philadelphia, n.d.* Gift of author.

SCIENTIFIC MANAGEMENT PRACTICALLY APPLIED. Address by Fred J. Miller before the Cleveland Chamber of Commerce, Dec. 12, 1916. Gift of F. J. Miller.

THEORETICAL DEPRECIATION. Presented for the consideration of the Public Service Commission for the First District, State of New York, by the Consolidated Gas Company of New York. Gift of A.S.M.E.

U. E. S. Accessions

AMERICAN GAS INSTITUTE. Proceedings. Vol. XI, pt. 1-2. *New York, 1917.* Purchase.

BOSTON PUBLIC LIBRARY. Annual Report of the Trustees, 1916-17 *Boston, 1917.* Purchase.

CARNEGIE LIBRARY OF PITTSBURGH. Annual Reports to the Board of Trustees. 21st. *Pittsburgh, 1917.* Purchased.

CEMENT WORLD. Vols. 1-2. *Chicago, 1907-1908.* Purchased.

COMITE CENTRAL DES HOUILLERES DE FRANCE. Codes Miniers—Russie. *Paris, 1895.* Purchase.

COMMERCIAL FERTILIZER. Year Book, 1917. *Atlanta, 1917.* Purchase.

ELECTRIC SWITCH AND CONTROLLING GEAR. By Charles C. Garrard. *London, 1916.* Purchase.

ENGINEERING ASSOCIATION OF NEW SOUTH WALES. Vol. XXXI. *Sydney, 1916.* Purchase.

THE EXTENSION OF MUNICIPAL ACTIVITIES and its effect on municipal expenditures, including a review of the budgets of New York City since consolidation, 1898-1917. Lecture by W. A. Prendergast. Delivered at the College of the City of New York, Feb. 14, 1917. Gift of New York City Dept. of Finances.

GEOLOGY OF A PORTION OF THE FLATHEAD COAL AREA, BRITISH COLUMBIA. Canada. Mines Department. Memoir 87. *Ottawa, 1916.* Purchase.

HYPERACOUSTICS. Division I—Simultaneous tonality. By John L. Dunk. *London-N. Y., 1916.* Purchase.

LOS ANGELES BOARD OF HARBOR COMMISSIONERS. Port of Los Angeles, Jan. 1, 1917. Gift of Board of Harbor Commissioners.

MANUFACTURE OF SULPHURIC ACID AND ALKALI WITH THE COLLATERAL BRANCHES. Ed. 1. Supplement to Vol. 1. Sulphuric and Nitric Acid. By George Lunge. *London, 1917.* Purchase.

MILWAUKEE (WIS.) CITY PLANNING FOR MILWAUKEE. What it means and why it must be secured. *Milwaukee, 1916.* Gift of Milwaukee Real Estate Association.

NEW INTERNATIONAL YEAR BOOK, 1916. *New York, 1917.* Purchase.

NEW YORK STATE BRIDGE AND TUNNEL COMMISSION. Report, 7th. *Albany, 1917.* Gift of Commission.

NEW YORK (STATE) PUBLIC SERVICE COMMISSION FOR THE FIRST DISTRICT. Report, 1915. Vols. I-II. *Albany, 1916.* Purchase.

OIL AND PETROLEUM MANUAL, 1917. By Walter H. Skinner. *London, 1917.* Purchase.

ROYAL SOCIETY OF VICTORIA. Transactions. Vol. VI, 1914. *Melbourne, 1914.* Purchase.

SPECIAL COLLECTIONS IN LIBRARIES IN THE UNITED STATES. By W. D. Johnston and Isadore G. Mudge. U. S. Bureau of Education, Bulletin no. 23. *Washington, 1912.* Purchase.

THE STORY OF BETHLEHEM STEEL. By Arundel Cotter. The Moody Magazine and Book Co., *New York, 1916.* Cloth, 5 x 7½ in., 65 pp., 8 illustrations. $0.75. Gift of the publisher.

TEXT BOOK ON MOTOR CAR ENGINEERING. Vol. III—Design. By A. G. Clark. *London, 1917.* Purchase.

TOPICOS TECNICOS. By Octavio A. Acevedo. *Santo Domingo, R. D., 1917.* Gift of author.

TREATISE ON QUANTITATIVE INORGANIC ANALYSIS. J. W. Mellor. *London, 1913.* Purchase.

UNDERWRITERS' LABORATORIES. List of Inspected Mechanical Appliances, July 1916. Purchase.

—— —— List of Inspected Electrical Appliances, April 1917. Purchase.

U. S. DEPARTMENT OF COMMERCE, Bureau of Foreign and Domestic Commerce. Artificial Dyestuffs used in the United States. Special Agents Series, no. 121. *Washington, 1916.*

—— —— Danish West Indies, their resources and commercial importance. Special Agents Series, no. 129. *Washington, 1917.*

PERSONALS

***I**N these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by August 16 in order to appear in the September issue.*

CHANGES OF POSITION

Paul Fenton, formerly instructor of machine design at Cornell University, Ithaca, N. Y., has accepted a position as engineer with the Hughes Tool Company, Houston, Tex.

Emile G. Jegar, formerly assistant chief engineer of The Arlington Company, Arlington, N. J., has become affiliated with the Du Pont Fabrikoid Company, Newburgh, N. Y.

Olaf T. Ansson, mechanical engineer with The Iola Portland Cement Company, Iola, Kan., has become associated with the Cuban Portland Cement Company, Mariel, Cuba.

Howard A. Gillan, formerly assistant engineer with the Union Pacific System, New York, has assumed the duties of purchasing engineer of the Eastman Kodak Company, Rochester, N. Y.

Howard G. Wright, superintendent of construction, Anaconda Copper Mining Company, Anaconda, Mont., is at present connected with the U. S. Smelting Company, Salt Lake City, Utah.

Walter Grothe has severed his connection with the National Carbon Company, Fremont, O., and has taken up the duties of engineer for the C. L. Best Gas Traction Company of San Leandro, Cal.

Andrew Westwater, formerly with the Columbia River Ship Building Corporation, Portland, Ore., has been appointed chief engineer of the G. M. Standifer Construction Corporation of the same city.

C. R. Cady, until recently industrial engineer with Smith, Hinchman and Grylls, Detroit, Mich., has assumed the duties of manager of the wheel department of The Clark Equipment Company, Buchanan, Mich.

Clarence Fichter has severed his relations with the Chatfield Manufacturing Company, Cincinnati, O., and has accepted a position as combustion engineer with Day and Zimmermann, of Philadelphia, Pa.

John W. Woodcock has severed his connection with the Crane Company, of Bridgeport, Conn., and has accepted the position of mechanical superintendent of the Pratt and Cady Company, Hartford, Conn.

James L. Kirsch, formerly engineer in the estimating department of Struthers-Wells Company, Warren, Pa., is now associated with the Adamson Machine Company, Akron, O., in the capacity of superintendent.

Henry A. Stringfellow has resigned his position of mechanical engineer with the Sedgwick Machine Works, New York, and has accepted a position as designer with the Epping-Carpenter Pump Company, of Pittsburgh, Pa.

Robert R. Keith, for the past five years in charge of the Sheffield Plant of the Fairbanks-Morse Company, Three Rivers, Mich., has recently accepted the position of plant manager of The Holt Manufacturing Company, Peoria, Ill.

Richard M. James, rate setter with the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., has entered the employ of the Boonton Rubber Manufacturing Company, Boonton, N. J., as foreman of the finishing department.

Walter S. Giele, formerly general superintendent of the plants of the Harrison Safety Boiler Works, Philadelphia, Pa., is now connected with the Lebanon Gear and Machine Works, Lebanon, Pa., as vice-president and general manager.

Ronald V. Billington has become associated with the Interstate Commerce Commission, Kansas City, Mo., as junior engineer. He was, until recently, connected with the engineering department of the Great Western Sugar Company, Lovell, Wyo.

Axtell A. Lloyd has left the employ of the American Ammunition Company, of New York, and has become affiliated with the Greenfield Tap and Die Corporation, in the capacity of designer, with headquarters at their Springfield, Mass., arsenal.

Edwin P. Davis, for the past two years in the engineering department of the Remington Arms and Ammunition Company, Bridgeport, Conn., has resigned to accept the position of superintendent of the Modern Manufacturing Company of the same city.

Robert W. Sweeny, chief draftsman of the car department of the Chicago, St. Paul, Minneapolis and Omaha Railway, Hudson, Wis., has become affiliated with the Minnesota Manufacturers' Association, North St. Paul, Minn., in the capacity of chief engineer.

John B. Price has entered the employ of The Mechanical Appliance Company, of Milwaukee, Wis., with temporary headquarters at Chicago, Ill. He was, until recently, connected with the Peerless Electric Company, Warren, O., as assistant superintendent.

Siegfried Rosenzweig, formerly mechanical engineer with the Erie City Iron Works, and at the present time consulting engineer of the steam-engine department of the York Manufacturing Company, York, Pa., has also joined the American Spray Company, New York, in a similar capacity.

George P. Rettig, mechanical engineer with the Cincinnati Motor Syndicate, Cincinnati, O., has become associated with the office of the army inspector of the Curtiss-Elmwood plant at Buffalo, N. Y. Mr. Rettig is connected with the U. S. Signal Service at large, as inspector of airplanes and airplane-engines.

ANNOUNCEMENTS

James H. Herron has been elected president of The Cleveland Engineering Society.

Charles C. Lynde, editor of *The Blast Furnace and Steel Plant*, joined the Engineers' Officers Reserve Camp at Fort Oglethorpe, Ga., on May 21.

Leroy T. Byron has enlisted in the U. S. Naval Reserve Forces as chief petty officer, and is on duty at the Brooklyn Navy Yard, Brooklyn, N. Y.

Amasa M. Holcombe has been assigned to active duty in the small arms division of the Ordnance Department, United States Army, Washington, D. C.

Lieut. A. Langstaff Johnston, Jr., has been called to active duty at the Newport News Shipbuilding and Drydock Company, Newport News, Va., and has temporarily closed his office in Richmond, Va.

Ambrose Swasey, Past-President, Am.Soc.M.E., was elected president of the Cleveland Young Men's Christian Association, at the annual election on June 1. He has been very active in the association, and has been its first vice-president for several years.

Captain Elmer K. Hiles has been called into active service of the Fifth Regiment, Engineers' Reserve Corps, and has reported for duty. Captain Hiles is secretary of the Engineers' Society of Western Pennsylvania, and began training for the service last summer at Plattsburg.

John P. Flippen, formerly chief engineer of the C. H. Wheeler Manufacturing Company, Philadelphia, Pa., is now district manager of that company's interests in Western Pennsylvania, Ohio and West Virginia, with offices in Cleveland and Pittsburgh. Mr. Flippen is operating in conjunction with the Baker Dunbar Allen Company, contracting engineers.

It was incorrectly stated in the July Journal that Gail H. Browne left the employ of Ford, Bacon and Davis. Mr. Browne has been transferred from the New Orleans office of the company to their New York office, and is still employed by them as resident engineer on an increased power project for the Lehigh Valley Transit Company at Allentown, Pa.

THE NEW BOOKS

ALL books received by The Journal will be listed under this heading, generally accompanied by brief descriptive notes. Works of special importance to mechanical engineers will be commented on at length by members and others peculiarly qualified by reason of their experience and training.

Franco-American Trade. Report to the American Manufacturers' Export Association by the American Industrial Commission to France. The American Manufacturers' Export Association, 160 Broadway, New York, 1917. Boards, 8 x 10¾ in., 256 pp., 51 illustrations and 10 folding maps

The American Industrial Commission to France, organized and sent by the American Manufacturers' Export Association in August 1916 (see THE JOURNAL, September 1916, p. 735), has recorded in a handsome volume, just issued, the results of its comprehensive study of the means whereby American resources may best be made available for the reconstruction of the devastated regions, and Franco-American trade relations may otherwise be furthered.

The Commission, whose personnel included Messrs. W. W. Nichols (Chairman), Laurence V. Benét and J. E. Sagne of this Society, was composed of twelve members representative of a wide range of interests, and in the forty-odd days spent in the chief industrial centers and ports of the sister republic managed to accumulate the wonderful fund of information which is here set forth with an abundance of illustrations and maps.

The work consists of twenty-five chapters and an appendix, and among the many topics treated are those of trade and tariff, industry and plant construction; industrial and agricultural machinery, labor, syndicates and coöperative socities; chambers and courts of commerce, seaports and shipping, transportation; hydroelectric power; chemical industry; alcohol, social welfare, city planning; education, the devastated regions and their rehabilitation; Belgian reconstruction, etc. Manifestly it has been impossible to give more than a very general outline of any one subject, but it is the belief of the Commission that the facts cited and opinions expressed will throw light not only on present conditions, but on some of the probable developments that may be anticipated as a result of the war. A suggestive bibliography, as well as reports and recommendations of the American Chamber of Commerce in Paris, made at the request of the Commission, are included.

A Discussion of the Principles and Practice Underlying Charges for Water, Gas, Electricity, Communication and Transportation Services. By Harry Barker. McGraw-Hill Book Co., Inc., New York, 1917. Cloth, 6 x 9 in., 387 pp. $4.

The author's aim has been to present, concisely and impartially, and as far as possible in non-technical language, the diverse phases of rate-making for public utilities, including a comprehensive discussion of (1) such corporation and municipal activities as affect service and rates; (2) the trend of public opinion and court and commission decisions; and (3) the most important engineering and economic problems involved, with the hope that it will prove of service to lawyers and legislators, to editorial writers of the daily press, to students of municipal affairs, and to the general public. Contents: Development of Utility Regulation; Utility Privileges and Obligations; Rights of the Public; Product and Service Companies; Some Definitions of Rates and Services; Various Bases for Rates; Details of the Cost-of-Service Study of Rates; Test for Fixed and Operating Charges; Fair Value of a Utility Property; Valuation as an Engineering Task; Appraisal of Land and Water Rights; Reasonable Return, Interest, Compensation for Risk and Attention, Extra Profits; Depreciation as it Affects Utility Rates; Miscellaneous Problems Indirectly Related to Rate-Making; Problems of Railway Rates; Problems of Express Transportation Rates; Rate Problems of Street and Interurban Railway Transportation; Problems of Water Rates; Rate Problems of Gas Utilities; Rate Problems of Electricity Supply Works; Problems of Telephone Rate-Making; Appendices (4).

Modern Underpinning: Development, Methods and Typical Examples. By Lazarus White and Edmund A. Prentis, Jr. John Wiley & Sons, Inc., New York, 1917. Cloth, 6 x 9 in., 94 pp., 48 illustrations. $1.50.

Exhibits by means of photographs and drawings the essential steps in underpinning as illustrated by the methods used in subway construction in New York City. Only enough text to supplement the illustrations is included. Contents: General Aspects; Development of Underpinning and Methods; Shores, Needles, and Foundation Reinforcements; Specific Examples of Underpinning; Appendix.

Steam Piping. Its Economical Design and Correct Layout. By A. Langstaff Johnston, Jr. The Engineering Magazine Co., New York, 1916. Cloth, 5 x 7½ in., 62 pp., 7 illustrations, $2.

Consolidated and revised from a series of articles published in *The Engineering Magazine* in 1915. The factors governing the flow of steam in pipes are analyzed, and a group of curves is presented for use in solving the problems of practical installation and determining the most economical size of pipe to select for any given conditions. Contents: How to Find the Right Pipe Sizes; Special Conditions Affecting Low-Pressure Systems; and Savings Obtainable from Exhaust Steam.

Microscopic Examination of Steel. By Henry Fay. John Wiley & Sons, Inc., New York, 1917. Cloth, 6 x 9 in., 18 pp., 32 full-page plates. $1.25.

While originally issued by the Ordnance Department, U. S. A., and intended for the exclusive use of inspectors of ordnance material, this volume is now published for the use of others interested in the inspection of steel. It presents an outline of metallographic methods, illustrating typical examples. It is intended, not for use as a textbook, but particularly for those who are in need of some help in the interpretation of results.

Steam Power. By C. F. Hirshfeld and T. C. Ulbricht. John Wiley & Sons, Inc., New York, 1916. Cloth, 5¼ x 8 in., 420 pp., 232 figs. $2.

The authors have endeavored to collect in a comparatively small book such parts of the field of steam power as should be familiar to engineers whose work does not require that they be conversant with the more complicated thermodynamic prin-

ciples considered in advanced treatments, and the work is primarily intended for use as a textbook by students of civil engineering and in teaching power plant operators. Mathematical treatment of the subject has been eliminated to the greatest possible extent.

The Theory of Machines. By Robert W. Angus, B. A. Sc., Mem.Am. Soc.M.E. Second edition. McGraw-Hill Book Co., Inc., New York, 1917. Cloth, 6 x 9 in., 510 pp., 193 figs., $3.

This is a treatise on the principles of mechanism and the elementary mechanics of machines, for use in colleges. It deals with problems of fairly common occurrence, for which graphical solutions have been devised by the author. In the first part of the book a vector method of representing the relative motions of the different parts of a mechanism, called the "phorograph" method, is employed, which, it is stated, appeared in print for the first time in the previous edition. The second part, of much greater difficulty, is devoted to governors, speed fluctuations, flywheel weights, accelerations in machinery and their effects, balancing (new chapter), etc.

The Ventilation Hand Book: The Principles and Practice of Ventilation as Applied to Furnace Heating; Ducts, Flues and Dampers for Gravity Heating; Fans and Fan Work for Ventilation and Hot Blast Heating. By Charles L. Hubbard. Sheet Metal Publishing Co., New York, 1916. Cloth, 6 x 8 in., 218 pp., 137 figs. $2.

A series of questions, answers and descriptions, with illustrations arranged from a series of articles prepared for *Sheet Metal*. The author states that he has endeavored to keep all descriptions and mathematical work well within the understanding of the student and beginner.

Handbook of Casinghead Gas. By Henry P. Westcott. Metric Metal Works, Erie, Pa., 1916. Cloth, 5 x 8 in., 274 pp., 49 illustrations, $2.50.

Information on the processes used for extracting gasoline from natural gas, based on visits to many existing plants and a study of their reports. Contents: General Physical Properties of Casinghead Gas Wells; Construction of Pipe Lines; Measuring Casinghead Gas; Gasoline Plant, Compression Method; Gasoline Plant, Absorption Method; Transportation of Gasoline; Miscellaneous.

Steam Turbines: A Treatise Covering U. S. Naval Practice. By G. J. Meyers. The U. S. Naval Institute, Annapolis, Md., 1917. Cloth, 8 x 12 in., 246 pp., 202 figs. $4.50.

This book has been prepared to serve as an elementary treatise on steam turbines for the use of midshipmen at the U. S. Naval Academy, and deals mainly with types found in the U. S. Naval Service.

Practical Sheet Metal Duct Construction: A Treatise on the Construction and Erection of Heating and Ventilating Ducts. By William Neubecker. The Sheet Metal Publishing Co., New York, 1916. Cloth, 6 x 8 in., 194 pp., 217 figs. $2.

Illustrated descriptions of the various operations involved in the construction and erection of sheet-metal air ducts.

A Handbook for Cane-Sugar Manufacturers and Their Chemists. By Guilford L. Spencer. Fifth edition, enlarged. John Wiley & Sons, Inc., New York, 1916. Leather, 4 x 7 in., 529 pp., 83 figs. $3.50.

The book is divided into two parts, Manufacture of Cane Sugar and Sugar Analysis, and includes a chapter on sugar refining as practiced in the United States. The chemical section of the book, it is stated, has been revised to meet the conditions of the very large factories now in operation.

Central-Station Electric Service: Its Commercial Development and Economic Significance as Set Forth in the Public Addresses 1897-1914, of Samuel Insull. Edited, with an Introduction by William Eugene Kelly. Privately printed, Chicago, 1915. Cloth, 6 x 9 in., 195 pp., 105 figs.

A collection of forty speeches bearing on central-station electric service delivered by the author between 1897 and 1914. The editor states that these addresses are the work of one who has led the way to new conceptions of the economic functions of central-station electric service, and that much information of historical value, some of it never before published, is scattered through the book.

A Manual of Fire Prevention and Fire Protection for Hospitals. By Otto R. Eichel. John Wiley & Sons, Inc., New York, 1916. Cloth, 5 x 7½ in., 69 pp. $1.

An outline of the principles of fire prevention and protection, with indications for their application in institutions housing the sick, based on the personal observation and study of the author, who is Director of the Division of Sanitary Supervisors, New York State Department of Health.

Hendricks' Commercial Register of the United States for Buyers and Sellers. Twenty-fifth annual edition. S. E. Hendricks Co., Inc., New York, 1916. Cloth, 8 x 10 in., 1738 pp. $10.

An annual directory of producers, manufacturers, dealers and consumers connected with the architectural, contracting, electrical, engineering, hardware, iron, mechanical, mill, mining, quarrying, railroad, steel and kindred industries. Intended as a reference book for buyers.

Spon's Electrical Pocket-Book: A Reference Book of General Electrical Information, Formulae and Tables for Practical Engineers. By Walter H. Molesworth. Spon & Chamberlain, New York, 1916. Cloth, 4 x 7 in., 488 pp., 325 figs. $2.

It is stated in the preface that the author's aim has been to treat all of the subjects concisely and to avoid intricate mathematics. Full metric conversion tables are included.

Electric Traction: A Treatise on the Application of Electric Power to Tramways and Railways. By A. T. Dover. Whittaker & Co., New York and London, 1917. Cloth, 6 x 9 in., 667 pp., 523 illustrations. $5.50.

This work is designed for the use of engineers and advanced students. Representative examples of modern tramway and railway practice are included, but detailed accounts of electrification have been omitted and generating stations and transmission lines have not been considered. A number of worked-out examples are given in the text. Contents: Mechanics of Train Movement; Motors; Control; Auxiliary Apparatus; Rolling Stock; Detailed Study of Train Movement; Track and Overhead Construction; Distributing Systems and Sub-Stations; Bibliography on Electrification.

French Measures and English Equivalents. By John Brook. Spon & Chamberlain, New York, 1917. Cloth, 3 x 4 in., 80 pp. $0.40.

Gives the English equivalents (correct to six places) of the metric measures of length and weight and of the old French, Prussian, Austrian and Russian measures of length. Intended for engineers, manufacturers and workmen.

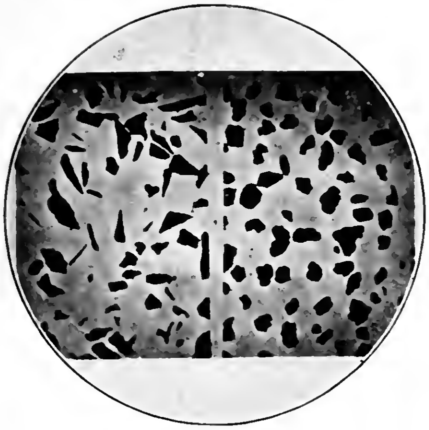

Fig. 1 Crystalline and Amorphous Natural Graphite

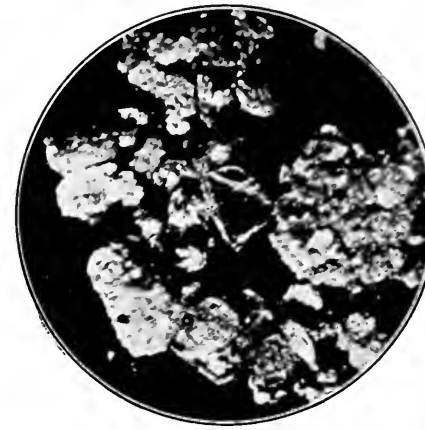

Fig. 3 Impurities in Micaceous Graphite (120 Diameters)

A STUDY OF GRAPHITE AND OF ITS COMPOUNDS FOR LUBRICATING PURPOSES

By CHRISTOPHER H. BIERBAUM,[1] BUFFALO, N. Y.

Member of the Society

MAN'S earliest knowledge of graphite dates back to the remotest antiquities, its application for useful purposes being shown in the prehistoric remains on continental Europe. Here it had been used not only as a coloring material in the early art of pottery making, but also mixed with clay for making refractory melting pots or crucibles.

The earliest written history of graphite seems rather indefinite, leaving considerable doubt in some instances as to whether graphite was actually referred to or some other mineral substance. This was due entirely to a lack of exact chemical knowledge, which resulted in confusing graphite with lead and molybdenite and gave rise to the terms—still modern—plumbago, black lead, *reisblei, crayon noir,* and the like.

The first positive and definite written accounts of graphite and its uses for refractory melting pots are given by Agricola (1494-1555). The next definite economic use of graphite of which we have written history is in the lead pencil, made as far back as the sixteenth century by placing a carefully shaped piece of natural graphite into a grooved wooden stick. It may never be known who first used graphite for lubrication in modern machinery, though bearing troubles in the modern sense could not have existed until after modern machinery existed. Statistics show that the number of users of graphite for lubricating purposes is increasing at an enormous rate, the consumption for this purpose for the latest year for which we have data, namely, 1913, being 30,000 tons.

Early in the writer's experience with bearings and lubricating problems, graphite proved an inviting subject. The results obtained, however, were so varied and at times so unsatisfactory that he was finally led to investigate broadly the entire subject of graphite for lubrication, which resulted in perfecting a process by means of which more than thirteen per cent of earthy materials have been eliminated from one of the best-known graphites on the market.

Graphite is one of the three allotropic forms of the chemical element carbon, amorphous carbon—say, the charcoal made of pure sugar—and the diamond being the other two. All three forms are subject to a large number and variety of impurities. It is the impurities of a graphite that largely determine its physical characteristics, and, strange as it may seem, graphite is a material whose impurities give it its designation.

The origin of graphite is twofold—natural and artificial. Artificial graphite is a by-product of the electric furnace in the production of silicon carbide, which is known in the trade as carborundum and crystolon. Natural graphite is derived from coal or early vegetable forms, and from bituminous sources. The gradual process in which Nature has produced graphite from the vegetation of the Carboniferous Age is distinctly seen in the successive steps in the development of the coal formations—peat, lignite, semi-bituminous, bituminous, semi-anthracite, anthracite, and finally graphite itself, having all the impurities corresponding to the admixture of earthy matter during the entire development. The natural graphite of vegetable origin is that generally known as natural amorphous graphite. This is usually a high grade of graphite, that is, the carbon is usually very completely graphitized and free from the high hydrocarbons, but has very decided drawbacks owing to its impurities, consisting mostly of earthy admixtures. The other class of natural graphite is that formed of asphaltic or bituminous matter. The best examples of this class are the Ceylon grades, many of which are known as crystalline or columnar—sometimes called fibrous graphites. In addition to earthy impurities, this graphite also contains some of the very highest orders of the hydrocarbon compounds. The affinity that hydrogen has for carbon is very strikingly shown in these graphite formations: the conversion of the carbon to graphite seems complete and the hydrogen is still held in combination, at least in part. In fact, one of the world's greatest diamond experts finds that the Brazilian

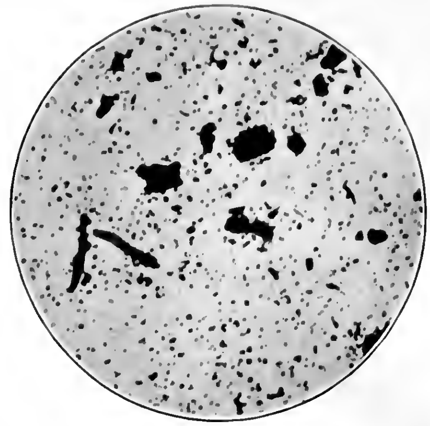

FIG. 6 ARTIFICIAL GRAPHITE SHOWING SILICON CARBIDE (120 DIAMETERS)

diamond still possesses a small percentage of hydrogen and that its specific luster is due to this impurity. To the latter class of natural graphites, those of bituminous origin, belong the micaceous graphites, those formations in which the flakes are made up of alternate layers of mica and graphite; and also those having sufficient micaceous material to impart to the graphite the crystallized structure corresponding to the different varieties of mica.

It will be observed that the usual classification is not adhered to—that the micaceous graphite is not included in the crystalline variety. The reasons for this classification are as follows:

1 Some of the very finest microscopic subdivisions of the coarsely laminated micaceous varieties appear to be amorphous

2 All varieties of the micaceous graphites when ground to ultramicroscopic fineness show transparent particles of mica

3 There is a clear dividing line between the micaceous and non-micaceous graphites of bituminous or non-organic origin.

The characteristic difference between two of the natural graphites, the amorphous and crystalline, is shown in Fig. 1. The right-hand side represents the amorphous graphite and the left side the crystalline. They are substantially of the same degree of purity, one—the amorphous—having more or less irregular rounded particles, while the other has sharp and angular particles. This holds true even though the particles are reduced to the minutest microscopic subdivisions. According to the foregoing classification the strictly crystalline graphites, not being suited for lubrication, are not given further consideration.

Fig. 2 shows a very beautiful specimen, a sliver or transverse section of the micaceous variety of graphite (magnified 200 diameters), in which are seen the alternating layers of mica and graphite, the mica being translucent or light colored and the graphite black or strictly opaque. This striated oblong particle shows a small portion broken off from the main body but still held by a filament of mica which has been bent, showing that the mica is of the flexible variety. This, together with the lines of fracture shown under the microscope, indicates that this particular mica is the variety known as muscovite, a comparatively tough and flexible variety. This specimen has rather coarse laminations, corresponding to the largest flake formation, the layers of mica approaching a thickness of 0.0001 in. Anyone can appreciate that graphite having this amount of mica as an impurity is undesirable in bearings. To illustrate, if one of these particles should become located between an engine shaft and its babbitt bearing over night, the inevitable result would be "pockmarking."

Fig. 3, a photomicrograph, shows the impurities taken from one of the highest grades of micaceous or flake graphite procurable on the market. It shows a number of crystals of abrasive material and other particles composed of mica, clay, alumina, hornblende, and the like. A simple method of testing the abrasive properties of these impurities was resorted to: it consisted in placing a small soft-wood block on the

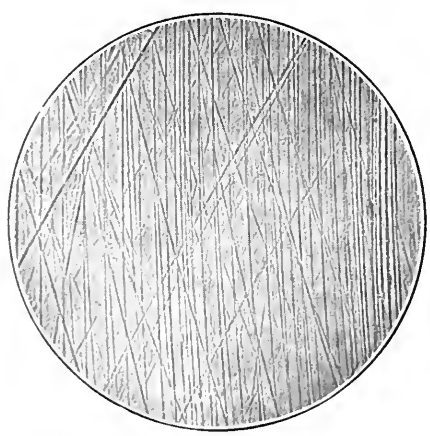

FIG. 8 ABRASIONS MADE BY SILICON CARBIDE (120 DIAMETERS)

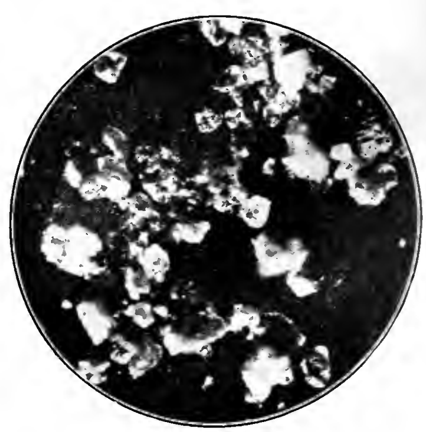

FIG. 9 IMPURITIES IN AIR-FLOATED GRAPHITE (120 DIAMETERS)

Fig 10 Abrasions Made by Impurities in Air-Floated Graphite (120 Diameters)

Fig. 11 Milled Bronze Surface (100 Diameters)

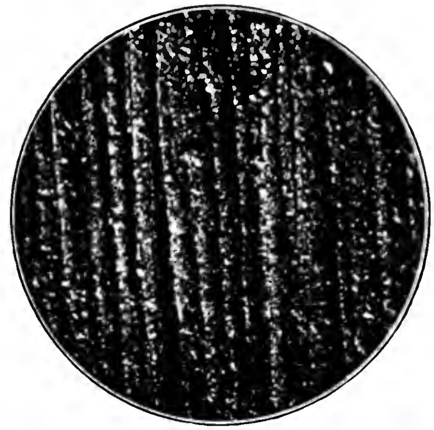

Fig. 12 Surface Shown in Fig. 11 Abraded by the Impurities in Air-Floated Graphite (100 Diameters)

end of a small fan-motor shaft, then mixing the impurities with oil and applying the mixture to the end of this wooden block, holding a microscopic slide against the block while it was revolving rapidly, and then making a photomicrograph of the abraded microscopic slide, using oblique illumination. Fig. 4 shows this abraded surface. It will be appreciated that in all of these abrading tests only those particles which are hard enough to cut glass have been brought into consideration, since all particles hard enough to cut glass are also hard enough to cut any bearing for which graphite might be used as a lubricant, whether it be a babbitt, bronze, or hardened-steel roller or ball bearing.

Artificial graphite is an amorphous graphite, as is clearly shown in Fig. 5. As already stated, it is a by-product of the electric furnace in the manufacture of silicon carbide—next to the diamond the hardest known abrasive substance—and it is difficult to remove all traces of this matter from the graphite. In the center of the view is shown a small spicule of this material, so undesirable in a lubricant. Fig. 6 likewise shows a pair of silicon-carbide crystals.

Fig. 7 is a photomicrograph of a glass surface abraded in the manner already described by using artificial graphite which had been marketed in the dry form. It is interesting to note the sharp, definite cuts in this view, characteristic of a high-class abrasive.

Fig. 8 shows an abraded surface made with an artificial-graphite compound marketed in the form of a graphite grease.

Fig. 9 shows the impurities of an amorphous natural graphite. These impurities are somewhat clotted together, though sharp and distinct crystals—mostly silica or white sand—are discernible. It will be observed that these crystals are more or less rounded, and Fig. 10 shows a surface abraded by matter resembling sea sand, but not in as clear-cut a manner as in the preceding figures.

It has sometimes been argued that the impurities of graphite could be counteracted by simply using a larger amount of graphite, just as an excess quantity of oil or grease is supplied when the quality is deficient. This, however, cannot be done with graphite. The following two photomicrographs (magnified 100 diameters) show that any abrasive impurity whatever cannot be present in the graphite without leaving its undesirable or destructive effect upon the bearing surfaces. Fig. 11 shows the smooth-milled surface of a bronze gear tooth of a rotary pressure pump which was used for pumping a mixture of substantially equal parts of water and fine air-floated graphite, the mixture having the consistency of cream. The pump was used for pumping this mixture against a head of 2 lb. per sq. in. for the purpose of forcing the graphite and water through a burr mill in order to effect proper grinding. Fig. 12 shows the surface of this tooth after it had been in use for thirty days, and demonstrates very conclusively that it is impossible to use graphite with impurities in any form between metallic wearing surfaces without having the injurious abrasive effects of these impurities.

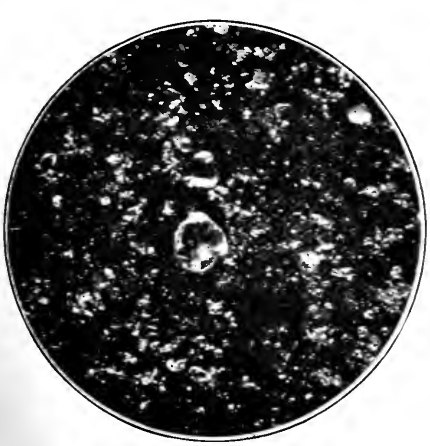

Fig. 13 Impurities in Air-Floated Graphite (100 Diameters)

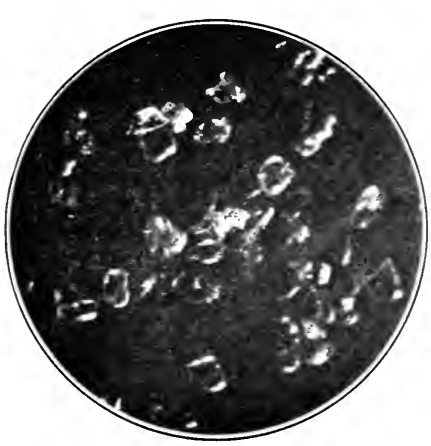

Fig. 14 Impurities in Air-Floated Graphite (120 Diameters)

Fig. 15 Impurities in Air-Floated Graphite (120 Diameters)

FIG. 16 ABRASIONS MADE BY IMPURITIES IN AIR-FLOATED GRAPHITE (120 DIAMETERS)

Fig. 13 shows the impurities separated out from the graphite-water mixture passing through the pump mentioned, also magnified 100 diameters.

Fig. 14 shows the washed crystals of another natural amorphous graphite of a very high-grade variety. While this graphite was prepared with the greatest care before marketing, the purifying process being that of air floating, it nevertheless contained a very fine-grained clear sand.

Fig. 15 shows the impurities of another variety of air-floated graphite on the market which are of a somewhat different nature, being more oblong or elongated crystals. This is due to the nature of the composition of these impurities, which are crystallized aluminum oxide. If we had these impurities in their natural colors they would represent jewels, the blues being sapphires, the yellow and canary-colored ones oriental topazes, and the whites leucosapphires. Fig. 16 shows an abraded surface made by the impurities shown in the preceding figure.

Fig. 17 shows a microscopic scale consisting of a very fine graduation on a glass surface, the smallest subdivision being 0.01 mm. (about 0.0004 in.). This scale was subjected to the abrasive test previously described, the graphite used on the small revolving block being that from which the impurities had been removed by the Bierbaum process. The surface of this slide speaks for itself—there was no abrasion, and it can be appreciated that the slightest abrasive particle on this finely graduated surface would have left its mark.

Fig. 18 shows a fungus growth in a graphite compound purchased on the market, and evidences the fact that a vegetable or animal oil was used, at least in part, in its preparation.

Fig. 19 shows the developing spore of another variety of fungus also growing in this graphite compound, and Fig. 20 still another species entering into the decomposition of the oil while it is in the process of becoming rancid.

Fig. 21 shows the fatty acid crystals in the decomposed oil. All animal and vegetable oils, chemically speaking, are salts, glycerine being the base and the acids being the organic radicals corresponding to the chemical composition of these oils. This decomposition cannot and does not occur in pure mineral oils. Graphite compounds using animal or vegetable oils should be thoroughly sterilized before they are sealed in their containers.

It has always been found difficult to apply the dry graphite to an ordinary bearing, and for that reason grease or oil has been chosen as a carrier. In the case of grease there is no difficulty—the graphite will not settle out, but in the case of oil it has given rise to the interesting study of graphite suspension. Anyone who has observed the suspension of dust in the air as revealed by a small beam of bright sunlight entering a dark room must be forced to the conclusion that this suspension of material particles in the air, that is, solid matter suspended in a gaseous medium, is due entirely to the extreme fineness of the particles, since it is observable in air which for days has been in a quiescent state. The suspension of a solid in a fluid should therefore be more easily obtainable, especially when we consider graphite and oil, since there is a film tension of oil around each particle of graphite and the oil has a positive capillary affinity with the surface of the graphite, and by the fine subdivision of the graphite its aggregate surface is increased enormously. To illustrate, if it were possible to crush a 1-in. cube of graphite to such a state of fineness that its largest particle would not exceed 0.000001 in. in diameter, the aggregate surface area of this quantity of graphite would then exceed 1 acre, whereas its

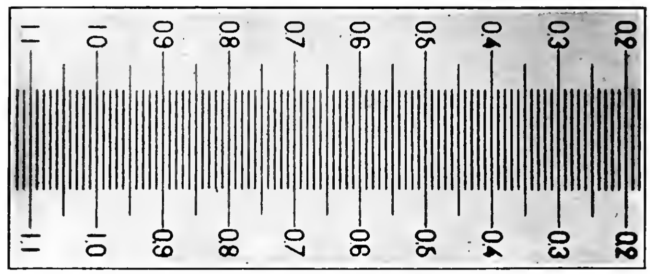

FIG. 17 MICROSCOPIC GLASS SCALE AFTER ABRASIVE TEST WITH PURIFIED GRAPHITE

FIG. 18 FUNGUS IN RANCID OIL (900 DIAMETERS)

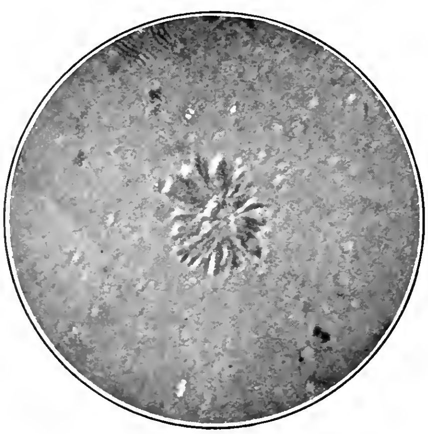

FIG. 19 FUNGUS IN RANCID OIL (900 DIAMETERS)

FIG. 20 FUNGUS IN RANCID OIL (900 DIAMETERS)

original surface area was but 6 sq. in. Such an extreme degree of fineness, however, is not necessary in order to bring the graphite out of reach of the action of gravity when mixed with a light mineral lubricating oil; in fact, microscopic observations seem to indicate that particles 1/200,000 in. in diameter are beyond the reach of the action of gravity.

It may be of interest to express the results of subdivisions mathematically and for the purpose start with an inch cube and consider the successive subdivisions in decimal order. The first subdivision gives cubes of one-tenth inch, the second hundredths, the third thousandths, and so on. Now, let A represent in numerical value the length of an edge of a cube, and we have for the successive subdivisions: A^{-3} the number of cubes, $6A^{-1}$ the aggregate surfaces of any subdivision, $6A^{-2}$ the surface of a single cube, and A^{-3} the weight of a single cube. As the subdivision is increased the weight of the particles is decreased and the relative surface increased, lessening the weight of a particle and increasing capillary affinity, and the ratio of these two values in any subdivision gives the specific buoyancy for that subdivision; that is, $6A^{-2}/A^{-3} = 6A^{-1}$; and omitting the common factor 6 we have A^{-1} for the specific buoyancy, which, from the accompanying tabulation of results, is seen to increase directly in proportion to the increased subdivision.

Fig. 21 Fatty Acid Crystals in Decomposing Oil (900 Diameters)

Fig. 22 is a graphic representation showing the law of increase of surface corresponding to an increased subdivision. Of necessity, only a limited part of the curve is given, still it shows that the curve is hyperbolic and asymptotic to the X-axis and that an infinite subdivision gives an infinite amount of surface.

From a purely mechanical viewpoint the suspension of graphite in oil should be a relatively simple matter; unfortunately, however, when the particles of graphite are fine enough to be able to defy the force of gravity, they are then subject to another force known as the Brownian movements. Under the latter force the graphite particles are subject to what approaches perpetual motion; it is not a continued movement in one direction, but a zigzag course, caused by the free electrons striking the particles of graphite. A particle on being struck starts with a jerky movement and continues moving until arrested by the fluid friction of the oil, provided it has not already been struck by another electron causing it to bound off in another direction. An observer who saw this fascinating action for the first time expressed himself to the effect that the particles seemed to be on a St. Vitus dance. During these erratic movements the particles of graphite collide with each other and as a result adhere; they in turn are struck by other particles, and in this manner there is gradually built up a mass of adhering particles which is subject to the action of gravity and results in settling out.

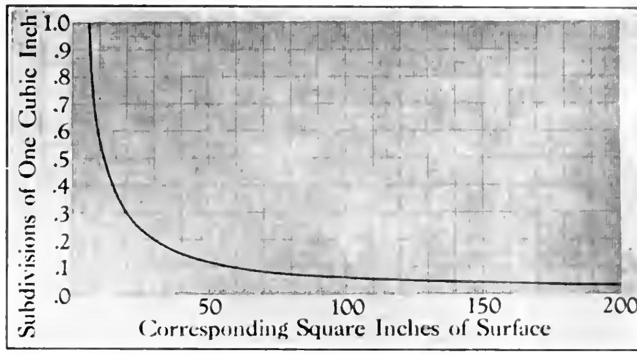

Fig. 22 Curve Showing Increase of Surface with Increased Subdivision

Size of cube, A	Number of cubes, A^{-3}	Aggregate surface, $6A^{-1}$	Surface of single cubes, $6A^{-2}$	Weight of single cube, A^{-3}	Specific buoyancy, A^{-1}
1.	1	6	6	1	1
0.1	10^3	6×10	6×10^{-2}	10^{-3}	10
0.01	10^6	6×10^2	6×10^{-4}	10^{-6}	10^2
0.001	10^9	6×10^3	6×10^{-6}	10^{-9}	10^3
0.0001	10^{12}	6×10^4	6×10^{-8}	10^{-12}	10^4
0.00001	10^{15}	6×10^5	6×10^{-10}	10^{-15}	10^5
0.000001	10^{18}	6×10^6	6×10^{-12}	10^{-18}	10^6

It is obvious, from what has gone before, that the greater the number of free electrons present in the oil, the more rapidly the coagulation and settling-out process should proceed, and such is the case. It is fully borne out by experience that the addition of a free acid or salt greatly accelerates the precipitation; in fact, any electrolyte present has this effect, such as the acid residue or its resultant neutralized salt re-

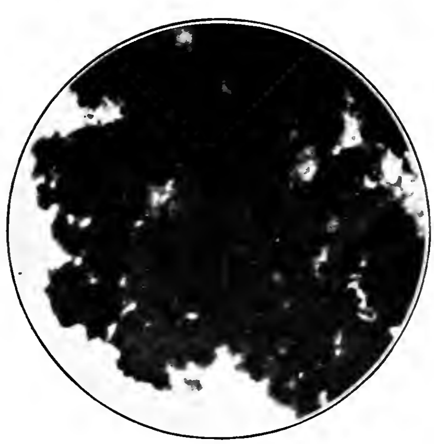

Fig. 23 Coagulation of Graphite in Oil (1200 Diameters)

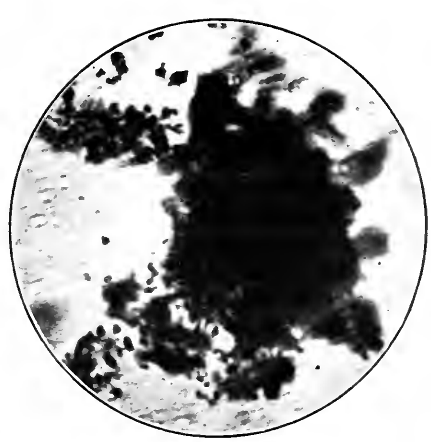

Fig. 24 Coagulation of Graphite in Oil (1600 Diameters)

maining in a lubricating oil after refining, or the rancidity of an oil, all tending to increase the number of free electrons and the precipitation of the fine particles of graphite.

Various expedients have been resorted to in order to effect so-called permanent suspension of graphite in oil. The one most commonly made use of is that of coating the finely ground particles with a foreign substance and then effecting a high dispersion of these coated particles throughout the oil. The coating material is usually a vegetable compound; if an oil it should be one insoluble in the mineral oils, such as castor oil, or it may be tannic acid or an allied tannin compound. Fig. 23 shows the precipitation of a commercial variety of oil-coated suspended graphite. Fig. 24 shows one more highly magnified, it being the precipitation of a commercial variety of tannin-coated suspended graphite, the largest particles of which do not exceed 1/250,000 in. in diameter.

The value of a so-called permanent suspension of graphite in oil is more fanciful than real, for the reason that in all such attempts the graphite is ground to such an extreme degree of fineness that this very fineness mitigates against its being useful. In a bearing properly constructed, lubricated and in operation the bearing surfaces are completely separated by the oil film and the extremely fine particles of graphite simply float in the film, exerting no appreciable effect either beneficial or otherwise.

The time, however, when graphite can be of benefit and perform its only and supreme function is when the oil film between the bearing surfaces is destroyed and the graphite serves as a solid lubricant. The graphite is carried between the bearing surfaces by the oil, and in the same manner, when the oil film is destroyed by being squeezed out, the graphite particles are carried along with the oil from between the bearing surfaces until the film is reduced to a thickness corresponding to the dimensions of the largest particles of graphite which at this stage will be arrested and held between the surfaces. Upon the complete destruction of the film these particles so held are crushed and imbedded into the grain and pores of the surfaces and thus are made to perform their function of solid lubrication. It is evident that the smaller the particles are, the less will be the amount of graphite so intercepted between the bearing surfaces; therefore, a given amount of graphite is most efficient if it exists in particles of the largest possible size. The more nearly permanent a graphite suspension is, the more nearly does it approach the colloidal state and the more completely is it carried out from between the bearing surfaces when the oil film is being destroyed.

This can be demonstrated in a most striking manner by taking a light-colored lubricating oil, thoroughly mixing with it a definite amount of graphite, and then placing it between two highly accurate glass surfaces and observing the amount of color left after a definite pressure has been applied for a definite time, while maintaining a fixed temperature. An amorphous natural graphite ground so that its coarsest particles did not exceed 0.0002 in. showed under the foregoing conditions an almost opaque surface, while a commercial graphite suspended in tannin and whose largest particles did not exceed 1/250,000 in., showed a substantially colorless surface. This is readily accounted for by the fact that the largest particles in the one graphite contained 125,000 times the bulk of those in the other, a condition existing at the time the glass surfaces in each case had approached each other near enough to arrest the flow of the respective particles.

The carbon content of graphite is not an indication of its lubricating value or its purity, for the reason that the percentage of amorphous carbon in some varieties is comparatively high. Amorphous carbon, or carbon not completely graphitized, can best be classed as an inert impurity; its presence always shows extreme blackness. The same is true of another common impurity, hydrogen, or a hydrocarbon; this is also black, whereas the purest graphite is a dark steel-gray when mixed with a clear white oil. The chemical laboratory can only give valuable information on the subject of the graphites when the work is done by an expert or specialist.

Advisory Committee for Aeronautics

The report of the Advisory Committee for Aeronautics (British) for the year 1916-1917 has just been issued. Following the rule of the immediately preceding years, it omits the technical appendices which in peace time were the principal and most interesting parts of the reports.

Strength of Construction. A number of questions relating to strength of construction have been investigated, and some general conclusions have been reached tending to simplification of strength calculations. The basis is to be adopted in design to secure adequate strength in high-speed machines, with the power to rapid maneuvering essential in aerial fighting, is a matter demanding the most careful consideration. To secure the highest possible speed it is necessary to keep down the weight to a minimum, and the best compromise between these two opposed conditions does not admit of precise determination. This question has received attention, and the manner in which strength varies with increase of dimensions has also been made the subject of investigation. Cases in which vibration has been set up have been examined, and calculations relating to the strength of the body structure have been made.

Engines. A number of questions relating to engines and engine design have been submitted by the Air Board for consideration by the Engine Sub-Committee. These have required very careful investigation, and the sub-committee has been closely occupied since its formation with the various problems which have arisen. Experimental work has been carried out, by request of the sub-committee, at the Royal Aircraft Factory; and the sub-committee has received much assistance in the examination of special questions both from manufacturing firms whose works have been visited.

Light Alloys. The use of light alloys in the construction of aircraft and aircraft engines is becoming of rapidly increasing importance, and improvements in the production of light alloys will have great effect on future development. The investigations relating to light alloys which have been in progress for many years at the National Physical Laboratory have been continued, and results of special interest have been achieved during the past year. Suggestions have been made to the Air Board by the Committee which may, it is hoped, help to secure the best conditions in manufacture for the development of such alloys. The formation of the Light Alloys Sub-committee will be of great assistance in coördinating the work on light alloys which is being done in various quarters, and in collecting the information resulting from experimental investigation and manufacturing experience. Experimental work has been carried out for the sub-committee at the Royal Aircraft Factory, the University of Birmingham, the National Physical Laboratory, and elsewhere, and arrangements have been made for placing the information obtained at the disposal of manufacturers.

Other subjects treated in the report are: Experimental work in aerodynamics; fabrics, dopes, etc., and investigations relating to seaplanes.

SYMPOSIUM ON STEAM LOCOMOTIVES HELD BY THE MINNESOTA SECTION

A SYMPOSIUM on steam locomotives was held by the Minnesota Section of the Society on the afternoon and evening of March 10, 1917, at the Main Engineering Building of the University of Minnesota. Seven papers were presented, as well as a discussion on Metal Alloys Used in Locomotives, by Prof. G. L. Hoyt, and a short address by Dr. Ira N. Hollis, President Am.Soc.M.E. J. V. Martenis, Mem.Am.Soc.M.E., opened the afternoon session with an address on the Historical Development of the Locomotive, which was profusely illustrated with lantern slides and later illuminatingly discussed at some length by J. J. Flather, Mem.Am.Soc.M.E. Papers were then read which had been prepared by Messers. Foque, Toltz, Bourne, Muhlfeld, Ostermann, and Basford, extended abstracts of which immediately follow.

MODERN LOCOMOTIVE PRACTICE

By T. A. FOQUE, MINNEAPOLIS, MINN.

Member of the Society

IN passenger service the locomotive best suited to present-day requirements is the 4-6-2, or Pacific type, which is almost universally used where a tractive effort of from 42,000 to 45,000 lb. is required. Where very heavy grades are encountered, or where long, heavy trains are operated on even moderate grades, the 4-8-2, or Mountain type of locomotive, is becoming popular.

In freight service the 2-8-2, or Mikado type, is now largely used in place of the 2-8-0, or Consolidation engine, where a tractive effort of from 50,000 to 60,000 lb. is required. With a 63-in. driving wheel it is not only good for heavy freight service, but is well adapted to fast freight work. On lines with very heavy grades this type of engine, with the addition of a fifth pair of driving wheels, is designed for a tractive effort of from 65,000 to 83,000 lb. and is known as the Santa Fe type. Increased boiler capacity and factor of adhesion make this type of engine better for heavy slow service than the Mikado type.

On exceptionally heavy grades, extending over a large portion of a division, Mallet compound engines are quite generally used in 2-8-8-0 and 2-8-8-2 types. The tractive effort of existing engines runs from 91,000 to 103,000 lb.

For pusher service over heavy grades triple-compound types, 2-8-8-8-2 and 2-8-8-8-4, are now being used by two railroads. These have two high-pressure and four low-pressure cylinders, and the rear set of driving wheels and truck are located under the tender.

One road is now experimenting with a 2-8-2-2-6 type of engine, consisting of the application of the running gear and machinery from a retired Mogul locomotive to the tender of an existing Mikado locomotive.

In switching service the ordinary or 0-6-0 type is in most common use, but some 0-8-8-0 Mallets with a tractive effort of 100,000 lb. are now being used in hump-type classification yards. Considerable time is saved on account of taking trains just as delivered by road engines and putting them over the hump and classifying. For heavy general switching service the 0-8-0 type, running up to 70,000 lb. tractive effort, is used with success.

Comparative few locomotives are now built without a superheater. The economy following the use of this device is very marked and existing engines have been greatly improved by the addition of the device. To reduce the fuel consumption further the use of brick arches supported on water tubes is very common, and modern improvements in the design of the arches have made their use practical where formerly they gave considerable trouble.

On all road locomotives and some switching locomotives, outside valve gear of the Walschaerts type is used almost altogether. Accessibility, better distribution of steam and freedom from breakdowns make outside gear very desirable. On the Soo Line we have modified the ordinary type of gear by taking our motion for the lap-and-lead lever from the main rod instead of the crosshead. This is quite a marked improvement in that it gives us much better port openings.

The majority of engines now built are so heavy that the usual form of reversing mechanism is not suitable, and power reverse gear, either of the screw pattern or operated by steam, has been introduced with very satisfactory results.

Pneumatic fire doors relieve the fireman of much work and are beneficial to an engine in that they greatly reduce the time in which a door is kept open.

One of the great troubles with heavy locomotives is found in the design of the main driving boxes, and the brass in the ordinary type of box may be renewed two or three times before an engine requires a general shopping. To eliminate this expense and wear on an engine, boxes 20 in. long or longer are now used on the main journals.

The old practice of keeping steam pipes within the smokebox has nearly been done away with, and we now use outside pipes to the steam chest, eliminating in a large measure the trouble with leaky joints and giving us easier access to the smokebox appliances.

The advent of long freight trains called for air compressors of much greater capacity, and we now use two single-stage pumps or one compound pump.

In recent years much more attention has been given to proper air openings in the ashpans and dumping mechanisms which will allow of frequent and easy disposal of the cinders. On some large locomotives, especially where a low grade of fuel is used, the work of firing has become too much for one man and mechanical stokers are now being used, and some of them are now doing very good work.

Within a year or two a few roads have experimented with an apparatus for burning pulverized fuel. The question is one of much interest, for there are in certain parts of the country large deposits of fuel wholly unsuited to locomotive use in its present form, but which may in powdered form prove not only satisfactory but very economical.

In locomotive tenders the tendency today is toward those of large capacity, which frequently permits of the avoidance of water supplies which are exceedingly bad. To save labor and because of legislation, tenders are now constructed with coal hoppers of such design that the coal will automatically be placed within easy reach of the fireman. Hoppers which cause the coal to come down and forward by gravity are the cheapest and best, but in some cases mechanical coal pushers have been installed.

Special attention has been given for a number of years to truck design, with a view to eliminating dangerous roll at high

speeds. In many derailments the forward tender truck is the first to leave the track. Comparatively slight depressions in the track may set up a rolling of the tender, which, accompanied by a reverse roll of the locomotive, will cause the forward tender wheels to jump. The connections between the locomotive and tender also have a bearing on this, and one connection has been designed which is a vast improvement over anything used before.

Important as is the design and construction of a locomotive, the vast majority of troubles in locomotive operation may be found in lack of maintenance. In certain parts of the country we are sorely tried with water heavy with incrusting salts. It is not an easy matter to handle bad water successfully, but in most cases it can be done. In repairs to machinery there is but one sensible and economical course to follow: when defects appear, apply the remedy. It has been demonstrated without question that it is more economical to keep up the running repairs and not wait until a locomotive needs a general shopping.

THE LOCOMOTIVE OF TODAY

By MAX TOLTZ, ST. PAUL, MINN.

Member of the Society

The steam locomotive is a power plant which has to be admired, because if the same amount of power is developed in a stationary plant it will take up from five to ten times the amount of space. Modern large locomotives are developing now as high as 3000 hp., with a drawbar pull of very nearly 105,000 lb.

Ten years ago wide fireboxes were already used to a considerable extent, also brick arches supported by water tubes. Moreover, extra water tubes were added in the firebox to improve the water circulation and to increase the heating surface of the boiler.

The Walschaerts valve gear succeeded the Stephenson not because the Walschaerts gives the better steam distribution but because it facilitates the strengthening of the frame of the locomotive. The use of metal alloys has also been introduced for the purpose of strengthening parts of the locomotive.

In 1905 the writer pointed out that in applying superheaters to locomotives a high superheat should be employed to obtain economy in water and coal consumption. At that time it was the general consensus that 100 deg. of superheat would be all that was necessary for this purpose.

In 1906 he applied the first Schmidt fire-tube superheater to the locomotives in the States. Not less than 250 deg. of superheat were obtained, which resulted in an average saving of 25 per cent of coal and 35 per cent of water. Since 1908 or 1909 the fire-tube superheater has come to stay with us.

To improve the combustion and at the same time to force the capacity of the locomotive boilers by burning more coal per square foot of grate surface, automatic stokers have been applied to locomotives with great success. The present stoker has given good satisfaction, yet the combustion of coal can still be improved and is being improved by the adoption of pulverized coal on locomotives. Although the latter is in an experimental stage at present, there is no doubt but that it will be a success.

Another improvement on the locomotive, which will no doubt be perfected, is the heating of the feedwater, either with the waste gases or with the exhaust steam.

If we compare the economy of the locomotive of twenty years ago with that of the locomotive of today we know that we are getting over 50 per cent more work than we did then. Yet we should not be satisfied with this, but should strive to make the locomotive a power plant second to none.

METAL ALLOYS USED IN LOCOMOTIVES

By G. L. HOYT[1]

Every railroad man who is concerned with the design of a locomotive knows that heat-treated steel has better properties than annealed, for by heat treatment we are able to produce certain properties that can be produced in no other way. I have found out, however, in talking with various railroad men, that the chief reason why they are not ready to adopt heat-treated parts is that heat-treated steels do not stand up any better than ordinary carbon steels, and that in some cases special steels give more trouble than ordinary carbon steels. The reason given is that the producers of these parts are not in a position to heat-treat material of that quality on a commercial basis to sell for such a price that the railroads can effect an economy in buying. The practice at present seems to by merely to anneal these various parts. A locomotive axle will be forged out, the steel used being the ordinary good grade of open-hearth steel; it is then heated up to the critical point and air-cooled down slowly. The object, I take it, is to insure uniformity and absence of internal strains. Whether or not a satisfactory structure is produced is of entirely secondary importance. When I mention internal strains, I hit the nail on the head as to why heat-treated steels are not used generally in locomotive practice. There can be no doubt about the advantages which they possess over ordinary carbon steels, and if it is impossible at present to obtain heat-treated steels for locomotive construction, something should be done about it.

If I can see the signs of the times correctly, there is a necessity for all the economy possible in railroad operation, which is why the question of using heat-treated steels in locomotive construction is becoming more and more important. It is possible to produce steels that far surpass those entering into locomotive construction. In gun construction the United States Government and the steel plants got together and are now successfully manufacturing heat-treated gun parts. Hadfield projectiles are probably the most difficult of all materials made of steel to produce satisfactorily, the internal strain serving to weaken the resistance of the material.

What has been done in other cases can be done in regard to any part about a locomotive. I can see nothing inherently difficult about heat-treating locomotive parts. Whether or not those methods are developed depends upon the demand made upon the steel plants by the railroads to produce the desired material. If the roads feel that there would be an economy in using heat-treated parts, undoubtedly there would be a great attempt on the part of the steel plants to produce that material.

When you are getting a certain grade of steel, you may have certain specifications, but 30 per cent elongation, etc., tell almost nothing about the steel, that is, so far as whether the axle is going to stand up in service, for the tests which are used to bring out the superiority of heat-treated steels are of an entirely different character. Take a locomotive frame, or the axle. Its parts are subjected to vibratory strains and stresses. Say that the locomotive axle runs hot, and that it is cooled off by water, ice, or snow, and a crack is started. What is the effect of the presence of a crack in a locomotive axle, in

[1] Assistant Professor of Metallurgy, University of Minnesota.

one having a fine-grained structure, and one having a coarse grain? In considering this, the real value of heat treatment is brought out, and something that is not shown by ordinary tensile tests. A crack is of much less consequence in the case of softened steel than in the case of annealed steel. Internal strains are eliminated in annealed steel, but the same treatment which produces the fine-grained structure also eliminates internal strains. It is a question of properly conducting the heat treatment, and the trouble is that the steel plants either work carelessly or for some other reason do not take particular pains to heat-treat the material. If the railroads as a whole would take up this question and push it as they pushed the question of steel rails a few years ago, I have no doubt but that they would be getting properly heat-treated steels.

As far as special steels are concerned, the problem is different. Their cost at present is almost prohibitive. Nickel steels, etc., are now in such demand on account of their use in the manufacture of munitions and automobiles that no considerable portion or amount of them can be diverted to such a use as this, and unless they are heat-treated they are not at all worth the additional cost.

When using special steels which have been heat-treated, why do those in charge of locomotive construction insist on using the same designs? A certain part is made of ordinary carbon steel annealed. As an experiment, a railroad will buy that part made out of special steel, heat-treated, and expect to effect an economy. No metallurgist would advise leaving the design the same: if it is correct for carbon steels, it is not correct for special steel. If you leave the cross-section the same, you leave the weight of the section the same, and the price of the heat-treated part consequently seems exorbitant. The management, however, probably takes the stand that it is better to leave the section the same and get the improvement by substituting a good steel, but this does not give a satisfactory basis for comparison.

Another point I want to bring out is the service you can expect from special steel as compared with carbon steel. A locomotive equipped with special-steel heat-treated parts is usually found in the shops as frequently as other locomotives, but the reason is that the heat treatment has not been carefully done. I am convinced of that when told of the failures of the heat-treated parts.

In closing, let me compare the service of annealed carbon steel with the service of special steel properly treated. The carbon steel is ductile and has a certain amount of strength, but in practically every other way it is weak, and particularly so if a flaw develops. If a small crack starts working its way through the axle, right there the annealed axle is weakest. It is on account of the large percentage of free iron. One of the worst things that could be done for a steel axle from that point of view would be to anneal it, for this would produce the free iron. One thing that counteracts this is the removal of internal strains. A heat-treated steel axle, whether carbon or special, designed so that it will have the same static strength, if injured in any way has several times the resistance of annealed steel. The heat-treated steel is less apt to be tricky than the annealed.

The saving effected by using special steels results chiefly from cutting down the weight of the reciprocating parts; but unless these are designed with the properties of the heat-treated steel in mind, there can be no real comparison drawn. The work done up to the present time does not lead to a reasonable comparison between special and annealed steels, and until that is done properly, we are not in a position to say whether the special steels should be condemned.

SUPERHEATER DEVELOPMENT IN AMERICA

By GEORGE L. BOURNE, NEW YORK, N. Y.

Member of the Society

Of all the devices or improvements which have been introduced in American locomotive practice, the fire-tube superheater is by far the most notable. By its economy in fuel and water it brought the heaviest locomotive well within the capacity of the average fireman. Here was a device exactly suited to American practice—one with a low maintenance cost to fit in with the high wages of American mechanics; with increased boiler capacity of approximately 35 per cent, to act as a reservoir of power, ready for use when most needed; and finally, with a fuel economy of from 20 to 25 per cent.

As a result of the suitability of the superheater to American railroad requirements, there are today over 21,000 superheated locomotives in service or under construction in the United States and Canada. During the past year superheaters were applied to approximately 95 per cent of all the standard-gage steam locomotives built in the United States.

The general trend of superheating engineers has been toward a higher superheat—increasing the gas area available for superheat at the expense of the boiler tubes. This, it is true, tends toward a lower boiler efficiency on account of the necessary loss in water-heating surface, but the resultant increase in the efficiency of the entire machine offsets this many times over.

The results obtained on the Long Island and Lehigh Valley Railroads, which have used steam at a temperature in excess of 750 deg. fahr., have clearly demonstrated the possibilities of higher steam temperatures. As 200 deg. of superheat is amply sufficient to overcome condensation losses in the steam pipes, valves and cylinders, it is evident that the increased efficiency obtained by any superheat in excess of 200 deg. fahr. must be entirely due to increased volume of the steam per unit of weight. This is an almost constant increase in volume for each degree of temperature, and as far as calculations have been worked out for superheated steam, there is no limit to this increase. There can be no doubt that the limit of superheated steam temperatures for the most economical and efficient operation is only fixed by the ability of the exposed machine parts to withstand the higher temperatures.

While superheated steam was originally regarded as of benefit, primarily, to heavy road locomotives using steam for long, continuous periods, later developments have proved its desirability for the more efficient operation of locomotives in all classes of service. Perhaps the most notable example of this tendency is in the superheating of switching locomotives. While the degree of superheat obtained in switching service is naturally not as high as on road engines, it is, nevertheless, enough to reduce condensation losses greatly, which in this class of service amount to over 40 per cent of the total energy developed by the boiler.

As a result, there are today over 1300 switch engines which have been equipped with superheaters, and a steadily greater proportion of the switching locomotives built are being superheated. It is significant in this connection to note that those railroads which have made a trial of superheated switch engines are now foremost in applying superheaters to their existing yard power.

The original design of the fire-tube superheater was so sound that comparatively few changes have been necessary in adapting it to the peculiar requirements of American railroads. But there have been certain modifications which, although of a minor character, are nevertheless worthy of attention.

The first important change was in the redesign of the through-bolt header. Experience showed that the original design gave entire satisfaction when correctly manufactured, but to furnish insurance against inferior material or improper methods in casting, a new design was prepared in order to counteract, as far as possible, the results of possible errors made in manufacture. In the new through-bolt header an additional air space has been provided between the walls of the superheated and saturated compartments in order to protect the casting from the rapid transfer of heat between these compartments, as insurance against the development of cracks between the unit seats in the lower face of the header.

The second great advance was the improvement in the design of the unit return bend. This consisted in producing a welded return bend to replace the original cast-steel bend, with consequent elimination of all mechanical joints in the unit. This machine-forged return bend, which is now almost ready for the market, will have a heat resistance equal at least to that of the old cast-steel return bend. At the same time it will have all the advantages which go with freer steam passages and a minimum restriction to the flow of gases through the superheater flues, with the complete elimination of all leakage due to threaded connections in the unit.

THE USE OF PULVERIZED FUEL ON LOCOMOTIVES

By JOHN E. MUHLFELD, NEW YORK, N. Y.

Member of the Society

As the limiting factor of a modern steam locomotive is the evaporation and superheat production capacity of the boiler, the rate and effectiveness of the combustion become the controlling elements. While there is no limit to the amount of fuel that may be mechanically supplied to a locomotive firebox, there is a decided limitation to the amount of fuel that can be burned on a given grate area and effectively utilized.

When coal is burned on grates a rate of about 50 lb. of run-of-mine grade,—or about 60 lb. of lump grade of bituminous coal,—is the maximum allowable per sq. ft. of fire surface per hr. for the greatest practical boiler efficiency. However, as this rate of firing limits the consumption to a total of from 3000 to 6000 lb. per hr. for the average modern locomotive of great power, and as the actual coal that must be supplied to the firebox by mechanical stoking in order to maintain the boiler pressure frequently reaches a rate of 150 lb. per sq. ft. of grate area per hr., or a total of from 9000 to 15,000 lb. per hr., the boiler efficiencies often run as low as from 55 to 45 per cent and even less.

The necessity for eliminating grates if much over 12 lb. of water is to be evaporated per sq. ft. of water-heating surface per hr., is therefore quite apparent provided reasonable efficiency is to be obtained, and this brings us to the problem of burning solid fuel in a manner that will overcome the principal deficiencies in the steam locomotive and enable it to maintain its present position in the steam-railway field and to assist further in reducing the high cost of railway living.

As I presented before the 1916 Annual Meeting of the Society an exhaustive report on Pulverized Fuel for Locomotives, which, with the discussion, was abstracted in THE JOURNAL,[1] I will make this paper quite brief.

When solid fuel is burned on grates in a modern locomotive, from 45 to 70 per cent of the heat is absorbed by the boiler. Of that which is wasted the majority is due to incomplete combustion, sparks, cinders, smokebox gases and combustible in the ash. Owing to the necessarily limited grate area, the high draft essential to induce sufficient air through the grates for combustion causes these enormous losses through unburned gases and fuel that are exhausted from the stack or carried into the smokebox and ashpan.

Generally speaking, it is necessary to break up any fuel to such uniform size that the oxygen in the air can unite perfectly for combustion. A deficiency in this respect results in some portions of the fuel passing off as unburned hydrocarbons, and other portions being left as incompletely burned coke. For the best results coal should be sized to about 3-in. cubes for burning on locomotive grates, but as this is now quit impracticable, due to the methods of mining and the cost, a mixture of fine and large coal is usually supplied, which tends to burn irregularly and results in a reduction of boiler capacity and efficiency.

As a 1-in. cube of coal exposes but 6 sq. in. of area for absorbing oxygen and liberating heat, but when pulverized to the proper fineness will expose from 20 to 25 sq. ft., the first essential for complete combustion is the breaking up of the fuel into dry minute and uniform particles. Then, by diffusing these so that each may be surrounded with the right quantity of air for complete combustion, it will be possible to burn practically all of the available combustible, regardless of the percentage of non-combustible.

Any solid fuel that, in a dry pulverized form, has two-thirds of its content combustible, is suitable for pulverizing, and to produce the best results should be mechanically dried and milled so that it will be of about the same dryness and fineness as portland cement. The total cost to prepare pulverized fuel properly in a suitably equipped plant will range from 15 to 45 cents per ton, and for a railway coaling station of average capacity will be less than 25 cents per ton.

In the process of burning pulverized fuel the fuel in the enclosed tank gravitates to the conveyor screws which carry it to the fuel and pressure-air feeders where it commingles with the air. It is then blown through the connecting hose to the fuel- and air-delivery nozzles and blown into the burners. Additional air is supplied and the mixture is drawn into the firebox by the front-end draft. Additional air is supplied in the furnace where complete combustion of the fuel in suspension takes place. The liquid ash runs down the under side of the roof and the sides and ends of the furnace and is precipitated into the self-cleaning slagpan, where it solidifies into a mass that can be readily dumped.

The blower is driven by a constant-speed steam turbine which requires no regulation or control. The fuel conveyors, feeders and comminglers are driven by a variable-speed steam turbine which is controlled by the fireman by means of a handwheel conveniently located in the cab.

The smokebox-gas analysis will average between 13 and 14 per cent of CO_2 when coal is fired at the rate of 3000 lb. per hr.; between 14 and 15 per cent at the rate of 3500 lb. per hr., and between 15 and 16 per cent at the rate of 4000 lb. per hr., so that as the rate of combustion increases there is no falling off in the efficiency, as obtains when coarse coal is fired on the grates.

The waste of fuel from the stack, where coal having a large percentage of dust and slack is used; the lowering of the firebox temperature and draft, due to opening of the fire door; and the resultant variation in steaming and general results under high rates of burning fuel on grates, where all of the foregoing factors are involved, are entirely eliminated.

[1] THE JOURNAL, December 1916, p. 983; January 1917, p. 48; February 1917, p. 141.

The uniformity with which locomotives can be fired is indicated by the fact that the regularly assigned firemen can maintain the steam within a variation of 2 lb. of the maximum allowable pressure, without popping off.

While the smokebox temperatures have varied between 425 and 500 deg. fahr., the superheat in the steam will vary between 200 and 325 deg. fahr., depending upon the rate of working.

With pulverized fuel a locomotive having the boiler filled with cold water may be brought under maximum steam pressure within an hour, and the fuel feed then stopped until it is called for service. When standing or drifting at terminals or on the road the fuel feed can also be discontinued, as the steam pressure can always be quickly raised. After the trip or day's work the locomotive can be immediately stored or housed, the usual ashpit delays being entirely eliminated.

From the actual operation of steam locomotives in regular train service, the use of pulverized fuel has demonstrated in particular the practicability of eliminating smoke, cinders, sparks and fire hazards; increasing drawbar horsepower per hour per unit of weight; reducing non-productive time at terminals; improving the thermal effectiveness of the steam locomotive as a whole; utilizing otherwise unsuitable or waste fuels; eliminating arduous labor; providing greater continuity of service, and producing more effective and economical operation and maintenance.

ECONOMY OF THE LOCOMOTIVE SUPERHEATER

By R. M. Ostermann, Chicago, Ill.

Member of the Society

In the fire-tube superheater the superheater heating surfaces are interspersed with the evaporating surfaces of the boiler, and a very compact arrangement is thereby created with numerous parallel gas passages, resulting in best utilization of the heat contained in the gas. As a matter of fact, at large loads relatively low smokebox temperatures—that is to say, a high heat absorption of the combination—are readily obtained.

In the locomotive the superheat increases at a nearly constant rate with the indicated horsepower, and varies in a generally similar manner with the draft and the rate of evaporation, both of which are automatically regulated to suit the load by the smokebox exhaust. The superheater is therefore what might be called a "power booster" for the locomotive, and this is a very valuable feature from an operating point of view. The more steam demand there is made upon the boiler—the higher the rate of evaporation, the more intense is the action of the superheater in decreasing the specific steam consumption of the locomotive. The boiler without the superheater does not possess this feature; on the contrary, the priming rather increases the steam rate very fast when the boiler is forced.

The action of the superheater in boosting the steam temperature and power of the locomotive probably finds its limit of benefit when too great an increase of cut-off halts a further reduction of specific steam consumption. Just at what speed and power this takes place naturally depends upon the proportions of the boiler as compared with the cylinders and wheels, and it is a problem of the designer to provide the boiler with its proper share of evaporating and superheater heating surfaces so that the largest possible amount of sustained horsepower can be had at the speed at which the engine is required to operate normally.

In the superheater locomotives that are operated in this country, only part of the tube-sheet area is occupied by the enlarged smoke tubes in which the elements or units of the fire-tube superheater are located. It goes without saying that when an existing locomotive boiler is given a superheater and when, for the purpose of installing the superheater, a part of the tube evaporating surface in the shape of the small smoke tubes has to be removed and enlarged smoke tubes substituted therefor, a certain part of the total evaporating surface must be sacrificed. Given a certain tube-sheet area, the total evaporative heating surface of course increases the smaller the diameter of the smoke tubes selected. That feature is the one which will limit the number of superheater units which can be installed in a given boiler, and with it the capacity of the superheater. The only way in which the capacity of smoke-tube boilers with fire-tube superheaters can be further increased is to subdivide more finely the gas stream to provide a still closer intermingling of superheater and evaporative heating surfaces, for the installation of superheater units of still smaller diameters within smaller smoke tubes. The large smoke tubes which are now used in this country are $5\frac{1}{2}$ in. and $5\frac{3}{8}$ in. in outside diameter, with $1\frac{1}{2}$-in. outside-diameter superheater-unit tubes. These dimensions can be successfully reduced, as has been demonstrated on European locomotives and also in power plants of steamboats with Scotch marine boilers.

Substantial savings in coal and water per unit of power developed are now being obtained in every-day operation. As a rough average, a coal saving of 25 per cent and a corresponding water saving of 35 per cent can be expected and thermally accounted for with the knowledge that we have of the average amount of cylinder condensation that exists in saturated-steam locomotives. Inasmuch as the operating value of a locomotive depends upon the maximum amount of horsepower which it can develop, and inasmuch as a great many railroads when they install superheaters are more vitally interested in an increase of the locomotive's capacity than in the fuel saving, it frequently happens that the excess of boiler capacity which becomes available after reducing the specific steam consumption of the engine is reutilized by making greater demands upon the engine's hauling power, that is to say, by lengthening the cut-off or operating it at a higher speed than before it was superheated.

Comparing, then, two locomotives with identically the same engine and wheels, and assuming further that it would be possible to take sufficient horsepower out of the superheater engine in order to make it burn the same quantity of coal as the saturated engine per hour without an appreciable increase of coal consumption per indicated horsepower developed, then, on the basis of the fact that the superheater engine can produce 1 hp-hr. at 25 per cent less fuel than the saturated engine, one can inversely figure that the superheater engine has 33 1-3 per cent more cylinder horsepower and from 45 to 55 per cent more drawbar horsepower than the saturated engine. The superheater engine could, then, haul 45 to 55 per cent more tonnage at the speed of the saturated locomotive, working at a correspondingly larger cut-off. In practice, however, such an increase of tonnage is rarely possible, for the reason that the superheater locomotive has no more starting effort than the saturated locomotive of the same engine dimensions, and particularly on heavy grades the starting feature governs the tonnage that can be handled. An increase in speed, in order to utilize the greater sustained boiler capacity available, is often possible, but hardly ever to the extent that all the excess of boiler capacity potentially existing can be utilized. It can

be taken for granted that part of the benefits of superheating are always reaped in the form of fuel and water saving, and all data from comparative runs, where the superheater locomotive was called upon to develop haulage effort greatly in excess of the saturated locomotive, show a substantial fuel and water saving.

LOCOMOTIVE FEEDWATER HEATING

By GEO. M. BASFORD, NEW YORK, N. Y.
Member of the Society

Heating the feedwater of a locomotive by heat otherwise wasted is a fairly general practice in all the more progressive European countries, but experiments along these lines have been but spasmodic in this country up to a very recent period. This does not mean that the motive-power officers of American railways are not alive to the possibilities offered in the shape of economy or increased capacity by a practical feedwater heater, but it simply indicates that the tremendous development of the locomotive in this country in the past fifteen or twenty years has made it necessary to neglect many features for the time being which are known to be well worth while. It appears, however, that the time is now about ripe for taking up the subject in a systematic and thorough manner, and a discussion of the principles and possibilities of feedwater heating on locomotives will not be amiss at this time.

The following table gives the general distribution of the heat in a locomotive, and these figures, we believe, are fairly typical of good practice and average results.

Total heat in the coal, per cent		100.0
Loss in unconsumed coal and heat in ashes in the ashpan, per cent	5.3	
Loss in dry smokebox gases and vapor of combustion, per cent	18.0	
Heat through boiler heating surfaces (includes superheater), per cent	76.7	
	100.0	100.0

Investigating further the distribution of the heat after it has entered the steam, it will be seen by the table following that 65.2 per cent of the total heat of the coal is discharged in the exhaust steam, mostly in the form of latent heat.

Heat in steam as shown above (boiler efficiency), per cent	..	76.7
Loss by radiation, per cent	3.5	
Loss in friction of locomotive, per cent	1.0	
Useful work at drawbar (thermal efficiency of locomotive), per cent	7.0	
Heat discharged in exhaust steam, per cent	65.2	
	76.7	76.7

The exhaust steam of course does some work in producing draft and cannot all be considered as a loss, but calculations can be made which will easily show that it is very largely loss and that a small proportion of this heat could perform the work of producing draft satisfactorily.

A locomotive to give the results presented in the above tables would be working at an economical rate, probably burning about 60 lb. of coal per sq. ft. of grate area per hr. Having 76 sq. ft. of grate area and coal of 14,000 B.t.u. heat value, this would make the total heat available in the coal equal 63,840,000 B.t.u. per hr.

As the boiler efficiency is 76.7 per cent, there will be 48,965,280 B.t.u. used to heat, evaporate and superheat the steam. Deducting the amount of heat lost in radiation there will be 46,092,480 B.t.u. in the steam going to the cylinders.

Assuming the feedwater to have a temperature of 60 deg. fahr. and the steam to be at 200 lb. pressure with 200 deg. superheat and the injector to be 100 per cent efficient thermally, about 36,000 lb. of water will be used by the cylinders of this locomotive per hour.

Of the heat going to the cylinders 41,623,680 B.t.u. is discharged up the stack in the exhaust steam. If the steam is exhausted in a dry and saturated state it will then have a pressure of about 5 lb. and a temperature of 228 deg. fahr.

From this brief analysis it is seen that there are 11,461,200 B.t.u. discharged up the stack in the products of combustion, and 41,623,680 B.t.u. in the exhaust steam. The total is 53,084,880 B.t.u. or 83.2 per cent of the total heat of the coal in question.

Necessarily, any part of this heat that is reclaimed and returned to the boiler will allow a reduction by the same amount in the quantity of heat supplied by the coal to produce the same cylinder horsepower.

The most natural and feasible method of collecting part of this waste and again delivering it into the boiler is by using as much of it as is practicable to heat the feedwater before it enters the boiler. All of the heat that can be reclaimed in this way is a net saving.

Two different sources of waste heat are available, viz., exhaust steam and products of combustion or smokebox gases; but because of the size of apparatus and maintenance difficulties in the latter case, it is advisable to absorb all the heat possible from the exhaust steam before attempting to use the hot gases.

A careful study of the experiments that have been made on the heating of water will show that the amount of heat transferred across the unit area will vary greatly with the scouring action of the water as well as the heating medium. In the case of exhaust-steam heaters, however, where it is necessary to condense the heating medium in order to abstract its heat, the problem of a high heat transfer resolves itself largely into obtaining a high rate of agitation of the water. The efficiency of each unit of area will increase as the agitation is increased. Great agitation of the water necessarily implies the employment of energy, and the problem becomes the selection of a suitable form of apparatus which will give the highest rate of agitation of the water with the least cost for power.

One form of apparatus that has been in very successful use and is based on these principles is the Lovekin film heater, which has been applied extensively in marine practice, where the requirements demand minimum size and weight for the greatest efficiency.

In this heater the water is in a thin film between two spirally corrugated copper tubes. See Fig. 1. The heating medium, which is exhaust steam taken from the exhaust passages in the cylinders, is present on the inside of the inner tube and the outside of the outer tube, or on both sides of the water film. The water passing through this tortuous passage acquires a very high rate of agitation, and heat transfers greater than 900 B.t.u. per sq. ft. per hr. per degree average temperature difference are obtainable with a reasonable frictional resistance through the heater.

This design of heater, when arranged for a locomotive using 30,000 lb. of water an hour, forms an apparatus measuring $17\frac{1}{2} \times 21\frac{1}{4}$ in. in section outside and 82 in. in total length. It is easily fitted on the front deck, close to the cylinders, and

under the extension on the front end where it in nowise interferes with any other part of the locomotive and is entirely accessible for inspection or cleaning, if necessary. Fig. 1 shows this heater in section. It has been giving excellent results on a high-speed passenger locomotive during the past seven months, and has shown itself able to heat water from 45 deg. fahr. to 225 deg., or a temperature rise of 180 deg., with an exhaust-steam temperature of 240 deg.

If the conditions assumed for the locomotive above with feedwater temperature of 60 deg. and exhaust-steam temperature of 228 deg. are considered, it will be seen that a temperature rise of 153 deg. can be obtained in the feedwater, or an absorption of 5,508,000 B.t.u., or 13.4 per cent of the heat from the exhaust steam which had previously been wasted. This would be returned to the boiler as a saving from the feedwater heating.

If the feedwater is discharged from the exhaust-steam heater at more than 225 deg., which implies a back pressure of 10 lb. and is as hot as could normally be expected with that temperature of heating medium, there is still a range of 166 deg. that it can be raised before reaching the temperature corresponding to the boiler pressure. This would then have to be done by the exhaust gases, which have a temperature suitable for the purpose, frequently being 700 deg. or more. This would require, in this instance, the absorption of 5,868,000 B.t.u., or about 51 per cent of the heat contained in the exhaust gases.

There are no reliable figures available in regard to the transfer of heat from front-end gases of a locomotive to water on a unit basis, but it is quite probable that with any practical form of apparatus a heat transfer greater than 15 B.t.u. per sq. ft. per hour, per deg. average temperature difference will not be exceeded. If we accept this figure for the purposes of investigation and assume that there will be an average temperature difference between the hot gases and the water of 250 deg., it develops that over 1500 sq. ft. of heating surface will be required to raise the water 163 deg. in temperature. It is evident, therefore, that a form of construction which will give a higher heat transfer per square foot than that assumed will have to be developed and perfected, or it will be necessary to be satisfied with the lower temperature of feedwater.

Another feature of the subject which should not be overlooked is the effect of feedwater heating on the boiler efficiency. As the rate of combustion is decreased, the boiler efficiency increases, and when a feedwater heater is applied to the locomotive it allows the production of the desired amount of steam with a reduction in the amount of coal fired, which increases the boiler efficiency, in turn requiring still less coal to produce the results desired. In this way a very material saving is accomplished in the whole locomotive, which, while not produced by the feedwater heater, results from its application. In the case of a large passenger locomotive a reduction of 10 lb. of coal per sq. ft. of grate area per hour gives an increase in the boiler efficiency of about 3 per cent, which should be credited to the heater.

In order that the maximum amount of heat may be absorbed from the exhaust steam, it is necessary that the water shall enter the heater at the lowest possible temperature, which requires the use of a pump to force the water through the heater in the case of a closed heater similar to the one illustrated, or draw it from the heater in the case of an open type of heater. In the case of the open type of heater, temperatures greater than 212 deg. will not be obtainable, and this fact, in addition to the well-known difficulties that accompany the practice of pumping hot water, make it advisable to place the pump between the water supply and the heater and use the closed-type or pressure heater.

A satisfactory pump for this purpose should not only be reliable, durable and suitable for operating under the highly difficult conditions present on a moving locomotive, and also require an absolute minimum of attention for its maintenance, but it must also give a very high efficiency since the steam it requires for operation is practically a net loss to the locomotive as a whole. It is of course good practice to discharge the exhaust from the feed pump into the heater and there condense it, but the amount of heat taken up from this source reduces the amount that can be absorbed by the feedwater from the exhaust steam of the cylinders, and therefore, so far as economy is concerned, it gives no advantage.

A pump has recently been perfected by the Westinghouse Air Brake Company for use on locomotives which appears to answer the requirements in a very satisfactory manner. It is able to deliver more than 50 lb. of water against a pressure of 240 lb. for each pound of steam, at 150 lb. pressure, and will handle about 65,000 lb. of water per hour as a maximum. The amount of water pumped is controlled by the steam pressure on the pump through the medium of a simple throttle valve located in the cab and operated by the engineer.

A rule of thumb that has long been used in stationary and marine practice is that for each 11 degrees the feedwater is heated by a source otherwise wasted, there will be 1 per cent saving in fuel. Such experiments as have been made on locomotives indicate that this amount is conservative and can be easily attained. When the maximum capacity of the locomotive is being used, savings considerably in excess of this are indicated. It appears that an economy of at least 10 per cent can be reasonably expected even at light rates of working.

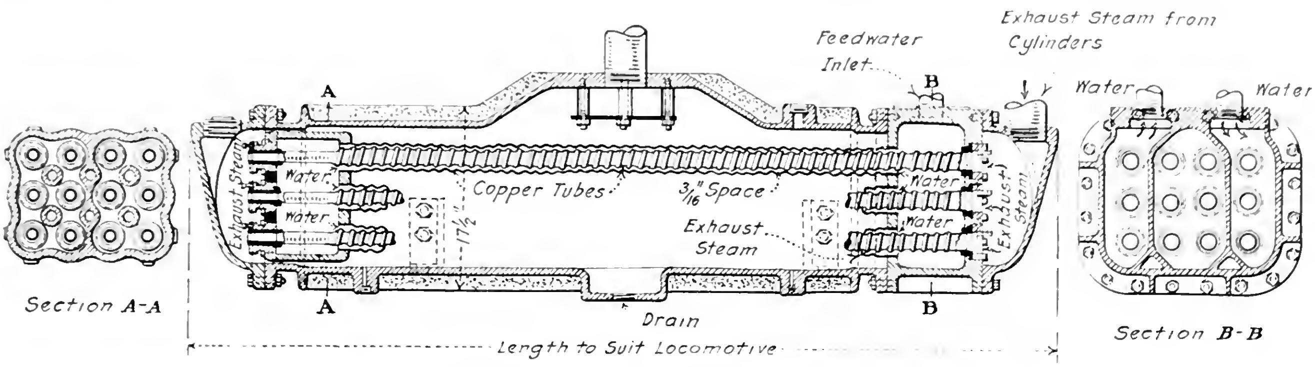

FIG. 1 LOCOMOTIVE FEEDWATER HEATER SHOWN IN SECTION

THE LOCOMOTIVE FIREBOX AND COMBUSTION CHAMBER

By J. T. ANTHONY,[1] NEW YORK, N. Y.

THE growing demands and economic problems confronting the railroads have resulted, among other things, in increased train loads. This has necessitated a large increase in the capacity of motive power units required, which has been obtained by increasing the size of the locomotive and the steaming capacity of its boiler. Since the sustained hauling capacity of a locomotive depends upon the ability of its boiler to deliver steam, and the steam generation depends upon the amount of coal that can be burned and heat liberated, the firebox has been the controlling factor in the successful operation of high-capacity locomotives.

The operating conditions of the future are problematical, but the indications are that in addition to present demands

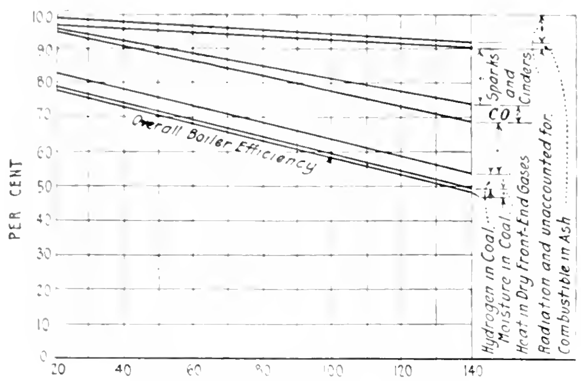

FIG. 1 HEAT LOSS AND BOILER EFFICIENCY AS AFFECTED BY RATE OF COMBUSTION

for high hauling capacity there will be a demand for higher speeds. The average locomotive is in service doing useful work 4 hr. and 17 min. out of each 24 hr., with a daily average of about 75 miles. It is highly probable that strenuous efforts will be made in the future to increase the amount of time the locomotive is engaged in useful work, and to increase the length of the runs and locomotive mileage per day by changing crews when necessary.

If these conditions arise, the controlling factor will be the firebox and its ability to burn the coal properly and liberate the heat required over long periods of time. Regarded from the standpoint of present operating conditions or possible future conditions, the locomotive firebox is a vital factor; and no operating or mechanical official can afford to neglect the study of its present defects or future possibilities.

The firebox has two functions to perform. The first and most important is the burning of the coal and liberation of the heat contained. The second is the absorption of heat by the firebox heating surfaces.

Only a part of the coal burns on the grates. Under normal conditions at least 50 per cent of the heat is liberated by the burning of gases above the fuel bed. Ample air supply, thorough mixing of the gases, and combustion space are necessary for the complete burning of the gases. For efficient firebox performance, combustion chambers and mixing devices are as necessary as the grates.

The firebox furnishes only 5 to 10 per cent of the total heating surface, but is responsible for 25 to 50 per cent of the total evaporation, due to the fact that its heating surfaces are ideally disposed for the absorption of radiant heat. Maximum boiler capacity and efficiency cannot be obtained without providing for the generation and absorption of this radiant heat.

Fig. 1 shows a fair average of boiler efficiency and heat losses on modern locomotives equipped with brick arches and superheaters. It will be noted that the boiler efficiency drops from about 78 per cent down to 48 per cent as the rate of combustion increases from 20 to 140 lb. of coal per sq. ft. of grate per hour. It will also be noted that the greatest heat losses are those due to the heat carried away by the front-end gases and the heat loss in sparks and cinders; the former remaining nearly uniform throughout the range of tests, while the latter increases rapidly as the rate of combustion increases.

It is common practice to design locomotives to deliver their rated tractive effort when burning 120 lb. of coal per sq. ft. of grate per hour. Fig. 2 shows the average heat distribution and losses at this rate of combustion. Fifty-three per cent of the heat contained in the coal is absorbed by the boiler and 47 per cent lost. Of the heat lost, 27 per cent is chargeable to the furnace, 6 per cent to the heating surfaces, and 14 per cent is unavoidably lost in the front-end gases.

A comparison of *D* and *I* in Fig. 2 indicates clearly that the furnace (or firebox) is responsible for four times as much heat

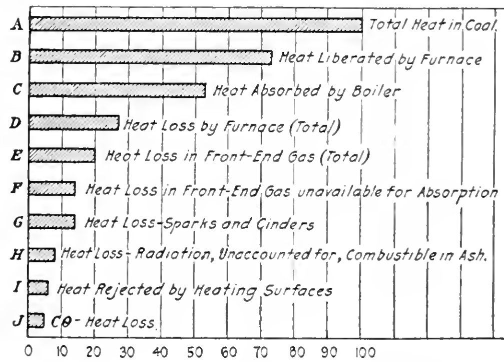

FIG. 2 HEAT DISTRIBUTION AND LOSSES WHEN FIRING COAL AT THE RATE OF 120 LB. PER HOUR PER SQ. FT. OF GRATE

waste as the boiler heating surfaces; and it becomes very evident that the largest field for improvement lies in the locomotive firebox, and not in the heat-absorbing surfaces. This is an all-important fact and one that should be borne in mind: that it profits us little to provide large areas of heating surfaces if proper provisions for burning the coal are not made in the firebox.

FIREBOX LOSSES

Firebox losses consist of:

1 *Combustible in Ash,* due partly to character of coal and to grate design and method of firing. Loss of this nature

---

[1] Assistant to the President, American Arch Company.

Abstract of paper, copyright 1917 by the American Arch Company, presented at a meeting of the Birmingham Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, January 24, 1917.

is generally small, not amounting to more than 1 to 1½ per cent.

2 *Carbon Monoxide.* This gas is unavoidably formed in large quantities in the fuel bed, and must be burned in the combustion-chamber space. Its formation can be reduced by providing grate area sufficient to prevent high rates of combustion and to allow a light fire to be carried, thereby insuring an ample air supply, both in the fuel bed and in the firebox space above. Once formed, the gas can be completely burned only by *mixing* with an excess of oxygen and providing ample combustion-chamber space.

3 *Unburned Hydrocarbons*, which account for a large part of the so-called "unaccounted-for" losses. These gases are distilled off from the green coal and burn above the fuel bed. To burn them completely it is necessary to provide an excess of oxygen above the fuel bed, to mix thoroughly, and to have a large combustion chamber and long flameway. Even with these provisions it is very difficult to burn some of the heavy hydrocarbons, which are driven off in the form of tarry vapors.

4 *Sparks and Cinders* are responsible for the largest heat loss at high rates of combustion. This loss can be greatly reduced by increasing the grate area and reducing the velocity of the draft through the fuel bed. Refractory baffles to break up and deflect the cinders, and combustion chambers of ample volume and length wherein the fine particles can burn, will cause a further reduction in these losses.

Summed up, the elimination or reduction of the firebox losses can be brought about by increasing the grate area, firebox volume and combustion-chamber space by providing effectual baffles and mixing devices, and supplying at least 33 per cent excess air, or approximately 16 lb. of air per lb. of coal.

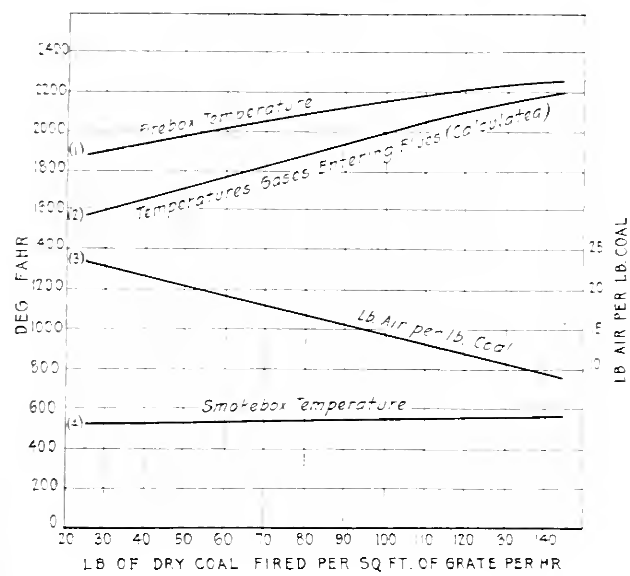

FIG. 3 CHART SHOWING EFFECT OF RATE OF COMBUSTION ON FIREBOX AND SMOKEBOX TEMPERATURES, TEMPERATURE OF GASES ENTERING FLUES, AND AIR SUPPLY PER POUND OF COAL

Air sufficient for complete combustion can be drawn into the firebox at low and moderate rates of combustion if sufficient openings are provided in ashpans and grates. At high rates of combustion it is impossible to get enough air into the firebox to complete combustion, and this is always found to be the controlling factor when driving locomotives to their maximum capacity.

COMBUSTION CHAMBERS

Ordinarily, we are apt to think of coal as burning on the grates, when as a matter of fact a large part of the coal burns above the fuel bed in the form of gas. Consider the case of the large boiler, such as is used on the Pacific- and Mikado-type engines, with 70 sq. ft. of grate, 311 cu. ft. of firebox volume, 232 sq. ft. of firebox heating surface and 5280 sq. ft. of flue and superheating surface, the firebox being without a combustion chamber and equipped with a brick arch. The coal used was high-volatile Westmoreland with a heat value of 14,430 B.t.u. per lb. and having the following composition:

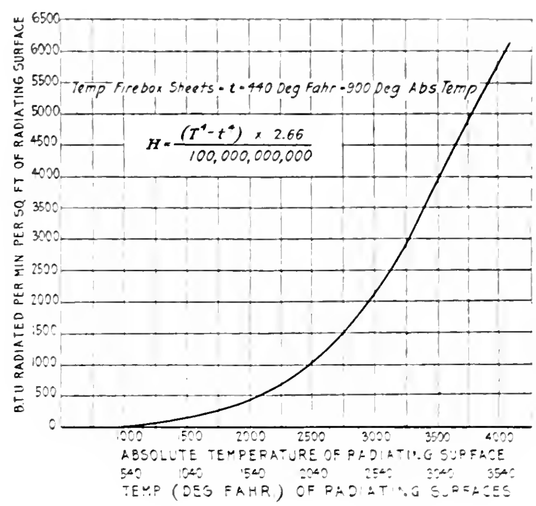

FIG. 4 AMOUNT OF HEAT RADIATED PER MINUTE PER SQUARE FOOT OF RADIATING SURFACE WHEN TEMPERATURE OF FIRE SIDE OF FIREBOX SHEETS IS 440 DEG. FAHR.

	Per cent		Per cent
Fixed carbon.......	57	Carbon	78
Volatile matter.....	35	Hydrogen	5¾
Moisture	1	Nitrogen	1½
Ash	7	Sulphur	1½
	—	Ash	7
	100	Oxygen	6¼
			—
			100

At a rate of combustion of 120 lb. of coal per square ft. of grate per hour, 8400 lb. was fired (which is equivalent to 140 lb. per min., or 2.33 lb. per sec.). The coal contained 57 per cent of fixed carbon; and if all this burned on the grate, there would be liberated 8350 heat units—or 58 per cent of the heat contained in the coal—while 6080 heat units (or 42 per cent) would be liberated by the volatile combustible burning above the fuel bed.

However, all of the fixed carbon does not burn on the grate. The oxygen, on coming in contact with the glowing coals next to the grate, combines with the carbon to form carbon dioxide, and this, passing up through the fuel bed, comes in contact with other glowing coals and is reduced to carbon monoxide; and there is a large percentage of the latter gas mixed with the carbon dioxide and other gases arising from the fuel bed.

Tests indicate that often there is as much as 80 per cent of the fixed carbon incompletely burned to carbon monoxide,

and in order to avoid a large heat loss, this carbon monoxide must be mixed with sufficient oxygen to enable it to be completely burned in the combustion chamber space above the fuel bed.

Assume, for example, that 50 per cent of the fixed carbon is completely burned on the grates and 50 per cent is incompletely burned to carbon monoxide. The gases arising from the fuel bed will have the composition, weight and volume shown in Table 1.

TABLE 1 COMPOSITION AND VOLUME OF GASES IN FIREBOX

WHEN BURNING 120 LB. OF COAL PER SQUARE FOOT OF GRATE PER HOUR, WITH AN AIR SUPPLY OF $12\frac{3}{4}$ LB., AND ONE-HALF OF FIXED CARBON COMPLETELY BURNED ON THE GRATES. FIREBOX TEMPERATURE = 2200 DEG. FAHR.

Gas	Symbol	Arising from Fuel Bed			Combustion Completed	
		Lb. per Sec.	Cu. Ft. per Sec.	Per Cent Vol.	Cu. Ft. per Sec.	Per Cent Vol.
Ethane [1]	C_2H_6	0.50	38	1.87	0	0

[1] Ethane assumed to represent average composition of the hydrocarbons.

Under these conditions, only 40 per cent of the heat contained in the coal would be liberated on the grate, while 60

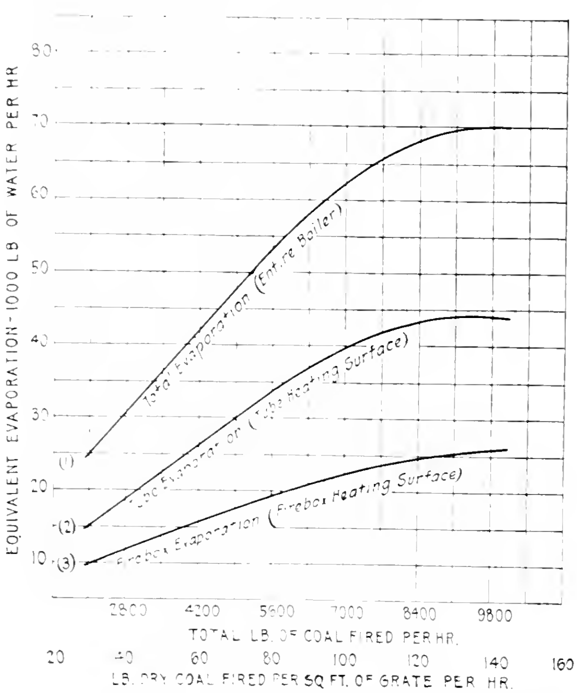

FIG. 5 EQUIVALENT EVAPORATION PER HOUR FOR VARIOUS RATES OF FIRING

per cent would be liberated by the burning of the gases in the combustion-chamber space.

We have assumed that the combustion in the firebox is complete and that there is no hydrocarbon or carbon monoxide contained in the gases entering the flues, as shown by the right-hand column of the table. Under the conditions, however, perfect combustion could not be obtained, as the air supply, $12\frac{3}{4}$ lb. per pound of coal, is insufficient. Table 1 shows that there is an excess of 2.75 per cent free oxygen in the final products of combustion; but this is not sufficient to guarantee complete combustion, on account of the presence of the large volumes of inert gases, which interfere with the mixing of the oxygen with the combustibles; and also on account of the short time available for combustion of each particle of gas.

The velocity with which the combustible gases burn depends upon the volume percentages of the combustible and the oxygen present. For instance, with the gases arising from the fuel bed containing 5 per cent carbon monoxide and 12 per cent oxygen, the velocity of combustion would be proportional to $5^2 \times 12 = 300$.

Where combustion is nearly complete and the gases contain, say, 1 per cent carbon monoxide and 3 per cent oxygen, the velocity of combustion would be proportional to $1^2 \times 3 = 3$; or it would be 100 times more rapid in the first than in the second case. This slowness of combustion can be partially offset by providing long flameway and combustion-chamber space; but in addition combustion must be speeded up by increasing the supply of oxygen if perfect combustion is to be obtained.

As shown, the total volume of gases evolved per second is more than 2000 cu. ft. The firebox has a volume of 311 cu. ft., which means that the firebox is being filled and refilled with gases about six and one-half times per second; or that the time available for the combustion of each particle of gas will average less than one-sixth of a second.

It is evident from the above that it is a very difficult matter to burn completely the combustible gases in an ordinary firebox, although, as a rule, front-end-gas analyses fail to account for these losses. This is due to our method of making these analyses, no provision being made ordinarily to detect the presence of unburned hydrocarbons; while the presence of a small percentage of carbon monoxide may often pass undetected, owing to methods employed in collecting gas samples and to chances for error in gas analyses.

The presence of 0.1 per cent of unburned hydrocarbon in the front-end gas under the above conditions would indicate a loss of more than 2 per cent of the entire heat contained in the coal; and such losses, and much larger losses, are constantly occurring.

The large volume of gases evolved and the amount of heat generated by the burning of these gases emphasize the importance of firebox volume and combustion-chamber space. The fuel bed is little more than a gas producer, and adequate provisions must be made for burning these gases if perfect combustion is to be approximated.

FIREBOX HEATING SURFACE

Fig. 3 shows the firebox and smokebox temperatures and air supply per pound of coal, obtained in tests of the locomotive under consideration. It will be noted that as the rate of combustion increased from 30 to 140 lb. of coal, the firebox temperature rose from 1900 to 2240 deg. fahr., while the smokebox temperature increased from 520 to 580 deg. At the same time the air supply per pound of coal decreased from $22\frac{1}{2}$ to 10 lb. The firebox temperature shown is probably higher than that generally obtained in road service; but high

firebox temperatures are much to be desired, as the evaporation increases rapidly with the rise in temperature.

Firebox heating surfaces receive practically all of their heat by radiation, the heat being radiated directly from the luminous fuel bed, flames and brickwork, traveling from these radiating surfaces by "rays" to the firebox heating surfaces.

The locomotive firebox is ideally suited to the absorption of radiant heat, having the radiating bodies, such as the fuel bed and flames, surrounded by the cooler, soot-covered heating surfaces, which absorb all the radiant heat and reflect none of it away.

The curve in Fig. 4 shows the amount of heat radiated per minute per square foot of radiating surface for various firebox temperatures when the temperature of a firebox sheet on the fire side is 440 deg. fahr. The points determining the curve were figured from the formula (Stefan-Boltzmann) shown, absolute temperatures being used. With a firebox temperature of 1540 deg., each square foot of radiating surface gives off about 400 heat units; whereas, if the temperature is increased to 2040 deg., more than 1000 heat units are radiated per minute; while a temperature of 3000 deg. would give a radiation of almost 4000 heat units per minute per square foot of radiating surface.

High firebox temperatures are necessary if high firebox evaporation is to be obtained; but temperature is but one of the two controlling factors, the other being the area or extent of the radiating surfaces. The fuel bed is a radiating body, and the area of the radiating surface of the fuel bed is readily determined. Flames also radiate heat, but the amount of flame in a firebox is very variable and the amount of heat radiated therefrom is difficult to determine. If the firebox is completely filled with a mass of flame, the effective flame-radiating surfaces will be equal to the exposed firebox heating surfaces. If the firebox is not completely filled with flame, the flame-radiating surfaces will be less.

Assuming that the firebox was completely filled with flame when burning the high-volatile coal at a rate of 80 lb. per square foot of grate per hour and was 50 per cent filled at the low rates of combustion. Curve 3 in Fig. 5 was plotted, the flame temperature being assumed to equal that of the firebox. The curve showing the total equivalent evaporation from the boiler was plotted from actual test data. The curve of firebox evaporation was calculated from the curve in Fig. 4, using the firebox temperatures shown in Fig. 3. The curve showing tube evaporation was obtained by subtracting the firebox evaporation from the total.

At the lowest rate of evaporation the curve indicates that the firebox evaporated 40 per cent of the total, and at the highest rate, 37 per cent. An equivalent evaporation of 26,000 lb. per hour from 230 sq. ft. of heating surface means an evaporation of 105.6 lb. per hour per sq. ft. of heating surface. In order to get such an evaporation, each square foot of heating surface would have to transfer 102,400 heat units per hour, and the temperature on the fire side of the sheet would be about 536 deg. if the sheets were clean. These figures will serve to show what can be expected when high firebox temperatures and large radiating surfaces are to be had; for firebox evaporation depends principally upon these two factors, and only indirectly upon the extent of the firebox heating surfaces.

Increasing the firebox heating surfaces by the addition of a combustion chamber increases the firebox evaporation only to the extent that the combustion chamber is filled with flame or heat-radiating surfaces. If the combustion chamber is not filled with flame, there will be practically no increase in firebox evaporation; for the combustion-chamber heating surface is so arranged that it can take up but an inappreciable amount of heat from the gases by convection.

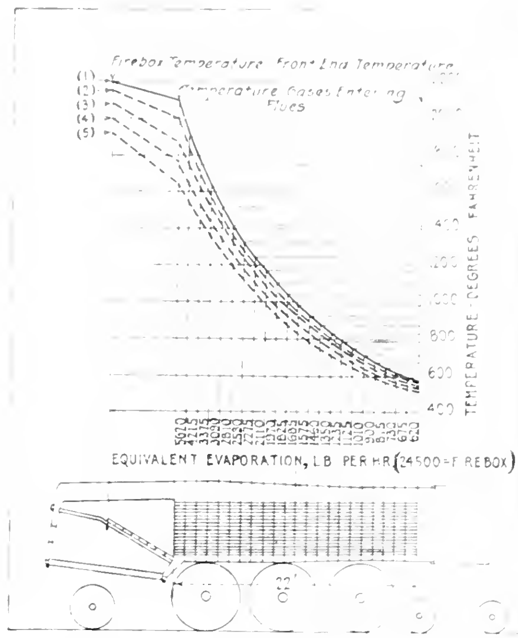

FIG 6. TEMPERATURE DROP FROM FIREBOX TO FRONT END AT VARIOUS RATES OF COMBUSTION

(1), 120 lb. per sq. ft. of grate per hour; (2), 100 lb.; (3), 80 lb.; (4), 60 lb.; (5), 40 lb. Evaporation for each 1-ft. section of tubes calculated from temperature drop shown by Curve (1)

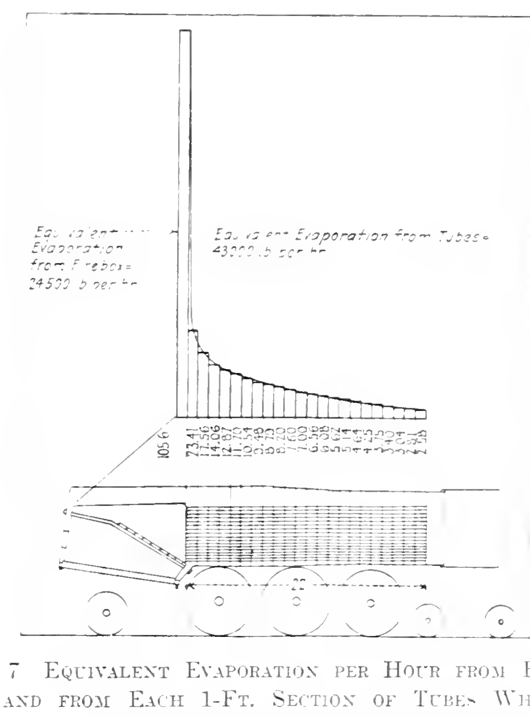

FIG. 7 EQUIVALENT EVAPORATION PER HOUR FROM FIREBOX AND FROM EACH 1-FT. SECTION OF TUBES WHEN BURNING 120 LB. COAL PER SQ. FT. OF GRATE PER HOUR

Figures show equivalent evaporation per sq. ft. of heating surface per hour. Grate area, 70 sq. ft; firebox heating surface, 232 sq. ft.; tube-heating surface, 5280 sq. ft. = 240 sq. ft. per 1-ft. section.

The curves in Fig. 6 show the characteristic drops in temperature of the gases in passing through the flues when burn-

ing coal at varying rates per square foot of grate per hour, with the air supply shown in Fig. 3

Suppose the flues to have been divided into 22 equal sections, each 1 ft. in length and containing 240 sq. ft. of heating surface. With a constant weight of gases passing through, the drop in temperature through each 1 ft. section becomes a measure of the evaporation in that section; and the figures per square foot of flue heating surface would be 8.14 lb. per hour, this evaporation ranging from 23.4 lb. in the section next to the firebox down to 2.58 lb. per sq. ft. in the section adjacent to the front flue sheet. It will be noted that the first four sections from the front end have a total equivalent evaporation of only 2840 lb. per hour, or about half that produced by the one section adjacent to the back flue sheet.

Fig. 8 Ordinary Firebox without Baffle or Other Gas-Mixing Device

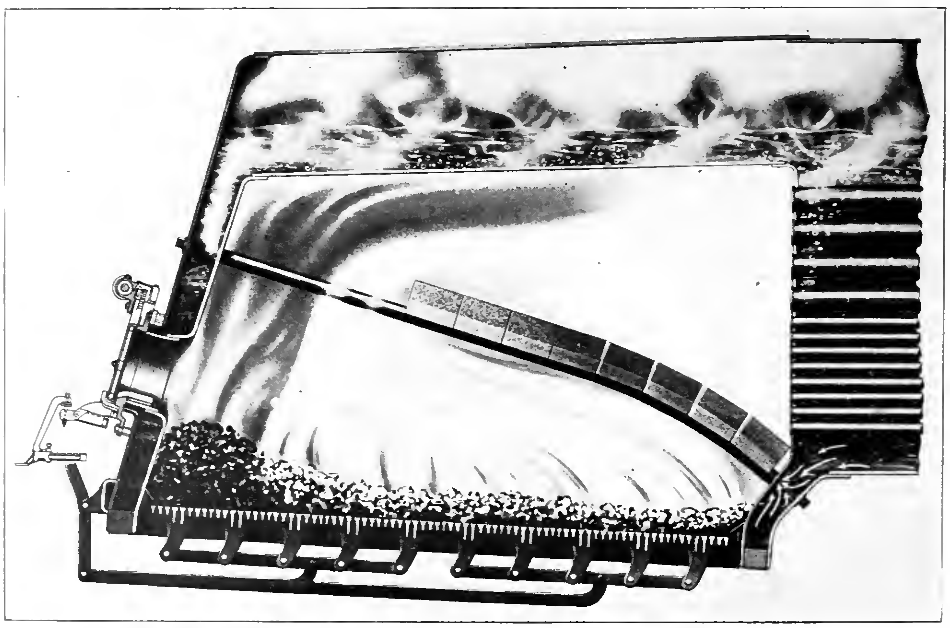

Fig. 9 Ordinary Type of Firebox Equipped with an Arch

showing the total equivalent evaporation from each section and the equivalent evaporation per square foot of heating surface were calculated from the temperature drops and the weight of the gases, assuming the specific heat to be constant throughout. This assumption introduces a small error into the calculations, but it is not sufficient to affect the results greatly.

With an equivalent evaporation per square foot of firebox heating surface of 105.6 lb. per hour, the average evaporation

A reduction of the flue lengths to, say, 18 ft. by the application of a 4-ft. combustion chamber would reduce the flue heating surface 960 sq. ft., increase the firebox surface by 76 sq. ft., and add 108 cu. ft. to the firebox volume. What effect would such a change have upon the boiler evaporation and efficiency?

As shown in Fig. 2, more than 25 per cent of the heat contained in the coal is lost through imperfect combustion. If

the additional firebox volume obtained by the use of the combustion chamber effected a saving of one-fourth of this heat loss, the resulting combustion would cause an increase in firebox evaporation of approximately 8025 lb. to offset the 2840 lb. lost by shortening the flues.

Boiler tests show even larger increases in efficiency brought about by the introduction of the combustion chamber; and a study of the questions of furnace losses and heat generation by the burning gases will make it clear why the application of a combustion chamber to a locomotive does increase fire-

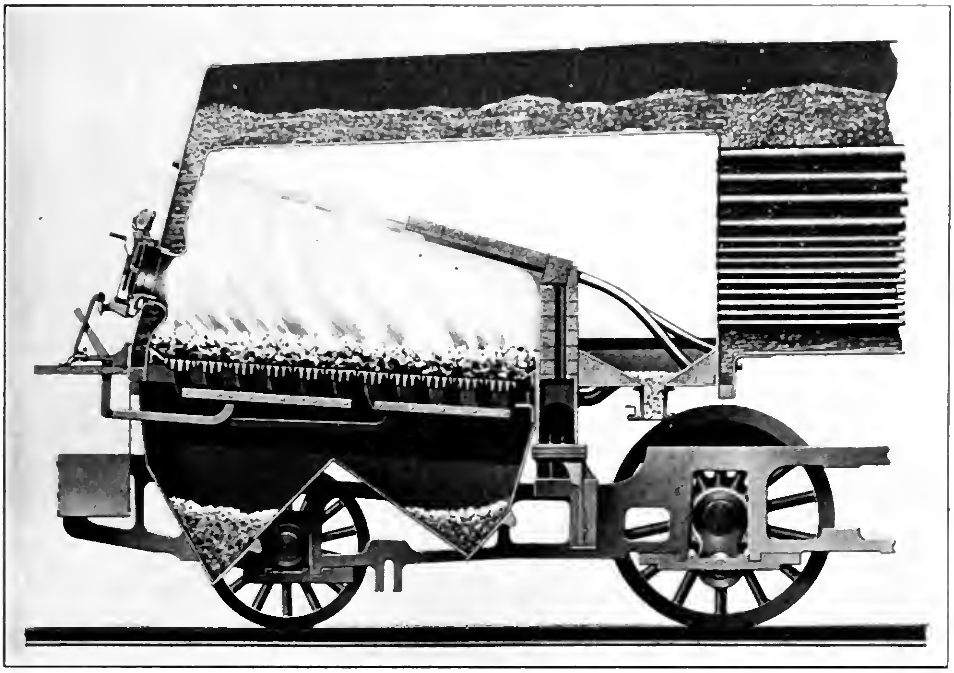

Fig. 10 Firebox Equipped with the Gaines Locomotive Furnace

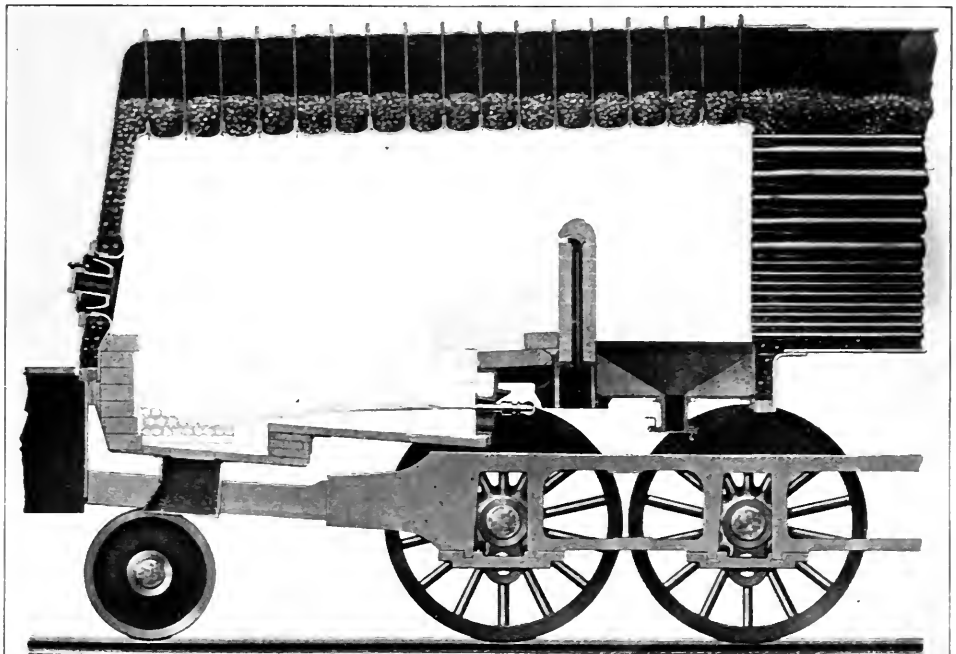

Fig. 11 Straight-Wall Type of Gaines Combustion Chamber as Applied to an Oil-Burning Locomotive of the 2-10-2 Type

This increased firebox evaporation would be obtained by the generation of heat that would otherwise have been lost, and there would be little or no reduction in the temperature of gases entering the flues. The front-end temperature would be increased, but there would be a net increase of $7\frac{1}{2}$ per cent in boiler efficiency, due to the combustion chamber.

box evaporation and decreases the heat losses caused by the escape of unburned volatile combustibles and fine particles of coal.

While comparatively few reliable tests have been made for the purpose of determining the effect of a combustion-chamber installation upon boiler efficiency, the three shown in Table 2

give a clear indication of the value of firebox volume and combustion chamber space.

TABLE 2

Locomotive Type	Cylinder Size	Fuel Used	Relative Boiler Efficiency, Per Cent.	
			With Gaines Combustion Chamber	Without
[illegible]	[illegible]	Coal	100	62
[illegible]	[illegible]	Coal	100	78
2-10-2	[illegible]	Oil	100	80

The variation in boiler efficiencies in the table is due partly to the character of the fuel and partly to the difference in lengths of combustion chambers and peculiarities of firebox design.

The relative efficiency of the firebox heating surfaces as compared with the flue heating surfaces is shown by the curve in Fig. 7. The base of the rectangle represents the heating surface, 240 sq. ft. for each section of the flues and 232 sq. ft. for the firebox. The height of the rectangle indicates equivalent evaporation per square foot of heating surface per hour from each of the flue sections, while the area of each rectangle represents the total evaporation per hour.

The principal function of the firebox is to burn coal and liberate the heat; but the amount of water evaporated by the firebox heating surfaces, as shown by the chart, is quite considerable, and full advantage should be taken of the opportunities offered for producing and absorbing radiant heat. Whether considered as a furnace or as a part of the boiler evaporating surface, the firebox is the chief factor in successful boiler performance, on which depends successful locomotive operation.

The value of baffling and gas-mixing devices, firebox volume and combustion-chamber space is becoming more generally recognized, although the engines with long wheelbases and boilers now in vogue present opportunities for combustion-chamber installations of which full advantage is not being taken by many of the American railroads. The advance that has been made along these lines during the past few years is shown by the following illustrations.

Fig. 8 shows the ordinary firebox without a baffle or gas-mixing device of any description. The picture shows clearly the disadvantages of such a firebox and the possibilities of large heat losses due to the escape of unburned hydrocarbon gases distilled off from the bank of green coal under the door, and to the heat loss and flue trouble occasioned by the inrush of cold air through a possible hole in the fire.

Fig. 9 shows the same type of firebox equipped with an arch, and illustrates the advantages of the baffling and mixing obtained by the arch, as well as the protection afforded the flues.

Fig. 10 shows a firebox equipped with the Gaines locomotive furnace, in which the flue sheet is carried forward to a point directly over the rear driver, the mudrings being upset at the sides to provide sufficient clearance.

Fig. 11 shows a straight-wall type of Gaines combustion chamber, as applied to an oil-burning locomotive of the 2-10-2 type. This is the first installation of its kind that has been made on road engines.

These latter illustrations show the furnace layouts of locomotives that are in actual operation; and the results obtained in fuel economy, boiler capacity and low cost of maintenance give additional weight to the arguments advanced regarding the effect of heat radiation from fuel bed, flameways and brickwork, and the necessity of large firebox volume and long flameway.

Rhotanium—A Platinum Substitute

Rhotanium, a palladium-gold alloy in which the gold content varies from 60 to 90 per cent, is said to form a satisfactory substitute for platinum. It is malleable and ductile and can be welded without the use of a flux or other reagent. Its specific gravity ranges from about 16 to 18.5, according to composition, and its losses by volatilization at temperatures below 1300 deg. cent. are less than those of commercial platinum. It can be used, within its temperature limitations, in electric heating units, and is satisfactory for contact terminals in many forms of automatic electric devices. Its behavior when tested on certain magnetos was satisfactory, but experiments performed on a high-grade aeroplane-engine magneto gave negative results. It is not suitable for use with hot concentrated nitric acid nor for electrolytic anodes, but for all other chemical purposes it is entirely satisfactory if the proper composition is chosen and if properly manufactured. Certain of the alloys have given good service in dentistry when used for pins and baked into porcelain teeth and as thin foil and heavy sheet for other types of construction. Rhotanium is said to be superior to pure platinum for use in jewelry; it is harder, stronger, and takes a better finish. It does not tarnish, is non-corrodible, has practically the color of platinum, and can be worked as readily. Jewelry made with it passes the common jewelers' and platinum buyers' tests. (U. S. Commerce Reports, abstracted in *Machinery,* vol. 23, no. 12, August 1917, p. 1096)

Patent Merger in Aircraft

According to statements in the press, the manufacturers of aircraft have formed an organization under the name of Manufacturers' Aircraft Association. The most important feature of this association is an agreement entered into by the manufacturers composing it, with a view to cross-licensing the various patents held by the members.

According to a statement given out by the chairman of the publicity committee of the association, it is proposed that each member should pay a royalty of $200 on each machine built by him. Of this sum $135 will be paid to the Wright interests and $40 to the Curtiss interests until the Wright interests have accumulated $2,000,000. Thereafter $175 will go to the Curtiss interests until they have accumulated a similar sum. The residue of $25 on each machine is to go to the general fund of the association.

By the terms of the cross-licensing agreement any responsible manufacturer of aircraft, or one who intends to become a bona-fide producer of same, or any manufacturer to whom the United States Government has given a contract for the construction of ten or more aeroplanes, or any person, firm, or corporation owning or controlling United States patents relating to aeroplanes, may become a party to the agreement and can qualify as a member.

Under the terms of this agreement all patent litigation relating to aeroplanes between members of the association ceases automatically. From the text of the announcement and statements made by the officers, it appears that the agreement covers the aeroplane proper, but not the engine.

The office of the association is at 501 Fifth Ave., New York City. Frank H. Russell, of the Burgess Company, is president of the association, and Benjamin S. Foss, of the Sturtevant Aeroplane Company, is secretary.

THE POPPET-VALVE STEAM ENGINE

With Special Reference to the Present Status of the Poppet-Valve Uniflow, Semi-Uniflow and Return-Flow Steam Engine in the United States

By SIEGFRIED ROSENZWEIG, NEW YORK, N. Y.

Member of the Society

It was in the sixties of the last century that the first poppet-valve engine appeared on the market. It was designed by a young Englishman, Charles Brown, chief engineer of the famous firm of Sulzer Bros., of Winterthur, Switzerland.

This first Sulzer engine became, and still is, the standard design of modern poppet-valve engines. The engine has the side shaft driven from the main shaft by a pair of bevel gears; the two admission valves are mounted on the top, and the two exhaust valves placed at the bottom of the cylinder; and mounted on the side shaft are the four eccentrics, straps and rods for the operation of the valve mechanism. The whole arrangement is excellent and possesses many fine points, the consequence of thoughtful and careful design and workmanship.

While the Corliss engine was finding great favor in this country, and also in England and France, engineers in Germany, Austria and Switzerland pinned their faith to the poppet-valve engine, being convinced that, with the advent of higher steam pressures and higher steam temperatures in general, the poppet valve was more suitable for steam distribution than any other kind of valve. Present-day practice demonstrates that these engineers displayed sound judgment.

It is hardly necessary to enter into the subject of high steam pressures and superheat, but a few figures might be of interest. By increasing the steam pressure, the capacity of the engine is correspondingly increased while the additional heat expenditure is very small. For instance, steam at 100 lb. gage contains 1191 B.t.u. per lb.: at 200 lb. 9 B.t.u. more, and at 500 lb. 19 B.t.u. more, showing that the additional heat required for raising the steam pressure is insignificant.

In this respect the following statement may be quoted from a paper read by Robert Cramer on Higher Steam Pressures[1]: "It is apparent that high steam pressures will permit neither slide nor Corliss valves. The advent of higher pressure will cause the poppet valve to come into its own in America, where it is now seldom used, in spite of the great success it has had in Europe for many years, lately the flexible-seat type especially."

The advantages of the poppet valve are:

1 No rubbing surfaces, hence no lubrication, and its adaptability for high temperatures
2 Small weight and practical balance, hence its adaptability for high speed and high steam pressure
3 No possible wear, consequently the engine economy maintained for an indefinite period.

The comparison shown in Fig. 1 is taken from actual designs. The two valves have the same free area, 65 sq. in., while the weight of the four poppet valves is 72 lb. as against 824 lb. for the four Corliss valves.

In order to combine the advantages and disadvantages of simple and compound engines, the idea of passing the steam through the cylinder in a unidirectional flow, known for more than thirty years, was revived and successfully carried out in practice. Professor Stumpf, of Berlin, Germany, deserves the credit of having designed the first modern and practical uniflow engine.

In these engines the steam enters through admission valves at one end of the cylinder, follows the piston during the expansion period, and escapes through exhaust ports arranged in the center of the cylinder and controlled by the piston.

The steam has a tendency to travel always in the same direction in a unidirectional flow engine, as the rarefication of the steam in the cylinder will take place in a direction toward the central exhaust, cooling the cylinder walls next to the exhaust belt more than those at the other end, and causing a gradual decrease of the temperature of the cylinder walls from the hot cylinder cover to the cool exhaust port, corresponding approximately with the temperature of the expanding steam. The considerable losses caused by the cooling action of the cylinder walls during the admission period, and by reevaporation of steam during the exhaust period in ordinary steam engines, are thus almost entirely avoided.

It seems perfectly feasible that a stratification of the steam, with the wettest particles next to the piston, takes place during the expansion period, but it is doubtful whether, as claimed by Professor Stumpf, it can be maintained during exhaust in view of the rather violent action of the steam in the cylinder when the terminal pressure is suddenly reduced to the back pressure.

While it is true that the cylinder cover remains comparatively unaffected by the flow of steam, it has to be admitted that the piston surface is exposed to the action of the steam. However, on account of the circumferentially arranged exhaust ports, the pressure energy is converted into velocity energy within the exhaust ports to a great extent, without cooling the surface of the piston considerably.

When the exhaust port opens, all the moisture accumulated during the expansion period is completely removed and the possibility of water hammer eliminated.

Further advantages of the uniflow cylinder are due to the fact that the clearance surfaces and volume are considerably reduced as exhaust valves of the usual type are eliminated. The exhaust belt provides an exhaust area considerably in excess of that found in ordinary engines, thus making impossible the pressure difference so often encountered between cylinder and exhaust pipe.

Steam leakage through the exhaust port is rendered practically impossible, as the long piston separates it from the admission valves when the steam pressure is high.

It is evident that the unidirectional flow of steam reduces considerably one of the greatest losses encountered in the ordinary or return-flow engine, namely, the cooling of clearance surfaces, and hence initial condensation. The transformation of energy into power can be effected very economically in

Presented at a meeting of the New York Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS., May 8, 1917.

[1] Trans. Am. Soc. M.E., vol. 37, p. 597.

one cylinder without the necessity of employing compound and triple expansion engines as heretofore.

The advantages of the uniflow engines are:

1. Steam enters at one cylinder end and exhausts at the other end, leaving the hot end hot and the cold end cold, and avoiding clearance losses.
2. The exhaust valves with their large clearance surfaces and volumes are eliminated.
3. Large central exhaust ports are provided which are of about three times the area of those in standard engines.

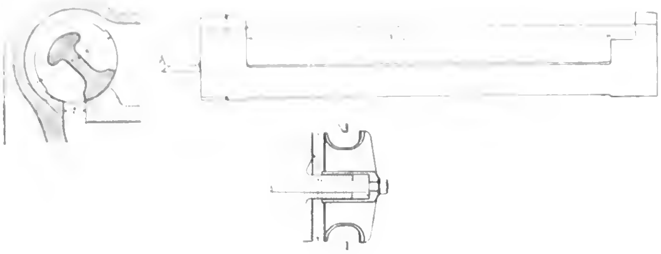

Fig. 1 Comparison of Corliss and Poppet Valves

Free area of Corliss valve	65 sq. in.
Weight of four valves	824 lb.
Free area of Poppet valve	65 sq. in.
Weight of four valves	72 lb.

4. Leakage past exhaust valves and piston is eliminated.
5. Flat steam-consumption curves are obtained for all loads above and below normal.

Comparative steam consumptions of Corliss, poppet-valve and uniflow poppet-valve engines are given in Fig. 2. Noteworthy is the good economy of poppet-valve engines, especially of the uniflow type, at the smaller loads.

An interesting comparison is afforded by the guaranteed steam consumptions of small turbines and uniflow engines for the new three-million-dollar pumping station of the city of Cleveland, Ohio, showing distinctly the great superiority of uniflow engines over turbines, running condensing and non-condensing.

The equipment consisted of an engine driving a 100-kw. generator at 80 per cent power factor. The steam conditions specified were: 200 lb. gage, 100 deg. fahr. superheat, 2 lb. gage back pressure, when running non-condensing, and a vacuum of 26 in. for the engine, 28 in. for the turbine, when operating condensing.

L. A. Quayle, Mechanical Engineer of the Cleveland Water Department, describing the performance of these engines in *Power*, June 6, 1916, says:

> The prices and economy guarantees received on bids from two engine and three turbine builders, as well as informal bids received from two other companies, one a turbine and the other one an engine builder, have been used in making the comparison given here. The prices and guarantee curves represent only the average of three makes of engines and four makes of turbines, including three different makes of generators, all of the bidders being well known.
>
> It is felt that the economy guarantees are conservative, as there was a penalty of $7 per pound of steam per kw-hr. for failure to meet the guaranteed economy, and no bonus was offered for exceeding the guarantees.

STATIONARY ENGINES

Careful experiments carried out by the best authorities during the last few years, on compound and single-cylinder engines of the return-flow and uniflow type, have clearly indicated to the designers of steam engines the principles to be observed in order to obtain highest economies with the simplest mechanical means.

It is essential that, for the sake of economy, clearance in volume and surface be reduced to the lowest possible minimum. In order to obtain the desired results, designers have not hesitated to adopt complicated cylinder and valve-cage designs. Simplicity and accessibility of cylinder and valve-gear parts were sacrificed to economy. A description of the different types of engines will show how an excellent cylinder design can be obtained while employing simple and mechanical means.

The question of valve gear to be used is also of great importance. Complicated mechanisms and trip gears are undesirable, as with them quiet and reliable operation without undue wear is impossible at high speeds. The modern type of steam engine with its steadily increasing rotative speed demands a valve gear of absolutely positive and noiseless operation.

Trip gears are particularly undesirable with poppet-valve engines, as the valve is brought to a sudden stop by coming in contact with the valve seats; such a gear should therefore not be used on engines operating above 100 revolutions.

In order to overcome the disadvantages of the trip valve

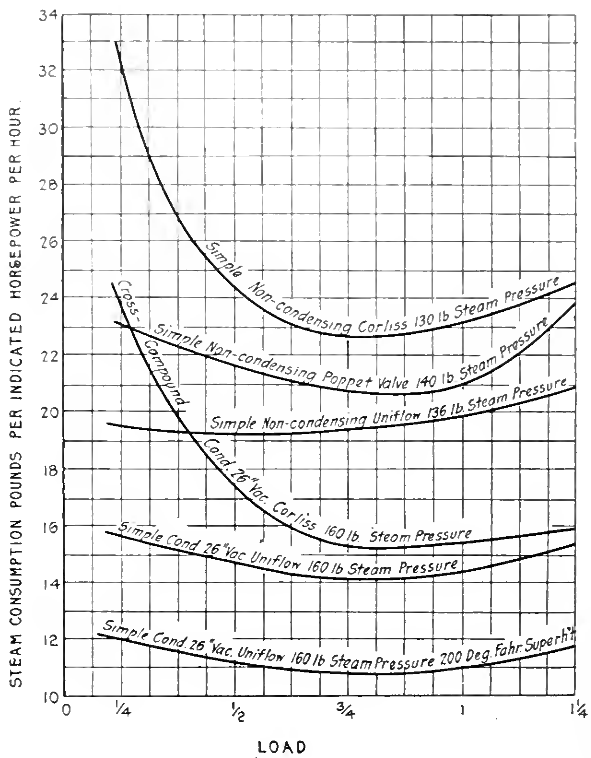

Fig. 2 Comparison of Engine Performances

gears, designs were adopted by means of which the valve was guided back to its seat without being released, avoiding the sudden impact between the metallic surfaces. These so-called positive valve gears were mostly of rather complicated nature and hence were not applicable to high rotative speeds.

The designs of Lentz which were introduced in 1900 and which in this country are manufactured by the Erie City Iron Works, of Erie, Pa., made possible the modern development of the poppet-valve engine. Cam motions such as employed first by Lentz were considered unsafe, as it was feared that the line contact which exists between roller and cam would produce excessive pressures and cause wear on the cam.

The practically universal adaptation of the cam motion for valve gears shows that no wear occurs when the valve-gear working parts are properly designed, made of steel and case-hardened.

Fig. 3 shows the valve gear as used on engines made from the author's designs and as built by the York Mfg. Co., of York, Pa.

In practically 90 per cent of the valve gears for poppet-valve engines, the closing of the valve is partly effected by means of a spring, which is of such strength as to produce not only the retardation forces during the opening but also the acceleration forces necessary during the closing period to keep roller and cam in contact.

A few designers have adopted a double-cam construction, one cam for opening and one for closing the valve, and the spring can thus be omitted. As not only the opening but also the closing is always positively effected by the external valve gear, a short and stiff spring has to be interposed between valve spindle and valve proper to avoid breakage in case foreign matter accumulates on the valve seats. Such valve gear is used by the Nordberg Mfg. Co., Milwaukee, Wis., from the designs of Prof. Doerffel.

All the valve gears mentioned are operated by eccentrics mounted on a lay shaft. It is obvious that the eccentrics may be arranged on the main shaft instead and the valves operated by oscillating levers of the type shown, or by reciprocating camshafts. This arrangement, however, is not as recommendable as the lay-shaft drive except on small engines, as the valve gear is affected by the expansion of the cylinder making resetting under operation conditions necessary. The long eccentric rods and their influence on the regulation are features to be avoided if possible, especially when high speeds are employed.

In several cases the regular Corliss valve gear has been used to operate the poppet valves as adopted in the designs of the Frick Co., Waynesboro, Pa., and in those of the Vilter Mfg. Co., of Milwaukee, Wis.

The high-pressure cylinders of the 6000-hp. engines built by The Hooven, Owens, Rentschler Co., of Hamilton, Ohio, and installed at the plant of the Ford Motor Co., of Detroit, are equipped with poppet valves and the regular Hamilton Corliss gear.

As previously mentioned, trip gears are not recommendable for poppet-valve engines operating at speeds exceeding 100 r.p.m.

As the designs of the author for poppet-valve engines of the return-flow and uniflow poppet-valve type are to a certain extent departures from any other engine of similar type, and as most other designs have been repeatedly described in publications, a more complete description of this engine may not be out of place.

The valve gear of the standard poppet-valve engine is operated by a lay shaft running alongside the engine and driven from the main shaft through a drag crank and shaft by means of a pair of spiral gears. See Fig. 3. The drag crank is self-adjustable and prevents unavoidable motion and jars of the main shaft being transferred to the gears, which for this reason run perfectly noiseless, and are not subjected to any undue wear.

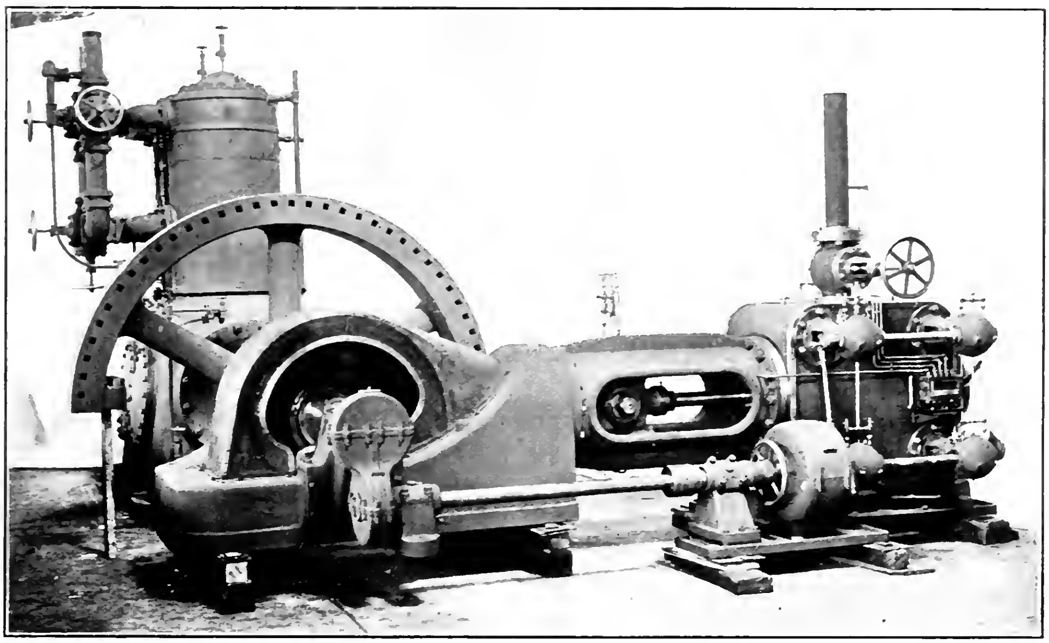

Fig. 3 Poppet-Valve Steam Engine Built by York Manufacturing Co.

The lay shaft is placed in line with the exhaust valves, the bonnets of the exhaust-valve gear being provided with bearings to support the shaft. The exhaust valves are operated by cams acting on anti-friction rollers, effecting a rapid opening and closing. The cams are clamped on the shaft and can be shifted into any position to give the desired release and compression.

The arrangement of lay shaft simplifies greatly the exhaust-valve gear, as eccentrics, straps, rods and levers are done away with.

The steam valves, as shown in Fig. 4, are operated by means of oscillating levers provided with rollers and curved cam pieces attached to the valve spindles, insuring, even at the smallest cut-offs, ample and quick valve openings as well as noiseless operation.

The oscillating levers for both valves are mounted on a single shaft which receives its motion from an eccentric rod and eccentric mounted on the lay shaft. It is noteworthy that this arrangement of the valve gear necessitates the use of but

a single eccentric instead of the four eccentrics usually provided in the standard type of poppet valve engines.

The valves are placed in a horizontal position, well supported by long spindles and guides. The pressure on the valve guide, neglecting spindle guide, amounts to about ½ lb. per square inch. The spindles are lubricated by means of forced lubrication, which passes the oil along the valve spindle through spiral grooves, on to the guide and then into the steam space, thus obtaining a triple effect besides preventing

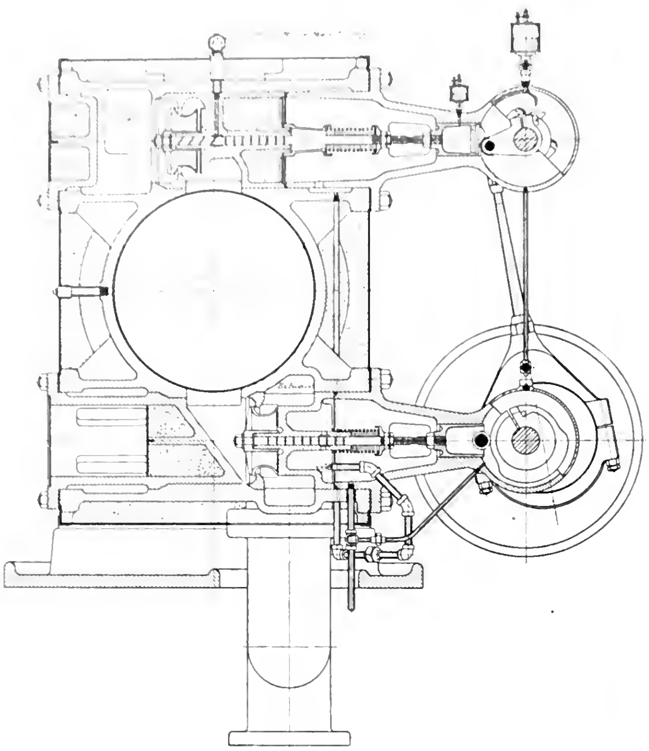

FIG. 4 STEAM VALVES AND VALVE MECHANISM

an escape of steam. The valve spindles are carefully ground into long bushings and provided with labyrinth packings consisting of small circular grooves.

The effective lubrication and the ample support of the valve spindles prevent any bending stresses and preclude the possibility of wear. The horizontal position of the valves and seats is of distinct advantage, as the accumulation of sediment and burnt oil is impossible, the seats being properly cleaned during every steam-admission period.

Of particular interest is the design of the valve cages, which contain not only the valve seats and spindle guides but also the complete structure of the ports. This is a distinct improvement over the usual rib design with its large clearance surface and volume and its unequal expansion. This cage design insures a perfect casting, with a reduction in clearance space not obtained in any other design.

The whole valve assembly is easily accessible by simply removing the back covers without interfering with the valve gear.

The valve-gear parts work in a removable cover, preventing the ingress of dirt, and operate in an oil bath through which the oil may be circulated continuously and used over and over again. Absence of wear and reliability of operation of the valve gear are insured by this arrangement, which is shown in Fig. 5.

A very important part of an engine is the cylinder, and a careful and correct design will prevent great trouble. Early designs, even as late as fifteen years ago, had cylinders in which steam and exhaust chests and cross-overs were cast integral with the cylinder, resulting in a very rigid construction which was not adaptable to high temperatures. As pressures and temperatures continuously increased, it became necessary to separate the two cylinder ends and connect them by means of flexible manifolds. This arrangement allowed a freer and better expansion of the cylinder.

However, it was found advisable also to remove the steam and exhaust chests from that part of the cylinder which was swept by the piston, as under working conditions at high temperatures these stays and ribs caused the cylinder to warp.

In order to meet these conditions, the so-called three-piece cylinder, wherein the valves are placed in a cylinder head and the cylinder proper becomes a barrel with two flanges, came into favor. This design is excellent, mechanically and economically, because it is not subjected to any undue stresses even under high temperatures and pressures, and the steam ports become straight and short, offering small resistance to the steam flow.

However, the cylinder heads constitute difficult, complicated and expensive castings; the erection is awkward and the piston is not very accessible, as steam and exhaust connections have to be broken and valve gears disconnected before the heavy cylinder head can be moved back, usually on slides provided on the extended bedplate.

The author has adapted a one-piece cylinder which it is believed possesses most of the advantages and none of the disadvantages of the three-piece cylinder.

The author's governor arrangement, mounted on a side shaft, is shown in Figs. 5 and 6, for return-flow and uniflow

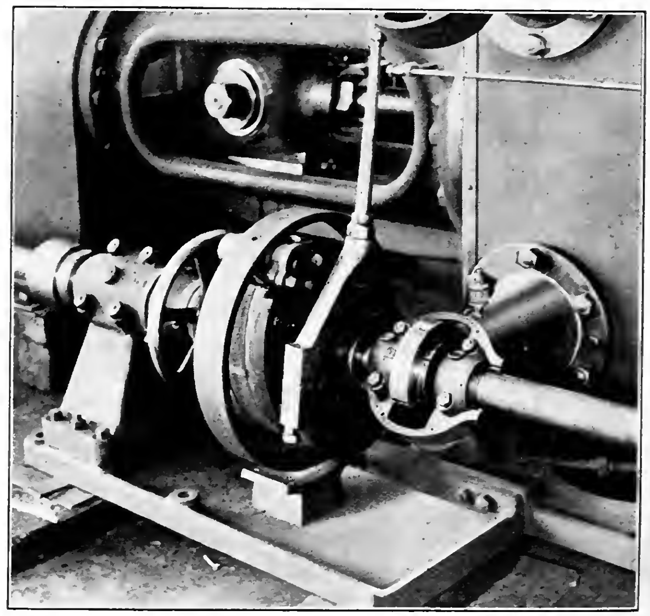

FIG. 5 VALVE GEAR, GOVERNOR AND HAND SPEED ADJUSTMENT

engines respectively. A hand speed adjustment is provided, by means of which it is possible to change the speed while the engine is in operation.

The arrangement of the uniflow engines is generally the same as that of the return-flow engines. The steam valves are operated and regulated in a similar manner as described in previous paragraphs.

A central exhaust port controlled by the piston is provided for the escape of the steam. As this port is of unusually large size—about three times as large as the valves and ports provided in return-flow engines—the release and exhaust of steam takes place very rapidly, and the pressure maintained within the cylinder will be as low as that in the exhaust pipe or condenser. This is a strong point in favor of uniflow engines, as high vacua can be utilized to fullest advantage.

As in the standard type of uniflow engine compression takes place during approximately 90 per cent of the stroke, provision has to be made to overcome excessive compression in case the engine is operated at such back pressures as to cause the final compression pressure to exceed the steam pressure.

The simplest method of decreasing the compression pressure, as used by most designers, is to increase the clearance volume.

After the main exhaust port is closed by the piston, steam is allowed to pass through the auxiliary exhaust valves into the exhaust pipe. The steam travels at a low velocity and is free of moisture, being relieved of pressure and water when the main exhaust port opens, and hence will have practically no cooling effect on the cylinder cover and walls.

The engine built by the Skinner Engine Co., of Erie, Pa., uses auxiliary exhaust valves, placed about 30 per cent of the stroke from the cylinder head, compression commencing as the piston covers up the auxiliary ports.

Several designs of a semi-uniflow type, one of them patented by the author, place the main exhaust valve in the center of the engine. An advantage of this type is that compression is reduced to about 50 per cent, while the clearance of the exhaust valve comes only into action when the steam pressure

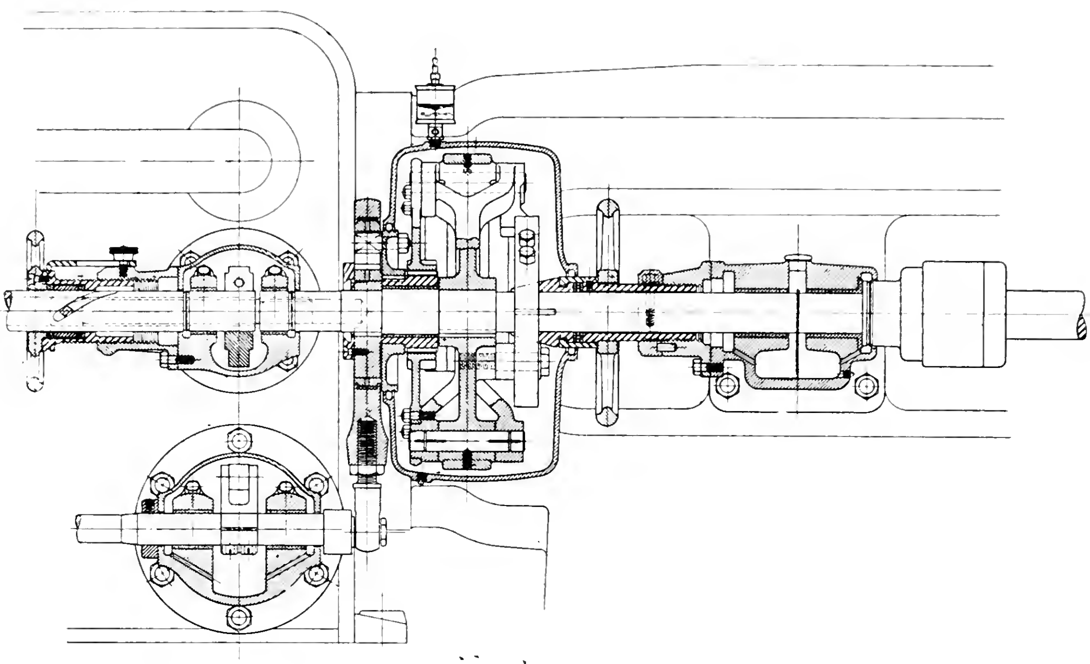

Fig. 6 Section of Valve Cams, Governor and Hand Speed Adjustment

An additional clearance chamber is provided, separated from the cylinder usually by means of a single-seated valve. This valve is operated either by hand or automatically, and the additional clearance chamber connected with the cylinder whenever required by the operating conditions. Such designs have been adopted by the Ames Iron Works, Oswego, N. Y., the Mesta Machine Co., Pittsburgh, Pa., and by most other builders of uniflow engines, being the simplest and easiest way of overcoming the excessive compression.

From an economical point of view, however, this added large clearance surface in particular is very detrimental, and such an arrangement is only permissible when in use temporarily. In case the engine has to operate continuously non-condensing, as, for instance, a locomotive, a concave piston is used which provides the necessary clearance volume, about 16 to 20 per cent of the cylinder volume, with only a slight increase in clearance surface. The added volume is wasteful, and especially so as the cut-offs increase.

In order to reduce the duration of compression, the original builder of uniflow engines, the Englishman Todd, conceived the idea as far back as the eighties of the last century to provide mechanically operated auxiliary exhaust valves, held open during a fixed period.

is low, and hence its detrimental effect is considerably reduced.

While a high compression is advisable and economical in uniflow engines, as amply demonstrated in many tests, it has also been shown that for practically all working conditions 90 per cent compression is excessive.

Stumpf, in his book entitled The Una-flow Steam Engine, says: "The constant compression, always held to be a desideratum in large engines, is fundamentally false. It further follows that the distribution obtained by link motion and shifting eccentric gear is fundamentally correct, as it gives large compressions with early cut-offs and small compressions with late cut-offs."

To what extent the 90 per cent compression in uniflow engines exceeds the most economical compression can be seen from diagrams replotted from the aforesaid book of Professor Stumpf. For example, for an engine working with 170 lb. gage pressure, 197 deg. superheat, 27 in. vacuum, and a cylinder clearance of 2 per cent, the most favorable compressions for different cut-offs as taken from such a diagram, adiabatic compression being assumed, are as follows:

Cut-off, per cent	10	15	20	25
Compression, per cent	70	58	50	45

For poorer conditions of exhaust, i.e., less than 27 in. vacuum, a compression of still shorter duration should be maintained for [illegible].

With these points in view, the author designed a uniflow engine and provided it with auxiliary exhaust valves and gear

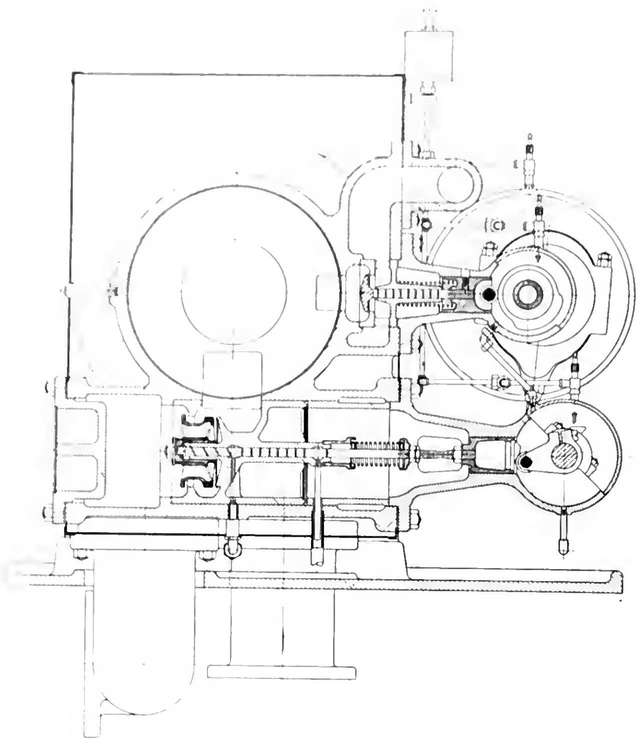

Fig. 7 Exhaust Valve, Auxiliary Exhaust Valve, and Valve Gear

controlling compression for any and all operating conditions.

The auxiliary exhaust valves are of small diameter, single-seated yet balanced, as they open under no difference in pressure on either side of the valve. The added clearance space due to these valves is negligible.

These auxiliary valves are operated by a continuously rotating camshaft (Fig. 7), an arrangement which has been adopted by the York Mfg. Co. The cams can be shifted on the shaft while the engine is in operation. A suitable disposition for exhaust port is still open) and closes about 15 per cent before the other dead center is reached. A compression ranging between 70 per cent and 15 per cent of the stroke is suitable for practically any working condition.

The camshaft is rotatably shifted by means of a handwheel, pin and spiral groove (Figs. 8 and 9), and clamped in the desired position. A dial indicates to the engineer for what degree of compression the cams are set. It is obvious that this device may be operated automatically by using instead of the handwheel a piston subjected to the difference of exhaust and atmospheric pressure.

On engines operating continuously condensing the auxiliary exhaust valves may be dispensed with and be replaced by valves which connect with the additional clearance space in case the vacuum fails, an arrangement adapted for the standard uniflow engine.

A uniflow engine without auxiliary exhaust valves and without side shaft has been developed by the author for driving the small high-speed ammonia compressors built by the York Mfg. Co., Fig. 10. Identically the same cylinder design is used as for the larger-size machines, but governor and eccentric are placed on the main shaft and the valves operated by means of a reciprocating camshaft.

One of the difficulties in poppet-valve engine construction is to design and manufacture the valve and seat in such a way that they expand equally and maintain steam-tightness under any other temperature than that at which they were ground together.

Good results have been obtained by making valve seats and valve proper of similar shape, likeness and material. However, such an arrangement is not always possible, and valves adjusting themselves to any expansion of the seats are often preferable.

In the design of the Ames Iron Works the upper seat is of thin, flexible steel, and by making the valve somewhat unbalanced this seat is pressed down by the steam pressure until the metallic surfaces meet. The original Stumpf design uses a valve made entirely of steel.

The author's design of a self-adjustable valve is shown in Fig. 11. Due to the peculiar construction of this valve, which is balanced to the same degree as any other standard poppet valve, the upper half will lift under an excess of pressure within the cylinder or in case of a slug of water, and thus constitutes a relief valve of extraordinary large area. As this

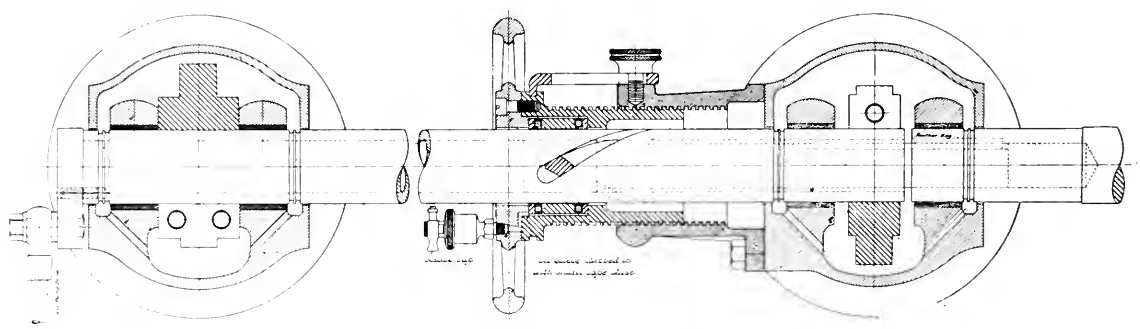

Fig. 8 Valve Gear for Auxiliary Exhaust Valves

release and compression can be obtained, for instance, by opening the auxiliary valves, say 7 per cent before dead center, closing them 30 per cent after dead center—equal to 70 per cent compression and recommendable for condensing work; while for non-condensing operation the cams can be shifted into the other extreme position, when the auxiliary valve opens about 7 per cent after dead center (the main

feature is combined with the admission valve, its safe operation as a relief valve is absolutely insured and the difficulties usually encountered with relief valves avoided. The part of the valve effecting relief lifts only against steam pressure and a spring of light tension and is in no way affected by the tension of the main spring.

Another feature of this valve lies in the fact that it lifts

practically against no steam pressure, as pressures are equalized above and below the seats as soon as the lower valve part is lifted.

As this valve will adjust itself to any expansion of the valve seats, it can be ground in when the cylinder is cold and remains steam-tight under any temperature.

Fig. 12 shows cards taken from a uniflow engine with variable compression as made by the York Mfg. Co.

THE LOCOMOBILE

Considerable favor has been given in the last few years to a very unique and compact power-plant arrangement—the so-called "locomobile," which is a combination of an engine placed on top of a boiler with a superheater, condenser, air pump, feedwater heater and feed pump. In other words, a compact, high-class and self-contained power plant which is extensively used in isolated plants and for farm purposes in Europe and South America.

The success of the locomobile is primarily due to the close combination of boiler and engine whereby heat is transformed into power on the shortest path possible. Designers of plants for stationary engines have nearly always sacrificed these thermal advantages to arrangements which were dictated by an exaggerated sense of safety and conservatism. The success of the locomobile fully demonstrates that a much closer arrangement of boilers and engines has become an economic necessity.

Remarkable economies have been obtained with these engines. Steam consumptions of 8 lb. and coal consumptions of 1 lb. per i.hp. per hour, in units of 100 to 200 hp., are nothing unusual in compound engines, and that with working conditions not exceeding 200 lb. pressure and 300 deg. fahr. superheat. Though these engines are particularly attractive in the smaller sizes, say, up to 300 hp., considerably larger units have been built by several German concerns. A Lentz locomobile of 1000 hp., built by Heinrich Lanz., of Mannheim, Germany, was exhibited at the World's Fair in Brussels in 1910.

In cross-compound engines of this type the two high-pressure admission valves are operated by one cam and one eccentric, the travel of which is regulated by the governor; while the two high-pressure exhaust and four low-pressure valves are operated by a single camshaft on which the three cams are mounted.

A somewhat simplified arrangement is obtainable by using the high-pressure exhaust valves also as admission valves to the low-pressure cylinder.

The cranks are set on 180 deg. and the indicator cards are typical of an engine without a receiver, a so-called "Woolf" engine.

Two very interesting tests carried out on such a type of engine are given herewith. They are noteworthy on account of the steam pressure and superheat carried and on account of the remarkable economies obtained.

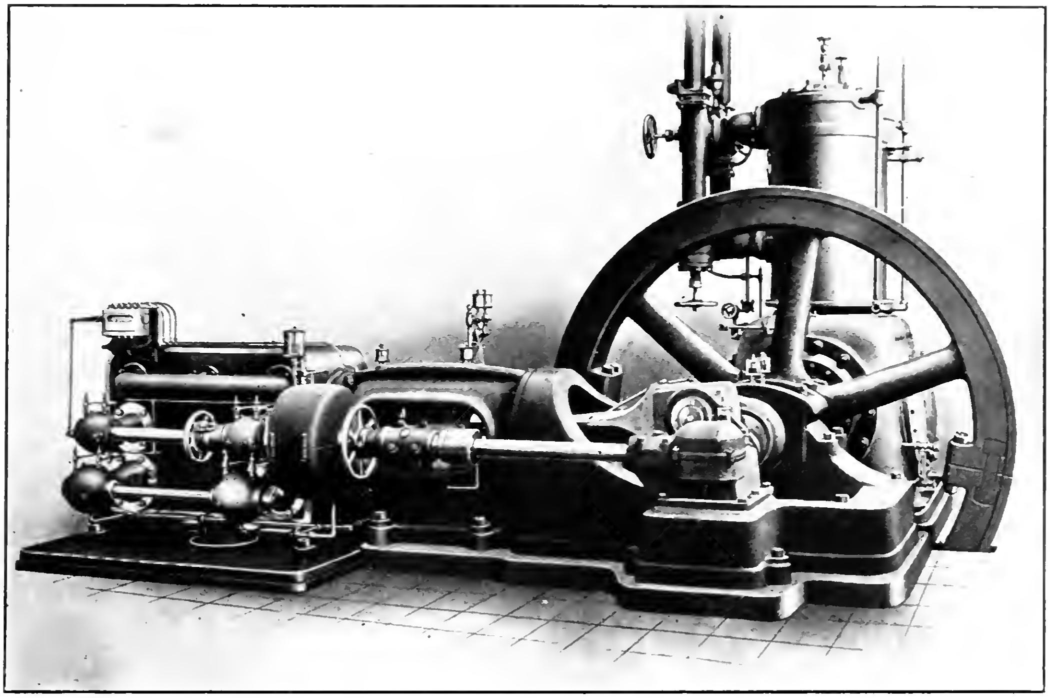

Fig. 9 Poppet-Valve Semi-Uniflow Steam Engine

Steam pressure, lb. per sq. in., gage	213	432
Temp. of high pressure steam, deg. fahr	923	1018
Indicated horsepower	112	99
Revolutions per minute	150	158
Vacuum, inches of mercury	27.7	26.7
Steam consumption per i.hp-hr. lb	6.53	5.68
Heat consumption per i.hp-hr., B.t.u	9720	8640

It is interesting to compare these results with those obtained from a poppet-valve engine of the steam car of the White Motor Co., Cleveland, O., which was so successful before the modern development of the gasoline car set in.

Professor Carpenter, of Cornell, tested one of these engines and obtained with a steam pressure of 427 lb. and a steam temperature of 767 deg. fahr., operating non-condensing, an economy of 12.29 lb. per b.hp. per hr. These results can also be considered quite remarkable, especially in view of the fact that the bores of the high- and low-pressure cylinders were only 3 in. and 6 in., respectively, the stroke $4\frac{1}{2}$ in., and the speed 850 r.p.m.

The uniflow cylinders have also been used considerably in connection with locomobiles. Economically, however, the locomobile has shown no marked superiority over the return-flow

poppet-valve engine, as the heat losses peculiar to stationary engines are considerably reduced on account of the arrangement of the locomobile.

Simplicity of cylinder and valve-gear design, on the other hand, makes the uniflow locomobile a very attractive unit. Usually platforms and stairs are provided to give access to all parts. In some plants, especially where several units are installed, a floor is laid above the boilers, and in this way the boiler and engine rooms are separated.

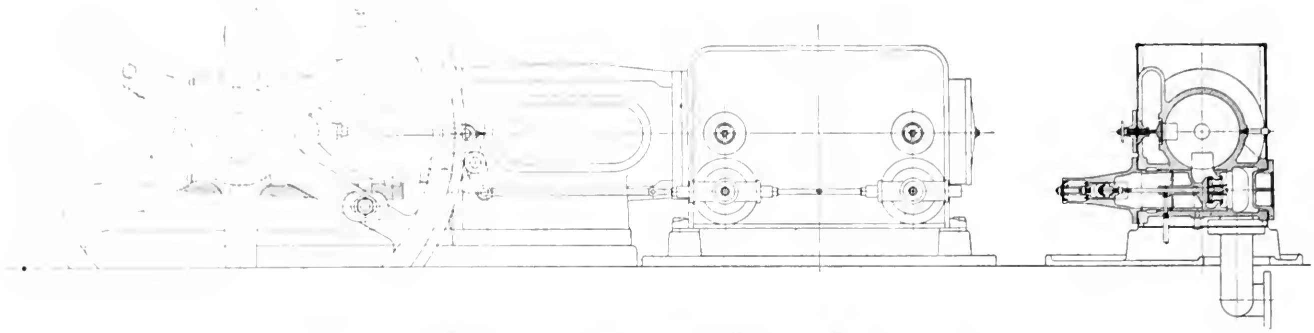

Fig. 10 Poppet-Valve Uniflow Steam Engine Without Auxiliary Exhaust Valves

THE MARINE ENGINE

In order to ascertain the applicability of superheated steam and poppet-valve engines to steamships, the Compagnie Générale Transatlantique, of France, ordered in 1905 from the navy yard of St. Nazaire, two cargo boats, the *Rance*, the two boilers of which were fitted with superheaters and the engines with poppet valves, and the *Garonne*, fitted with the ordinary type of marine engine without superheater.

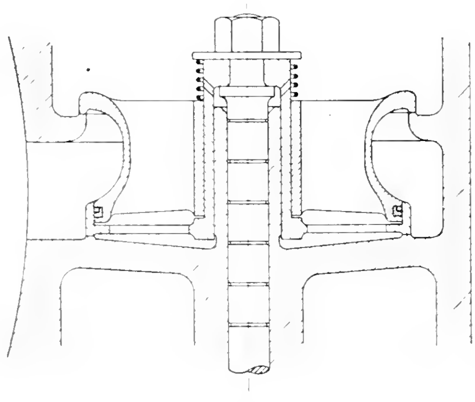

Fig. 11 Self-Adjustable Poppet Valve

Tests made under identical conditions showed that, due to the superheater and poppet-valve engines, an increase of power of 18.1 per cent and a decrease in coal consumption of 20.1 per cent were obtained.

A great simplicity of valve-gear arrangement is possible with these poppet-valve engines, as is apparent from a study of the cross-sections of some typical triple-expansion engines. These show not only a grand housecleaning of moving parts, but also very ingenious arrangements for the disposition of the valve-gear parts.

As a rule, separate steam engines are provided for reversing marine engines, but in this case the usual reversing engine is dispensed with and replaced by a hand-operated reversing gear, very little power being required.

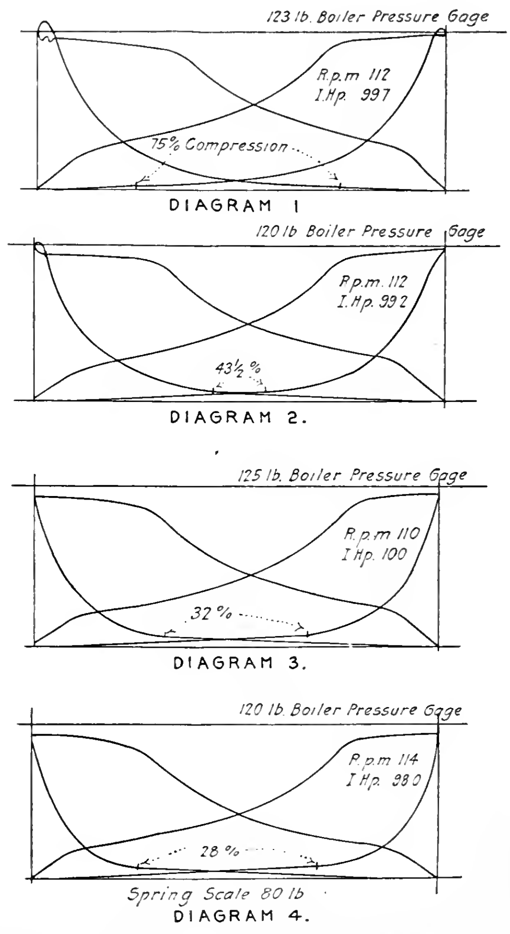

Fig. 12 Cards Taken from Uniflow Engine with Variable Compression

A torpedo-boat engine of striking construction of 6000 hp. was exhibited in Brussels in 1910. This engine is rather unique in its arrangement, being a compound engine having

three low-pressure and one high-pressure cylinders. All four cylinders and sixteen valves are of the same diameters, respectively. The corresponding valve-gear parts are alike for the different cylinders and for that reason are all interchangeable.

Uniflow cylinders have also been applied to marine engineering with considerable success in the last few years, on account of the simplicity of cylinder and valve-gear arrangement, enhanced by the fact that all cylinders belonging to one engine are exact duplicates.

The valves are mostly arranged in a horizontal position and operated by a valve gear of similar design to that used for stationary engines of the uniflow type.

THE LOCOMOTIVE

The first concern to equip locomotives with poppet valves was the Hannoversche Maschinenbau A. G., of Hannover, Germany. Preliminary tests were made in 1905 on an old tank locomotive which happened to be at the shops of this concern undergoing repairs. These tests were made after the old slide-valve cylinders were replaced by cylinders fitted with poppet-valves and Lentz gear.

The results were highly satisfactory to the advocates of poppet valves and superheat on locomotives, as with a steam temperature of 520 to 540 deg. fahr. the poppet-valve locomotive showed a saving in water to the extent of 30.6 per cent and a saving in coal of 19.5 per cent as compared with the slide-valve locomotive working with saturated steam.

On the small pilot locomotives and on the newest express locomotives the poppet valves are arranged horizontally and worked by cams mounted on a horizontal shaft which is oscillated from the eccentric rod by means of a small crank arm.

On the older express locomotives the four valves were placed in a vertical position above the cylinder, in a row one behind the other, the two admission valves toward the middle and the two exhaust valves toward the ends of the cylinder. The cam rod has four symmetrically arranged lifting curves which engage when in contact with the rollers on the valve spindles. The camshaft receives a reciprocating motion from the link gear and raises the valves alternately. The whole valve-gear box is removable from the cylinder, making inspection and replacing of parts a very simple matter.

Uniflow engines on locomotives have shown good results and seem to give better results than the return-flow poppet-valve engines at light and medium loads, while the superiority seems to rest with the latter type at the heavy loads.

It is difficult to say how many poppet-valve locomotives are in service now, but according to the author's information there were several hundred in operation in Germany before the war broke out, and a large number in England, France, Belgium, Austria, Switzerland, Russia, and also in the Scandinavian countries.

It is apparent from what has been said and shown in the foregoing pages that the modern development of the poppet-valve engine has revolutionized steam engineering and has made possible arrangements and working conditions and produced results which were, until recently, considered beyond reach.

Designers and manufacturers would do well to consider the importance and recognize the truth of the principles presented, as the conservation of our natural resources—which have been wasted to a lamentable extent for many years past—has become a matter of great cultural and economic importance.

CORRESPONDENCE

Contributions to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Mobile Armament for Defense

To the Editor:

In Mr. Coyle's paper on Mobile Armament for Defense, the importance of having some standards for calibers of guns was not mentioned. This feature is, of course, well understood by military men and provision is made for this to a certain extent, but not enough stress is laid on the matter.

The calibers, bores, breech mechanisms and firing devices for different types of guns should be so standardized that ammunition could be used by either the army or navy and, if possible, by the allies. That is to say, all revolvers and pistols are to have the same caliber and the same cartridges and all rifles are to use the same cartridges. All 1-lb., 3-in., 12-in., etc., projectiles are to be of the same outside dimensions to fit the corresponding-sized gun. This would simplify the problem of munition manufacture and be of vital importance in many cases where shortage of ammunition of a certain size might occur in action.

I have doubt about the practicability of the gun mentioned which has the breech plug sliding against a hardened curved surface. I think that in firing the gun the pressure or blow which would be caused by the discharge would roughen or dent the curved surface so much that the friction would give trouble in elevating and depressing the piece. With reference to the supports on arms shown in the diagrams, with the jackscrews at the ends, I think something on the lines of a tripod, well braced at the sides, designed on the trails for long-recoil field guns and siege howitzers, would give better satisfaction. This would take care of the horizontal fire; the high-angle fire could be taken care of by some substantial supports nearly under the trunnions of the gun.

The question of independent drive for armored trucks and cars of this kind is a very important matter and I am anxious to see something developed and put into commercial use along the line of explosive engines using alcohol instead of gasoline, as it will have to come to this sooner or later.

Arthur F. Cary.

Watertown, Mass.

Problems in Waste Disposal

To the Editor:

The writer considers that a wise choice was made when the reduction process was decided upon for the city of Chicago for the disposal of garbage, although there might be much

room for argument over the use of the drying (Mertz and Simonin) method of reduction. For cities of large and moderate size any one of the three principal reduction methods mentioned may now be used to dispose of garbage in a sanitary manner and with freedom from nuisance. In general, reduction will be found to be much more economical and will show a decidedly higher percentage of successful installations in this country than will incineration. Incineration is the general method employed in Europe, but it has not attained success here because of different conditions encountered.

If service, cost and sanitary results were on a par between reduction and incineration for a given city, I should favor reduction because the question of conservation of our resources is involved. Reduction saves for us valuable products, returning fats and oils to the industries and plant food in the form of tankage to help enrich our soils, whereas incineration destroys and wastes them.

Concerning the author's statement that tankage and grease produced by the drying process are of better quality than by the cooking process as used at Cleveland, Columbus and elsewhere, it is interesting to compare prices received in 1917 for these products as follows:

	Drying Process	Cooking Process	
	Chicago.	Cleveland.	Columbus.
Grease, per cwt........	$7.29	$8.01	$7.52
Tankage, per ton.......	7.00	10.00	11.00

The grease contracts of Chicago and Cleveland were made at about the same period, while the Columbus contract was made when the market was considerably weaker. In the case of tankage the Chicago price is the market price quoted by the author for Chicago and not the actual contract price. For Cleveland and Columbus the prices of tankage fluctuate slightly, being dependent on the analysis of the product, but will average about as given.

The author refers to Dr. Morgan's claim to a process for the production of alcohol from garbage. This process is particularly applicable as an addition to the cooking process of reduction and it has been the writer's privilege to have recently conducted practical tests on the process, during which tests a large amount of the technic of the process was developed. It may be said that the process is entirely practical but that its success financially at its present status is dependent upon market prices of alcohol and certain chemicals and upon the quality of the garbage treated.

Although different ideas may prevail concerning the methods and equipment used in the Chicago plant, much originality in arrangement and selection of apparatus has been shown, which should be beneficial to the industry. The plant should make an excellent record now, due to the fact that high prices for products prevail, and due also to the equipment being new and repairs and maintenance being at a minimum.

T. D. Banks.

Columbus, Ohio.

WORK OF THE BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

Below are given the interpretations of the Committee as approved by the Council on July 15, 1917, in Cases Nos. 162-166 inclusive. In this report, as previously, the names of inquirers have been omitted.

Case No. 162

Inquiry: Is it permissible under the A. S. M. E. Boiler Code, that safety valves bearing all the markings called for by the Code, may be sold as conforming to Code requirements, when their lifting devices fail to raise the valves from their seats as required by Par. 282?

Reply: The Boiler Code requires that a safety valve be provided with a substantial lifting device and shall have the spindle so attached that the valve disc can be lifted from its seat not less than one-tenth of the nominal diameter of the valve when there is no pressure on the boiler. The Code does not specify the character of the lifting device.

Case No. 163

Inquiry: Does Par. 317 of the A. S. M. E. Boiler Code and the interpretation in Case No. 110 apply in the case of a boiler plant where duplicate feed lines are used, one of which conforms strictly with Par. 317, while in the other there are no stop valves between the check valves and the boilers?

Reply: It is the opinion of the Boiler Code Committee that Par. 317 of the Code is intended to mean that a valve shall be placed between the boiler and a feed check wherever a feed line is used.

Case No. 164

Inquiry: What is meant by the latter portion of Par. 207 of the Boiler Code which provides for greater spacing between rows of staybolts than indicated in Table 3? Is there not an inconsistency in the language that should be cleared up?

Reply: Par. 207 is designed to cover constructions in water-leg boilers where the portion of the sheet which comes between rows of staybolts is reinforced through the flanging-over of the edge of the handhole openings. It is evident that where the handhole openings are flanged to a depth of, say, twice the depth of the plate, that the transverse strength is increased over what it would be should there be no such flanging. In cases of this sort, the construction may be considered a beam fixed at each end, the beam to have a factor of safety of at least five.

Case No. 165

Inquiry: In view of Par. 274 of the Boiler Code, which states that only water heating surface, and not superheating surface, is to be considered in determining the minimum sizes of safety valves, an opinion is requested as to what portion of the tube surface of vertical tubular boilers shall be considered superheating surface.

Reply: It is the opinion of the Committee that for the purpose of determining the minimum sizes of safety valves to be used in vertical fire tube boilers, the tube surface above the center line of the upper gage cock should be considered as superheating surface. See Par. 274 of the Code.

Case No. 166

Inquiry: Is the maximum allowable working pressure of a locomotive boiler limited by Par. 194 of the Boiler Code, where a special flanged ring construction is used at the base of the dome instead of flanged dome sheet construction?

Reply: It is the opinion of the Boiler Code Committee that the construction referred to, involving special flanged ring construction independent of the dome sheet at the base of the dome, comes under Par. 261 of the Code and must conform thereto.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

WORK at headquarters has been as active during the hot weather and the so-called vacation period as at any time in the Society's history. Visitors from Russia, Australia, South Africa, South America and Japan have been received and special attention given them, as is the Secretary's custom.

We have for quite some time been trying to make the Society a medium for the interchange of technical knowledge and the development of cultural relations with other countries, and it is gratifying to see the extent to which the Society has succeeded.

Also, a large number of members have called. Several of the committees have been meeting regularly, notably the Committee on Engineering Resources, which, through the classification of the members, is furnishing all departments of the Government and the industries generally with names of specialists for any emergency. We have studied the classification systems of the Government, the insurance companies and the universities, and we think we have the most comprehensive of any. This service is free, and is the Society's contribution to the efficiency of the nation.

The progress on the alterations and enlargement of the Engineering Societies Building is satisfactory, and by the middle of October, if not sooner, quarters will be ready for the American Society of Civil Engineers.

Taking advantage of the construction period, this Society is having some much-needed improvements made in its quarters. All of the editorial and clerical rooms are being thrown into two large rooms and sound-deadening ceilings installed similar to those in the new portions of the building now under construction, and in modern offices generally.

The members on the Pacific Coast are looking forward to the visit of President and Mrs. Hollis in October. Another feature will be a Council meeting in November in Chicago, thus developing the contact between the representatives of the Society and the members.

CALVIN W. RICE,
Secretary.

WHAT THE SECTIONS HAVE DONE THIS YEAR

THE first of the Sections yearly reports were published in the August issue of THE JOURNAL, together with an account in general of the Sections activities throughout the past year. The spirit of coöperation developing among the Sections and the local branches of the other engineering societies was commented on at length as a sign favorable both to the Sections themselves and the Society nationally.

The reports published last month included those from Baltimore, Buffalo and New York. Similar reports have since come to hand from other Sections and are published below.

Next month the Committee on Sections will outline the proposed activities of the Sections for the coming season, and the month following the programs of coming Sections meetings will be announced.

ATLANTA

The meetings of the Section have been irregular, but approximately monthly, and a number have been held with the Affiliated Technical Societies of the City of Atlanta. The average attendance at these meetings is 30 per cent, but on special occasions as many as 75 per cent of the members are present.

Among the most important meetings held should be mentioned the following: On January 16 Ira N. Hollis, Pres.Am.Soc.M.E., addressed the Affiliated Technical Societies of Atlanta on the subject of the part being pl yed by the Engineer and the Engineering Societies in Modern Life, appealing to them for concentration of efforts in the war against nature in the preparedness, conservation and promulgation of the country's welfare. Dr. Hollis laid great stress upon the efficient application of power, force and resources, showing very clearly to his audience the real value of the engineering societies and the results of their combined action, and the necessity of concerted action to obtain the highest efficiency in the general results of time, by the war against nature, so necessary to place the country in a state of preparedness which would enable us to use in the most efficient manner the natural, artificial and resourceful products of the country.

In March Lieut.-Col. Lytle Brown, Engr. Corps, U.S.A., gave a very interesting and instructive address on The Engineer in Modern War.

The membership also visited the works of the Atlantic Steel Co., on the invitation of the secretary and treasurer, who is a member of the Society.

OSCAR ELSAS,
Section Chairman.

BIRMINGHAM

Birmingham has had many meetings during the past year, which proved of much interest and help to those present.

The first took the form of an excursion to the Avondale Works of the Continental Gin Company and the plant of the Coyne and Joubert Foundry Company. Among the subjects of special interest at later meetings were The Use of By-Product Coke-Oven Gas as a Fuel and some of the Problems Presented in Its Use at the Ensley Steel Works, by W. P. Caine; The Manufacture of Cast-Iron Water Pipes, by Paul Wright; The Place of the Engineer and the Engineering Societies in Modern Life, by Dr. Ira N. Hollis; The Locomotive Firebox and Combustion Chamber, by J. J. Anthony; Illumination, by Prof. A. A. Wittig; Technical Writing, by Prof. M. Thomas Fullan.

During the year the hearty coöperation and support of the two state universities has been enlisted and two representatives from each have addressed the Section. The Section has also been influential in the organization of the Alabama Technical Association, which includes all the members of the national engineering societies residing in the state of Alabama, of whom there are over two hundred.

PAUL WRIGHT,
Section Chairman.

BOSTON

The season opened with a combination trip to New London for the inspection of submarine design, construction and operation, which was greatly enjoyed by some four hundred members and

[illegible] from Boston, Worcester and Providence. The day included luncheon at the hotels, a trip down the bay on Government steamers, where surface and submerging practice was carefully watched, followed by a return to the works of the Electric Boat Company at Groton.

The next meeting consisted of a trip to the General Electric Works at Lynn, and a further inspection of the United Shoe Machinery Shops at Beverly, followed by a dinner at the clubhouse, with an illustrated lecture on the Turbo Drive for Ships, by W. L. R. Emmett, Mem.Am.Soc.M.E.

On February 7 the meeting consisted of the annual combined banquet, at which very interesting talks were given by Dr. Richard Cabot, who was preparing another hospital unit for France, and by E. W. Ewartz, who delivered an illustrated lecture on submarines. At this meeting a resolution was adopted and forwarded to the President of the United States endorsing his stand and offering the services of this Section. This was probably the most successful dinner ever held in the Boston Section and was attended by about five hundred members and guests.

The meeting held on March 8, under the A.I.E.E., covering electric transmission for vehicles both for the railroad and ordinary road work, was attended by our membership.

The Power Plant Meeting was held April 4 and 5 at the Engineers' Club and the Wentworth Institute, the meetings being held under the direction of Professors Hutton and Williston. Papers were read by several exponents of municipal and independent plants and descriptions given of some modern plant apparatus.

The spring meeting was held at Marblehead, April 17, where the hydroplane plant of the Burgess Company was inspected. In the evening, at Wentworth Institute, the Section was addressed by several engineers connected with this industry.

The season has been exceptionally interesting, not only on account of the increasing influence of engineering work in modern civilization, but also because of the enormous expansion of all the industries connected with the war.

A. L. Williston,
Section Chairman.

CHICAGO

The meetings during the past year have been well attended and a lively interest taken in the various subjects presented.

Four meetings were held during the season, the first and last being devoted to military subjects and the intervening gatherings to semi-technical topics such as oxy-acetylene welding and problems in waste disposal.

The dinner plan of meeting was continued, and for the first time the Section had a "ladies' night." This latter feature was a great success from a social point of view, and it is planned to continue it next year and also introduce innovations tending to enlarge acquaintances and bring the members closer together.

Joseph Harrington,
Section Chairman.

CINCINNATI

The Cincinnati Section is affiliated with the Engineers' Club of Cincinnati, an organization about 30 years' old. At three or four meetings a year the program of the Engineers' Club is carried out by the Cincinnati Section of the A.S.M.E. The chairman of the Section presides, the paper and its discussion being arranged by the officers of the Section. This provides an audience larger than the club could provide of itself.

At the present time the number of local members credited to Cincinnati in the 1917 year book is 94. There are, however, a number of members in St. Bernard, Norwood, Ivorydale, Ohio and Newport, Kentucky, who meet with the local members. In addition to these there have been quite a number of recent applications, which brings the total number of members in the Section to 135.

This Section has been fortunate in having speakers of prominence address the various meetings during the year, on subjects of much interest.

Among these was one on Some Present and Future Carburetion Problems, by C. F. Kettering, Mem.Am.Soc.M.E., and vice-president of the Dayton Engineering Laboratories Company. Mr. Kettering is largely responsible for the Delco lighting systems for motor cars and for the Delco-Light for small isolated electric lighting plants, and handled his subject in such an extremely interesting manner that he succeeded in holding his audience fascinated for two hours. Abner Doble, inventor of the Doble steam car, also gave an interesting paper, which has since appeared in The Journal, entitled The Steam Motor Car.

Much time was spent in making preparations for the Spring Meeting of the Society, one result of which was the Joint Meeting with The National Machine Tool Builders' Association on May 22, at which time papers were read by H. Schneider, Dean of the University of Cincinnati, on The Trend in Engineering Training, and by Dr. Otto P. Geier, on The Human Potential in Industry.

F. A. Geier,
Section Chairman.

DETROIT

A series of meetings of members of the Am.Soc.M.E. residing in Detroit and neighboring Michigan cities, led to the organization in October 1916 of this Section. It is the intention that this Section shall serve a territory around Detroit of approximately ninety miles radius.

It was decided to hold quarterly meetings which will not interfere with the meetings of the local associations. The Section's especial province seems to be to gather together the Society members of the district in order to bring them into contact not only with each other but with the leaders of the national organization; at the same time members of other engineering societies are invited to attend its meetings.

The two meetings held during 1917 were made of a social character. Members and their guests had dinner together before the meetings. Both were held at the Detroit Board of Commerce Building in order that the Section might become better known in the business life of the community. Members had the opportunity of listening to Ira N. Hollis, Pres.Am.Soc.M.E., and John W. Lieb, Mem.Am.Soc.M.E.

M. E. Cooley,
Section Chairman.

ERIE

The Erie Section has recently adopted the rule of holding at least four meetings a year, two to be dinner meetings at which the regular affairs of the Section will be taken up and two meetings will be held in conjunction with the Engineers' Society of Northwestern Pennsylvania, the Section to furnish the speakers.

The Section is one of the newest and regards its first year as one of experience. Adoption of the above program will ensure plenty of work for the coming season.

J. F. Wadsworth,
Section Chairman.

INDIANAPOLIS

The Indianapolis Section was organized in October and the first three meetings were devoted to the completion of this organization.

In February a meeting was held in conjunction with the A.I.E.E., at which Harrington Emerson, Mem.Am.Soc.M.E., spoke on Efficiency and the Engineer.

Several other meetings were planned, but were abandoned in order that the entire energies of the members might be devoted to preparedness work and the formation of a battalion of engineers.

Plans for the fall and winter are now being worked out and it is expected that there will be many discussions of interest.

W. H. Insley,
Section Chairman.

MINNESOTA

The Section has had some very interesting meetings in conjunction with the local branch of the A.I.E.E., and has also been honored with invitations from the Chemical Engineers and the Engineers' Club of Minneapolis. A very cordial feeling exists between the Minnesota Section and the other engineering interests and societies of the State.

This spring it was planned to join with the A.S.C.E. in a trip

to Duluth, Minn., but the war situation postponed the visit of the national society.

Probably the most successful meeting during the year was the Locomotive Session, when there were fifty railroad representatives in attendance and a large number of papers were read.

A banquet was also tendered Ira N. Hollis, Pres., Am.Soc.M.E., which was by far the biggest event of the year, and it may be noted in passing that the Am.Soc.M.E. is the only national society that has thus honored its sections.

The Committee on Sections has been urged to work out a plan whereby the more remote Sections may be able to meet and hear some of our most distinguished engineers.

The Section acts as a "big brother" to the Student Branch at the University of Minnesota and its influence with the students is evidenced by the interest they take in the Society and the possibilities of membership in it. Many of the students enter the Junior grade at the time of their graduation or shortly after.

A very important feature of the Section's activities is the means of bringing the local engineers together on a common basis and fostering by social contact a better understanding among those engaged in different engineering lines which could not well be accomplished in any other way.

The members of the Section were, on July 28, invited by Oliver Crosby, Mem.Am.Soc.M.E., to a picnic at his new home, "Stone-Bridge."

A large number of our members and their wives availed themselves of the opportunity to meet in a social way and all had a most enjoyable time. The fact was impressed upon the minds of those present that the engineers do not get a fair share of enjoyment out of life by a policy of "all work and no play," and it was noted that an affair of this kind offers a splendid opportunity to invite engineering friends, who may become better acquainted with the members, and in this way become interested in joining the Society.

The members are looking forward to the time when all the local engineering interests can be united so as to have a common meeting place and possibly an engineering society building.

J. V. Martenis,
Section Chairman.

MILWAUKEE

We have completed the best year of our existence, our meetings being largely attended. During the early part of the year, before we secured our present permanent quarters at the City Club, we found ourselves slightly handicapped, but are now enjoying an excellent attendance, averaging over 150 members at each meeting.

The first meeting of the year, on September 13, 1916, was held at the plant of the Federal Rubber Company, Cudahy, Wis., under the direction of E. Hutchens, Mem.Am.Soc.M.E., who is supervising engineer of this company. L. J. D. Healey, chief chemist of the company, gave a talk on The Growing and Gathering of Rubber Latex. After the lecture the members were taken on an inspection trip around the plant. The Federal Rubber Company gave the Section a supper and showed moving pictures of the rubber industry. This was considered one of the best meetings we have ever held.

The next meeting held under our auspices was on October 11. Prof. J. G. Callan, of the University of Wisconsin, gave a very interesting talk on Recent Tendencies in Gas-Engine Design, illustrated with pictures of the latest types of automobile, aeroplane and submarine engines.

On January 6, I. N. Hollis, Pres.Am.Soc.M.E., gave a talk on The Place of the Engineer and the Engineering Societies in Modern Life.

William M. White, manager of the hydraulic department of Allis-Chalmers Mfg. Co., gave a talk on April 11 on Modern Hydraulic Turbines. There was a large attendance and Mr. White showed the audience views of the latest types of hydraulic turbines.

We try to arrange to have a supper for the speaker before each meeting, which is generally attended by the board of directors of our affiliated societies, and after the meeting a buffet luncheon is always served. We find that a great many of the members stay after these luncheons, standing about in groups and talking on various subjects, and in this manner become better acquainted than they would in any other way.

Edward Hutchens,
Section Chairman.

NEW HAVEN

While the conditions at New Haven do not offer opportunity for much coöperation, the Section has shown the greatest willingness to take advantage of any chance presenting itself. The meetings of the Section have been of service to the engineers of the whole state of Connecticut, and it is recognized that better results can be obtained through more systematic organization.

A Section for the state has been planned which will provide for the usual fall and spring meetings at New Haven and additional meetings at certain other localities in the state where Branches will be established.

Following the plan of former years, this Section has held two principal meetings. The Mining Department of the Sheffield Scientific School invited the Section to meet in the Hammond Laboratory in November, at which time the equipment of the mining laboratory was explained to those interested and a paper on Applied Metallography, by Prof. C. H. Mathewson, was read.

The evening session was held in the lecture room of the Mason Laboratory with F. B. Gilbreth, Mem.Am.Soc.M.E., and S. J. Berard as speakers.

The recently organized Winchester Engineering Club, composed of over 100 members of the engineering department of the Winchester Arms Company, was invited to join the New Haven Section in its spring meeting on April 19, 1917. This meeting was varied by an excursion to two of the pumping stations of the New Haven Water Company, and was followed by a dinner and social hour and an evening session with two illustrated papers on pumping engines for manufacturing purposes.

Informal local meetings have also been held and it is hoped that the new year will see much added interest.

H. B. Sargent,
Section Chairman.

NEW ORLEANS

The first year's work of the New Orleans Section has been a very successful one.

Due to there being in existence an active local engineering society at the time the Section was formed it was considered best to hold but four meetings of the A.S.M.E. Section. These meetings were in every case held jointly with the local section of the Civil Engineers, and as the meetings were held in the rooms of the Louisiana Engineering Society and the members of that society were invited to attend, the meetings were in fact practically extra meetings of the latter society.

The tentative plan for next year is to have the Louisiana Engineering Society assign each of the local sections of the national societies a meeting at which some member of the section in charge will read a paper of special technical interest to the members of that society. The business meetings of the local sections will be held after the general meeting has adjourned. This plan has yet to be submitted to the societies interested, and approved.

The executive committee for next year will be: Chairman, R. L. Radcliffe; secretary, E. H. Tenney; E. Flad, W. A. Hoffman and H. R. Setz.

W. B. Gregory,
Section Chairman.

ONTARIO

As this Section is so new, having been established in May of this year, there is little to report in the way of sectional work. It might be mentioned that the mechanical engineers, through the local section, obtained representation on the Joint Committee of Technical Organizations.

Plans are being made for the coming year which we trust will prove of interest and value to all the members.

G. V. Ahara,
Section Chairman.

PHILADELPHIA

The activities of the Philadelphia Section during the past year have been marked by the coöperation which it has had with the other engineering societies of that city. In the first place the plan of affiliation of the Section with the Engineers' Club has

with [illegible] very successfully and has many advantages to commend it. The Engineers' Club has become the headquarters for Section [illegible] the dining room of the Club is available for Section members, and when desired special dinners can be held there.

Besides the A.S.M.E. Section the local branches of the following organizations are affiliated with the Club: American Society of Civil Engineers, American Institute of Electrical Engineers, American Society of Heating and Ventilating Engineers, Illuminating Engineering Society, Society of Automobile Engineers, Massachusetts Institute of Technology and the Worcester Technology Club.

An advantage of the affiliation is the cordial intercourse developed between the engineering societies. During 1916-17 the A.S.M.E. Section held three joint meetings with The Franklin Institute and one with the American Society of Heating and Ventilating Engineers, while on May 11 at a dinner given to the speaker of the evening prior to the meeting by the local committee, the Section had as guests the chairman of nearly every engineering society represented in Philadelphia.

The subjects of the meetings we have held and the speakers are as follows: The Development of Our Fleet, by Wm. L. Cathcart, Mem.Am.Soc.M.E.; Aeroplane Engines, by C. E. Lucke, Mem.Am.Soc.M.E.; The Cooling of Water for Power Plant Purposes, by C. C. Thomas, Mem.Am.Soc.M.E.; Coke Ovens and Their By-Products, by C. J. Ramsberg; Design, Construction and Equipment of a Modern Military Aeroplane, by J. C. Hunsaker; District Heating, by Walter J. Kline; The Recent Development of the V-Notch Weir Measurement, by D. R. Yarnall, Mem.Am.Soc.M.E.; and Engineering of Men, by Willard Behan.

During the year the Proceedings of the Engineers' Club of Philadelphia has been developed until it has now become quite a pretentious journal. Each of the national societies is given a large page in each issue of the publication, and in that way members of all societies affiliated with the Club are made acquainted regularly with the proceedings of all engineering meetings held in Philadelphia.

Emmett B. Carter,
Section Chairman.

PROVIDENCE

There exists at Providence a situation different from any other local center of the Society's activities. There is no regularly organized Section of the A.S.M.E. in the city, but the functions of such a section are accomplished for the Providence members of the A.S.M.E. through the affiliation of the Society with the Providence Engineering Society. The local society has made considerable progress during the past year, first by securing adequate and permanent quarters and second, through the sub-division of the organization into sections under the following headings: Fire Prevention and Fire Protection, Machine Shop, Designing and Drafting, Efficiency, Structural Engineering, Chemical, Power, Municipal, Highway and Water Supply, Industrial and Technical Education, Student, and Municipal Engineering.

Each section held meetings monthly at which papers on suitable technical topics were presented and discussed, and it is felt that great benefit was derived by the members attending.

The general meetings of the society were held monthly and included in their programs such speakers as Dr. Miller Reese Hutchison, Prof. William S. Franklin, Dr. Ira N. Hollis, Mr. George H. Pegram, Mr. Harold W. Buck, Prof. Fred H. Newell, Mr. M. Marcel Knecht, University of Nancy, France, and Professor Von Hecke, University of Louvain, Belgium.

Letters were sent out this spring inviting other local engineering organizations and branches of the national societies to coöperate with the society for mutual advantage. The cordial way in which these invitations were received gives promise of closer relations in the future.

J. Ansel Brooks,
President.

ST. LOUIS

Dominating all of the activities of the St. Louis Section was the idea of arousing in the members a greater interest for subjects not related to professional work. Although conditions were not entirely favorable for carrying through such a program, the results obtained encourage further efforts in this direction.

During the season 1916-17 three Section meetings were held, besides four joint meetings with the Engineers' Club of St. Louis. In pursuance of this program the meetings were of a social character with a lecture treating more the human side of engineering or industrial life, while the joint meetings with the Engineers' Club were devoted to more strictly technical subjects.

The average attendance ran between 40 and 45 members, the attendance at the joint meetings being considerably higher. The larger turnout of our members at the Section meetings indicated a strong preference for non-technical affairs. The supper preceding the meeting proved an attraction and will be retained during the coming year. As a result of a canvass among our members it was decided to hold one such Section meeting every month, on a Friday evening.

Of the technical papers presented during the season, one on standardized boiler construction and another on Diesel engines brought out most discussion.

No extensive plans have as yet been decided upon for the activities of the coming year, except that a special effort is to be made to increase our membership. There is a growing feeling that more attention should be paid to the subjects touching upon the human side of the engineer's work. Considerable impetus would be given to such a movement if articles or papers on such subjects were published regularly.

H. R. Setz,
Section Chairman.

WORCESTER

The season for the Section opened with the excursion to New London to visit the United States Naval Submarine Base, and also to inspect the plant of the Electric Boat Company. Many made the trip in automobiles, in addition to a good-sized delegation which went by special train from Worcester to New London.

The first meeting of the Section was held on November 14, 1916. President Jacobus was present, and his remarks concerning the activities and growth of the Society, which he illustrated by means of lantern slides, were thoroughly appreciated. Mr. Charles G. Washburn spoke on the Origin and Development of Leading Worcester Industries. It would be difficult to find one more qualified to speak on this subject than Mr. Washburn, and it was a privilege to hear from an authority the contributions which have emanated from Worcester and the vicinity—contributions to be classified as advancing the art of mechanical engineering.

The second meeting of the season was held on February 8, 1917, when Mr. Charles H. Norton, chief engineer of the Norton Grinding Co., spoke on the Introduction of Cylindrical Grinding and Worcester's Part in the Development of the Art.

The Secretary of the Society, Mr. Calvin W. Rice, was also present at this meeting and spoke on the affairs of the Society in general, and particularly upon the constructive work which was being accomplished under the presidency of Dr. Hollis.

The annual meeting was held on June 5, at which the officers for the ensuing year were elected. The delegates from Worcester who attended the annual Spring Meeting of the Society in Cincinnati were all present and told of the success which attended the efforts of the Cincinnati Section in conjunction with the Cincinnati members of the National Machine Tool Builders' Association. At this meeting announcement was also made that the Council had accepted the invitation of the citizens of Worcester to hold the 1918 Spring Meeting there. This announcement was received with enthusiasm. President Hollis addressed the meeting on Engineering Problems Relating to the War. His remarks were extremely interesting and an enthusiastic general discussion followed.

The last meeting of the season was held on June 28. By courtesy of *Machinery*, their motion-picture film representing the manufacture of 9.2-in. howitzer shells was shown. A portion of the film prepared by the Cincinnati Section, showing incidents connected with Spring Meeting, was also shown.

Interest in the work of the Society was well maintained during the winter months; the membership has increased through the activities of the Worcester Section, and there is every indication of a successful coming season.

George I. Rockwood,
Section Chairman.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER OCTOBER 10, 1917

THE American Society of Mechanical Engineers is an organization for mutual service of over 8,200 engineers and associates coöperating with engineers. The membership of the Society comprises Honorary Members, Members, Associates, Associate-Members and Juniors, all elected by ballot of the Council. Application for membership is made on a regular form furnished by the Secretary which provides for a statement of the standing and professional experience of the applicant and requires references from voting members personally acquainted with the applicant. The requirements for admission to the various grades will be furnished upon request.

Below is the list of candidates who have filed applications for membership since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, and those in the third under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by October 10, 1917, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about November 15, 1917.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be somewhat slower than under normal conditions. The first step in the consideration of an application is taken by the Membership Committee, and this committee is composed of busy men, with fewer opportunities to meet together in these strenuous times.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE MEMBER

Alabama

GARY, HARTWELL H., Superintendent, Ingalls Iron Works Co., Birmingham

Arizona

LEGRAND, CHARLES, Consulting Engineer, Phelps Dodge Corp., Douglas

California

ADAMSON, ARTHUR R., Assistant General Superintendent, Baker Iron Works, Los Angeles
BURNHAM, CHARLES, Superintendent and Manager, Burnham Basket Co., Los Angeles
MALONEY, GEORGE B., Chief Engineer, Associated Pipe Line Co., San Francisco
PIKE, ROBERT D., Chemical Engineer, San Francisco
THOMPSON, NELSON W., Chief Engineer, Simplex Refining Co., San Francisco

Colorado

WOOD, FRANKLIN P., Engineer, Franklin P. Wood & Co., Trinidad

Connecticut

BEDWORTH, ARTHUR H., Plant Engineer, Remington Typewriter Co., Bridgeport
BEGG, THOMAS K., Mechanical Superintendent Manufacturing Departments, Bridgeport Brass Co., Bridgeport
BENTLEY, JOSEPH H., Chief Draftsman, H. E. Harris Engineering Co., Bridgeport
BLOOD, BRYANT H., General Manager, Pratt & Whitney Co., Hartford
CAHILL, ANTHONY M., Equipment and Process Engineer, Winchester Repeating Arms Co., New Haven
CHERRY, JOHN D., Sales Manager, The Roto Co., Hartford
KRUCKLIN, WALTER, Tool Designer, Draftsman, Remington Arms U. M. C. Co., Bridgeport
WHEELER, CHARLES A., Professor and Engineer, Connecticut Agricultural College, Storrs
WHITNEY, ELMAR H., Assistant Wage Rate Supervisor, Remington Arms & Ammunition Co., Bridgeport

District of Columbia

LANDVOIGT, THOMAS E., Acting Heating, Ventilating and Sanitary Engineer, District of Columbia, Washington

Georgia

COVERDALE, E. J., Atlanta
HOLTZCLAW, BENJAMIN W., Chief Engineer, J. S. Schofield's Sons Co., Macon
LINDLEY, HARRY E., Chief Draftsman, L. W. Robert, Jr., Engineer, Atlanta

Illinois

BOSE, KUMUDINI K., Draftsman, Mechanical Department, Armour & Co., Chicago
BURR, ELLIS M., President, The Burr Co., Champaign
DEAN, RAYMOND S., Sales Engineer, Manning, Maxwell & Moore, Chicago
DREXELIUS, H. COREY, Designer of Automobile Machinery, Elgin National Watch Co., Elgin
GERARD, FRANKLIN B., General Superintendent, German-American Portland Cement Works, La Salle
HASKINS, HAROLD L., Engineer, International Harvester Co., Chicago
HOEFER, C. A., President, Hoefer Manufacturing Co., Freeport
JONES, DAVID J., Mechanical Inspector, Illinois Central Railroad Co., Chicago
SORENSEN, CLAUDE S., Special Machine Design, Western Electric Co., Chicago

Indiana

Member's Pin Found

A member's catch pin has been found in New York City. It is being held in the Society's offices and upon identification will be returned to owner.

ROLL OF HONOR

To the lists already published of those members of the Society who have enlisted in the national service is added the following supplement:

Baird, Lyman S., First Lieutenant, Aviation Section, Signal Corps, U. S. A.

Baldwin, Bert L., Major, Officers' Reserve Corps.

Belcher, P. W., First Lieutenant, Engineer Officers' Reserve Corps.

Boardman, A. Jay, Captain, Ordnance Department, Officers' Reserve Corps.

Brayton, Harold M., First Lieutenant, Ordnance Department, Officers' Reserve Corps.

Briggs, Leroy E., Captain, Ordnance Department, Officers' Reserve Corps.*

Brill, George M., Major, Engineer Officers' Reserve Corps.

Byron, Leroy T., Chief Petty Officer, U. S. Naval Reserve Force, Brooklyn Navy Yard.

Case, Milo M., Captain, Engineer Officers' Reserve Corps.

Conant, William S., Ordnance Department, Officers' Reserve Corps.

Cronemeyer, Henry C., First Lieutenant, Engineer Officers' Reserve Corps.

Dalley, Park R., Captain, Engineer Section, Officers' Reserve Corps.

Diemer, Hugo, Major, Ordnance Section, Officers' Reserve Corps.

Dodd, Willard, Lieutenant, Junior Grade, U. S. Naval Reserve Force, Naval Training Station, Great Lakes, Ill.

Eichelsberg, Mark A., Ordnance Department, Officers' Reserve Corps.*

Farrell, Morgan G., First Lieutenant, Engineer Officers' Reserve Corps.

Field, Crosby, Lieutenant, Ordnance Department, U. S. A. Inspection Division.

Gilbert, Huntly H., Captain, Ordnance Department, Officers' Reserve Corps.

Gillam, William H., First Lieutenant, Officers' Reserve Corps, Ordnance Department.*

Greenwald, Louis, Electrician Sergeant, Fort Totten, N. Y.

Guiteras, Julian G., Lieutenant, Company I, P. O. Battalion, Fort Leavenworth, Kansas.

Hazlehurst, James N., Major, Engineer Section, Officers' Reserve Corps.

Henley, Erl K., Lieutenant, Junior Grade, United States Naval Reserve Force.

Hirsch, Gustav, Major, Signal Officers' Reserve Corps.

Jackson, John R., Captain, Ordnance Department, Officers' Reserve Corps.

Jellum, Kristen, Second Lieutenant, Engineer Officers' Reserve Corps.

Kaelin, Charles G., Captain, Ordnance Department, Officers' Reserve Corps.*

Keep, Henry, Major, Engineer Officers' Reserve Corps.

Keller, Parry, First Lieutenant, Ordnance Department, Officers' Reserve Corps.

Kenrick, Alfred E., First Regiment, Mass. Engineers' National Guard.

Knerr, Lewis E., First Lieutenant, Engineer Officers' Reserve Corps.

Knoebel, Carl B., Company F, 1st Infantry, Texas National Guard.

Kunze, Edward J., Captain, Quartermaster Department, Office Reserve Corps.

Lent, Leon B., Captain, Aviation Section of Signal Corps, active duty Curtiss Aeroplane Co., Buffalo, N. Y.

Lyman, Elihu E., Captain, Ordnance Department, Officers' Reserve Corps, Frankford Arsenal.

Lynch, Frank J., Aviation Section, Signal Officers' Reserve Corps, Texas University.

Lynde, Charles C., First Lieutenant, Engineer Officers' Reserve Corps.

McClintock, Allen P., First Lieutenant, Ordnance Section, Officers' Reserve Corps.

MacGill, Charles F., Ordnance Department, Officers' Reserve Corps.*

Martin, Kingsley G., Captain, Officers' Reserve Corps, Motor Transport Service.

Mosman, Ernest, First Lieutenant, Ordnance Department, Officers' Reserve Corps.

Rettig, George P., Office of Army Inspector, Signal Service at Large as Inspector of Airplanes and Airplane Engines.

Sees, Joseph S., Captain of Ordnance, Officers' Reserve Corps, Assistant Superintendent of Small Arms Ammunition, Frankford Arsenal.

Selfridge, Samuel W., Second Lieutenant, Field Artillery, Officers' Reserve Corps.

Selser, T. W., First Lieutenant, Engineer Officers' Reserve Corps.*

Scott, Rossiter S., Captain, Engineer Officers' Reserve Corps.

Slade, Arthur J., Aeronautical Division of the Signal Corps.

Swift, Harley L., Lieutenant, Officers' Reserve Corps.

Tag, Walter, Ordnance Reserve Corps.

Taylor, William T., Captain, Royal Flying Corps.

Tilson, Howard, Captain, Ordnance Department, Officers' Reserve Corps.

Trego, A. C., Lieutenant, Springfield Armory, Springfield, Mass.

Vogt, Clarence W., First Lieutenant, Ordnance Department, Officers' Reserve Corps.

Walker, Perley F., Major, 314th Regiment, National Army, Fort Riley, Kan.

Webster, Lawrence B., Captain, Ordnance Department, Inspection Division, Officers' Reserve Corps.

Whipple, C. Earl, Captain, Engineer Officers' Reserve Corps.

Whitlock, Elliott H., Eng. Co., 9th P.T. Regiment, Ft. Leavenworth, Kan.

Williams, Fay B., First Lieutenant, Ordnance Department, Officers' Reserve Corps.

Williams, Silas, First Lieutenant, Ordnance Department, Officers' Reserve Corps.

---

*Acceptance of commission pending at date of latest list from War Department.

NECROLOGY

FRANK LEWIS BIGELOW

Frank L. Bigelow was born in New Haven on September 21, 1862. He was educated in New Haven, attending Hopkins Grammar School and later Yale University. He was graduated from Sheffield Scientific School with the class of 1881, having specialized in dynamical engineering.

Upon graduation he entered the shops of The Bigelow Co., manufacturers of fire- and water-tube boilers. He worked in the shops for about two years and in 1883 he was made secretary of the company. Later Mr. Bigelow succeeded his father as president. He was also president of the National Pipe Bending Co. for the last ten years of his life. He was a director in the Merchants and National Savings Banks and in the New Haven Water Co.

Mr. Bigelow was a member of the American Society of Naval Engineers, a member of the executive committee of the Yale Engineering Association, and was after graduation continuously the secretary of his class, 1881 (Sheffield). He was also president of the Yale Press Association.

He became a member of the Society in 1887. He died in New Haven on June 20, 1917.

CHARLES EUGENE WILLEY DOW

Charles E. W. Dow was born in Manchester, N. H., on April 25, 1859. He was educated in the public schools of that city, and commenced his professional work there by the acceptance of a position as draftsman with the Amoskeag Mfg. Co.

He held successively the positions of chief draftsman with the Brown & Sharpe Mfg. Co., Providence, R. I.; mechanical engineer with the Hotchkiss Ordnance Co., also of Providence; agent for the Metallic Drawing Roll Co., Indian Orchard, Mass., and manager of the American Bolt Co., Lowell, Mass.

Mr. Dow was widely known in the textile industry of this country, having been closely associated with these manufacturers in humidification work and air conditioning for about fourteen years.

At the time of his death he was consulting engineer and vice-president of the Elbert Clarke Co., engineers, of Rochester, N. Y.

He was a member of the New England Cotton Manufacturers' Association. He became a member of the Society in 1911. He died on June 16, 1917.

CHARLES FITZGERALD

Charles Fitzgerald was born in Monroe, N. Y., on October 1, 1859. He received his early business training and experience with the Ramapo Car Wheel Co., in whose employ he worked from 1879 to 1882, leaving that firm to accept a position with John Roach & Sons, Chester, Pa.

His next position was with the American Ship Building Co., Philadelphia, where he was the foreman in charge of the erection of marine engines. From 1885 to 1889 he worked with Robert Wetherill & Co. as outside erection engineer. He was next associated with the Citizens Traction Railway Co. as chief engineer, and later as general superintendent of that company and the Consolidated Traction Co., Pittsburgh, Pa. In 1902 he accepted the position of mechanical engineer with the firm of Booth & Flinn, Pittsburgh. In 1906 he became general manager of the Brazilian Dredging Co., Brazil, South America. At the time of his death he was assistant to the president of the Pittsburgh Valve Foundry & Construction Co.

Mr. Fitzgerald became a member of the Society in 1912. He was also a member of the Engineers' Society of Western Pennsylvania. He died on June 2, 1917.

ALBERT FREDERICK GANZ

Albert Frederick Ganz was born in Elberfeld, Germany, April 25, 1872, and came to this country with his parents in 1881. After attending private and public schools he entered the College of the City of New York in 1886, and completed the first year's work in the mechanical course. For the next four years he was employed in the electrical works of Bergmann & Company, New York City, and of the Edison General Electric Company, Schenectady. During this time he attended the Cooper Union Night School. He entered Stevens Institute of Technology as a member of the sophomore class in 1892 and was graduated in 1895 with the degree of Mechanical Engineer. Immediately after graduation he was appointed instructor in applied electricity; two years later he was advanced to the position of assistant professor of applied electricity and physics; and in 1902 he was appointed professor of electrical engineering and head of the department. With the appointment of class deans in 1908, he became dean of the senior class. The period of Professor Ganz's connection with Stevens—1895 to the present—coincided with the phenomenal advance in the theory and practice of electrical engineering, and it is mainly due to his study and efforts toward improvement that the electrical course was kept abreast of the times and that so many graduates of Stevens have been fitted for responsible positions in the electrical field.

Professor Ganz was widely known in the engineering world, having made many commercial and scientific tests and investigations. He had made a special study of methods for mitigating corrosion of underground structures by electrolysis and was a national authority on this subject. He contributed many valuable scientific papers to technical societies and journals.

In Professor Ganz's death his associates and former pupils have lost a friend whose helpfulness could always be depended on. The great care which he took in reaching conclusions, coupled with his unquestioned integrity, commanded universal respect for his judgment in engineering matters. His untiring energy and intense love of his work were an inspiration to all.

Professor Ganz was a fellow of the American Institute of Electrical Engineers and of the American Association for the Advancement of Science, and a member of the following societies: The American Society of Mechanical Engineers, American Gas Institute, American Electrochemical Society, The Society for the Promotion of Engineering Education, Illuminating Engineering Society, American Water Works Association, National Electric Light Association, and past president of the New York Electrical Society. He was also a member of the Hoboken Board of Trade, the Engineers' Club and the German Liederkranz of New York, and of the Tau Beta Pi fraternity.

Professor Ganz became a member of the Society in 1910. He died on July 27, 1917.

CASIMIR von PHILP

Casimir von Philp was born in Stockholm, Sweden, in 1853. After having finished his preliminary education, he entered the Stockholm Institute of Technology and in due time was graduated therefrom.

His first position was in the office of W. Wennstrom, in Oerebro, Sweden, but he did not remain there long, and after holding several other positions finally engaged in consulting engineering work. He saw, however, that the United States offered a much broader opportunity, and in 1880 came here with his family.

Shortly after his arrival in America he obtained a position with E. D. Leavitt, of Boston, Mass., and while in his employ had complete charge of several important undertakings, among them being the sewage pumping installation in Boston and the large pumping machinery constructed for the Calumet mines.

After several years in Mr. Leavitt's employ, Mr. von Philp obtained the position of chief engineer with the Burden Iron Company, of Troy, N. Y. In 1890 he became the chief engineer of the Bethlehem Steel Co.

After sixteen years Mr. von Philp severed his connection with the Bethlehem Steel Co. in order to devote all his efforts to his inventions in the field of presses. In 1908, however, he returned to the Bethlehem concern as manager of the machine department, a post which he occupied up to the time of his death.

Mr. von Philp was a member of the American Society of Swedish Engineers, American Society of Engineers, and of The Committee of Fifty, organized to erect a memorial to John Ericsson in Washington, D. C. He was actively interested in the work of this committee and was instrumental in obtaining a donation of \$500 to the funds of the committee from the Bethlehem Steel Company.

He became a member of the Society in 1890. He died on July 4, 1917.

HENRY SOUTHER

Major Henry Souther, senior officer, aircraft engineering division, aviation section, Signal Corps, U. S. A., and vice-president Henry Souther Engineering Corporation, Hartford, Conn., died August 15 in the post hospital at Fortress Monroe, Va., following an operation. He was born at Boston in 1865 and was graduated in 1887 from the Massachusetts Institute of Technology, where he specialized in mining and metallurgical subjects. After studying abroad the manufacturing methods and processes employed in the German iron and steel industry, he entered in 1888 the employ of the Pennsylvania Steel Co., at Steelton, and was made assistant foreman the following year. He was engineer of tests for the company from 1890 to 1893, resigning to become engineer of tests for the Pope Mfg. Co., a position which he held for six years. At the Pope works he organized the first testing plant ever installed, it is believed, by a consumer of steel for the scientific testing of materials and developed the use of cold-drawn tubing for bicycles and automobiles.

When the Pope organization was dissolved in 1899 he engaged in business as an independent consulting engineer and established a metallurgical and testing laboratory and did consulting work for the automobile industry. He was president and treasurer of the Henry Souther Engineering Corporation from 1899 to 1909 and became president in 1911, but of late years was not very active in the management of that organization. He was vice-president and general manager of the Ferro Machine & Foundry Co., Cleveland, from 1915 to the outbreak of the war. Latterly he had charge of the aircraft development of the army and created a corps for the inspection of aircraft.

He became a member of The American Society of Mechanical Engineers in 1894. He was prominent in the Association of Licensed Automobile Manufacturers, was a founder member of what is now the Society of Automotive Engineers, and had much to do with the development of the iron and steel standards of that body. He was president of that society in

Henry Souther

1911 and served as chairman of the standards committee for a number of years. In 1915 he was made a life member in recognition of this work.

DANIEL A. WIGHTMAN

Daniel A. Wightman was born in East Greenwich, R. I., on August 7, 1846. He was éducated in the schools of East Greenwich, attending for a time the academy there. Having learned the carpenter's trade, he worked at that while taking up the study of drawing at an evening school in Providence, R. I.

About 1870 he took a position as draftsman with the Rhode Island Locomotive Works. He soon became chief draftsman there and for a time was virtually superintendent of the shops. In 1876 he accepted the position of superintendent with the Pittsburgh Locomotive Works and was with them until he retired in 1902, then holding the position of general manager. While at Pittsburgh Mr. Wightman rebuilt the plant and made many improvements in locomotive design, the most important of which was the introduction of power flanging in place of the hand method for heavy boiler sheets. After retiring in 1902 he did some consulting work for the Baltimore & Ohio and Lehigh Valley railroads in connection with locomotive repair shops.

He was a member of the American Railway Master Mechanics' Association. He became a member of the Society in 1884. He died in Warren, R. I., on July 6, 1917.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

GOVERNMENT REQUESTS

The Society has been asked to make suggestions of men for the following positions with the Government. Further information will be given on request. Non-members of the Society having the qualifications may avail themselves of these notices by enclosing with their reply a personal introduction to the Society.

AERONAUTICAL MECHANICAL ENGINEER. Age, 25 to 40 preferred. Salary, up to $2750. Qualifications: Technical education with degree of M.E. or C. E. or its equivalent and good practical experience with first-class manufacturing concerns. Must be able to handle and direct men. Duties: In Washington, or as district manager of the various branches of the Inspection service; or at one of the various factories where airplanes and engines are being manufactured. 2059 (Serial No. 31).

AERONAUTICAL ENGINEER. Age, 25 to 40 preferred. Salary, up to $3600. Qualifications: Familiarity with complete design of an aeroplane and the ability to carry through new designs in same. Should be able to direct and handle men. Duties: In Washington, or at one of the various airplane factories where airplanes are being made, to act as Senior Inspector or to act as advisory engineer to such inspection force. 2059 (Serial No. 32).

YOUNG ENGINEERS of high grade, experienced in the manufacture of small arms, small-arms ammunition, or similar repetition work, such as the making of typewriters, adding machines and sewing machines, for duty in the Small Arms Division of the Ordnance Department; and also for inspection duty at the various ammunition factories which will supply small arms and small-arms ammunition for the Government. 1108.

MECHANICAL ENGINEER of experience with electrical auxiliary machinery and with hydraulic-electric machinery, of proved ability, to act in consulting capacity in mechanical matters affecting ship design. Salary commensurate with qualifications desired cannot be paid, but nominal salary will be paid and man of high ability who can volunteer balance of services is desired. 1165.

HEATING AND VENTILATING ENGINEER AND DRAFTSMAN.
ELECTRICAL ENGINEER.
MECHANICAL ENGINEER.
Under Civil Service Commission, September 4. Request Form 2118, Treasury Department, Washington. Pending establishment of eligible list temporary appointments will be made, in office of Supervising Architect. Majority of engineers appointed are versed in heating and ventilating work or in electrical work only, but it is planned to include design of entire mechanical equipment of large buildings. 2074.

EDITORIAL ASSISTANT. Position covers the technical review and editing of manuscripts to be published as bulletins of one of the state departments, shorter papers for the trade and scientific journals, preparation of semi-popular articles on the work of the laboratory, news items for the press and assembling of material for monthly and annual reports. Entrance salary, $1500-$2000. 2128.

INSPECTORS AND ASSISTANT INSPECTORS OF ORDNANCE EQUIPMENT. Subclassification of this examination will be for inspectors and assistant inspectors of aluminum and mess equipment. These items comprise such articles as meat cans, aluminum and steel knives, forks, and spoons, plates and similar articles. Their duties will be to supervise the inspection of these items, both in process of manufacture and when ready for delivery. Also, they will have charge of operation of vouchers and other papers by which the contractor receives payment for the articles supplied. These positions are Civil Service appointments and will pay from $1000 to $2000 per annum. Applicants must have completed a course in a college or university of recognized standing and have at least one year's experience in the lines of merchandise they purpose to inspect, or they must have a high-school education or its equivalent and in addition at least four years' experience in these lines of work or in related lines. Applicants should be at least 25 years of age. No person who is liable to call in the first draft quota can be considered for this position. 2117.

MECHANICAL ENGINEERS, ORDNANCE DEPARTMENT, available as Reserve Ordnance Officers, principally with the grade of 1st Lieutenant. Men should be, probably, between 31 and 35 years of age, and graduate engineers who have had experience in machine design. 2072.

MECHANICAL ENGINEER, QUARTERMASTER'S DEPARTMENT, salary $3,000. Qualifications: Training and experience in the design and construction of central heating plants and central power plants, together with general knowledge of mechanical engineering and office administration. Appointments to this position subject to certification from U. S. Civil Service Commission. 2099.

PRODUCTION SECTION, CARRIAGE DIVISION, ORDNANCE DEPARTMENT. Positions: First Lieutenant, Ordnance Officers' Reserve Corps. Salary, $2,000 per year plus $500 (regular army allowance) and traveling expenses. Age, 27 to 40 years. Duties: Positions under both calls will be in Washington or in field work at various factories in the United States. They will be for the duration of the war. Applicants must be physically sound.

Qualifications: Training and several years' experience in machine-shop practice and production. Must be capable of investigating plants to determine capacity for orders and to investigate causes of failures of contractors to make promised deliveries. 2085 (Call No. 36).

Qualifications: Training and experience in purchasing machine tools and equipment, steel castings, forgings, and other raw material and supplies used in machine construction, and general knowledge of them. 2085 (Call No. 37).

For the following positions, Nos. 2118, 2119 and 2120, letters showing qualifications should be sent to the Secretary. Further information cannot be given at this time.

SUPERINTENDENT OF WOOD-WORKING SHOP. To be familiar with the operation of modern planing-mill machinery such as re saws, rip saws, molders, etc., as required to manufacture wood parts of airplanes and pontoons. Also to be familiar with the construction of life boats or racing shells, or working boats, or airplanes and pontoons. To be of sufficient executive experience to warrant confidence in his ability to build up and control a force of 200 men. 2118.

SUPERINTENDENT OF THE METAL SHOP. To be familiar with general sheet-metal work, including brazing, and welding by the autogenous and spot-welding processes; and with the design of dies for, and operation of, punch presses. To be familiar with general machine-shop and tool-room practice. To have some little experience with manufacturing automatics. To have rudimentary knowledge of the heat treatment of steel. 2119.

ENGINEER OF EXPERIMENTS, OR RESEARCH ENGINEER. To have an engineering education, experience as engineer of tests or research, and an understanding of the value of time. 2120.

POSITIONS AVAILABLE

In forwarding applications, stamps should be enclosed for transmittal to advertisers; applications for non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society. Copy for notices must be in hand by the 15th of the month.

TOOL DESIGNER who is resourceful and can follow work through to completion. Technical man with practical shop experience. Location Connecticut. 185.

SALES ENGINEERS. It is desirable that applicants be young men between 25 and 30 years of age, preferably M. E. graduates of some approved engineering college, and of good appearance. They will be expected to undergo a period of probation and training in various offices of company for responsible and higher positions in sales work. If a call cannot be made, application may be made by letter in applicant's own handwriting, stating age, education, previous business training, if any, salary desired, etc. Location New York. 205.

STRICTLY HIGH-CLASS MAN who can conduct classes and give lectures covering automobile subjects for a large public institution

[illegible] Middle Northwest. Must be a technical graduate with practical experience [illegible] field of work. 121.

ELECTRICAL ENGINEER possessing extensive experience with electrolytic plants for producing oxygen and hydrogen, wanted by New York concern. 811.

MACHINERY DESIGNER in turbine department of large electric company. Location Massachusetts. 894.

MASTER MECHANIC for lead-smelting plant operating blast furnace and concentrating mill. Must be man of strong personality, capable of handling varied classes of mechanics. Give full details of education and experience. Location Utah. 906.

TECHNICAL ENGINEER with experience in steam engineering to act as assistant operating engineer in large industrial plant located near Chicago. State age, experience and salary expected. 938.

SALESMEN on machine tools to represent large New York exporting corporation in China, Australia and South Africa. 964.

DESIGNERS. Men experienced in steam-engine and turbine work preferred. 967.

DRAFTSMAN familiar with power-house work, installation of equipment, piping, etc., and competent to work out different problems involved from general outline without need of more or less constant supervision. Salary $25 to $28 per week. Location New York. 969.

DRAFTSMEN AND DESIGNERS. Experienced men with some knowledge of valves and fittings; good future with large concern. State experience in full, salary expected and references. Confidential. 1002.

DRAFTSMAN for patent office drawings. Salary $25 to $35. Location New York. 1022.

YOUNG ORGANIZING ENGINEERS for intensive management work, in general manager's office of one of the large units of the rubber industry. Opportunity decidedly promising. State initial salary expected, age, experience, qualifications, etc. Please give full, character-indicating letter. Location Middle West. 1047.

MECHANICAL LABORATORY ASSISTANT for technical school in Greater New York. Recent mechanical engineering graduate with one or more years of practical work since graduation. Single man about twenty-five years of age preferred. Position offers exceptional opportunity for advancement. State age, education, experience, present employment and references. Enclose photograph with application. Salary $1200. 1060.

ELECTRICAL TESTER wanted immediately by Chicago blower manufacturer; to work as draftsman 20 per cent of time. Permanent position, with opportunity for promotion to salesman, designer or foreman. Salary $18 for first 20 weeks. Experience unnecessary. Describe education and physical condition. 1075.

DRAFTSMAN. Young engineer, preferably technical graduate, with about a year's practical experience; who could work into a good position. Salary $25 to start. Location New York. 1080.

DRAFTSMAN AND ESTIMATOR for work of varied character with large concern; good opportunity for advancement. Location New Jersey. 1104.

MECHANICAL-ENGINEERING DEPARTMENT of a Middle West state college desires applications from men suitable for the position of foreman in machine shop. The successful applicant must have had several years' actual machine-shop work and be familiar with methods of mass production and scientific management. College training desirable but not absolutely necessary. Should have had experience as foreman or assistant foreman in some successful shop, and preferably some teaching experience, although this is not absolutely necessary. Prefer a man not over 35 to 40 years of age. 1112.

DRAFTSMEN experienced in ordnance work, particularly small arms and machine guns; or experienced in complicated automatic machinery. Location Ohio. 1131.

COMBUSTION ENGINEER. Duties primarily those of efficiency work in the burning of fuel and generation of power, also in the use of power in the various departments of plant. Power plant is of 1000 hp. capacity, with extensive distributing system for air, steam and electricity. Excellent opening for a man interested in steam power-plant work. State fully qualifications, training and experience. Location New Jersey. 1133.

GRADUATE MECHANICAL ENGINEER with knowledge of theory of centrifugal machinery—preferably fans, pumps and compressors—and also thoroughly familiar with their design and methods of testing. Apply by letter. Location New York. 1140.

COMPETENT MAN, about 35 years old, to take hold of maintenance and machine repairs and general shop economics. Prefer one with a technical education and enough shop experience to understand the operation of all machine tools, and who has a full appreciation of the value of time on an operation without going into any efficiency work. Opportunity for advancement and eventually an executive position. 1166.

MECHANICAL ENGINEER. Technical graduate, several years' experience along general and mechanical lines. One conversant with industrial machine design preferred. Permanent position with large corporation. State age, college, previous experience and salary desired. Location Cleveland. 2023.

MECHANICAL DRAFTSMAN. Young college graduate preferred. General industrial-mechanical engineering work. Permanent position with large corporation. State age, college, experience if any, and salary desired. Location Cleveland. 2024.

INSTRUCTOR IN MECHANICS and strength of materials wanted by an eastern engineering school. Must have had the usual technical training in experimental laboratory work, so that he can also assist in hydraulic and steam laboratories. Good opening for the right man. State additional training and experience if any. Salary will depend on the amount of work that can be carried. 2025.

ASSISTANT PROFESSOR in sanitary engineering. Location near New York City. 2026.

AUTO REPAIR MAN familiar with Hurlbut type of truck. One-year contract. Prefer a single man. Salary $175. Location Chile, near Valparaiso. Expenses down and back. 2092.

ESTIMATOR for New York concern engaged as engineers and contractors for power plants, ventilation, steam and hot-water heating. 2103.

YOUNG MAN between the ages of 25 and 28 who is not drafted and who is interested in manufacturing work. Position will give him full control of the cost work. Salary to start, $100 per month, and depends upon the man. Applicant need not be experienced in the same line, but should have some knowledge of the line. Location New Jersey. 2109.

ASSISTANT YOUNG ENGINEER for office of consulting engineer, to assist in development of patents and inventions. Location New York. 2110.

SUPERINTENDENT for firm engaged in the japanning and enameling of automobiles. Man of executive ability and experience in lines that would fit him for taking charge of shop. Location Long Island City. 2111.

SEVERAL GOOD DRAFTSMEN who have had experience in designing machine work, in particular stoker work. 2114.

EXPERT TOOL- AND FIXTURE-DESIGNING DRAFTSMAN for line of safety valves, steam gages and similar equipment. Applicant must have sufficient education and experience to enable him to take charge of the drafting department, within a reasonable time, as chief draftsman. Location New York. 2115.

WORKS ENGINEER. Must have thorough knowledge of tool design for automatic machines and ability to plan and demonstrate operations. Duties include general supervision of tool design, tool making machine repair and plant maintenance. Salary to start $3000. Apply by letter. Location Ohio. 2116.

ASSISTANT CHEMICAL SUPERINTENDENT for plant involving a wide field, with over 1200 employees, near New York. Man must have ability to handle men. 2028.

DRAFTSMAN familiar with water-wheel equipment. Unusual opportunity in a Central Massachusetts concern. Technical graduate preferred. 2042.

JUNIOR DRAFTSMAN who can do detail work from sketches or personal instructions. Salary $15 per week. 2043.

MECHANICAL ENGINEER to take charge of engineering department. Must be thoroughly familiar with the design and operation of pulp- and paper-mill equipment. Should be competent to design buildings. A sound working knowledge of steam and electrical power-

plant design and operation is required. Good opening for a capable, energetic man. Location Hammermill Paper Co., Erie, Pa. 2044.

JUNIOR DRAFTSMAN with experience in heavy motors. Salary $125-175. Location Michigan. 2047.

DRAFTSMAN on electrical machinery for power plant layout work. Salary $150-160. 2048.

ASSISTANT CONSTRUCTION SUPERINTENDENT. Must be accustomed to handle men, lay out work, to carefully watch all details, etc., and be a good organizer. Main requisites are in connection with mechanical equipment of buildings already erected, i. e., piping, tanks, shafting, timber details, etc. Blueprints will not always show details and considerable knowledge is essential in order to carry on the field work without delay. Salary $175 to start, advancement according to ability. Give full information by mail as to age, nationality, married or single, liability to draft, references, when could report for work, etc. 2049.

INSTRUCTORS for (1) Applied Science Laboratory and in (2) Mechanics and Elementary Electricity wanted by a technical school in Brooklyn. Salary first year $1200 to $1500, according to individual. Preference given to men with mechanical or electrical engineering training and practical and teaching experience. Apply by letter only, giving full personal and experience data and recent photograph if possible. 2050.

INSTRUCTORS. Men of good personality, capable of commanding the respect and attention of the students, most of whom are college-trained men, to train U. S. Army aviators eight weeks' course. Should be capable of directing the assembling, disassembling and operation of aeronautical motors. Prefer to have college graduates who have had one or more years of practical experience and training in either aeronautical works or on engines in a motor-car works. Salary $100 to $125 per month, or more, according to experience and teaching ability. Willing to take a 1917 graduate in mechanical engineering who has specialized somewhat in gas engines, in which case would like to send him for a month of special training to an aeronautical factory and pay him $85 a month to start. 2051.

MECHANICAL AND ELECTRICAL ENGINEERS. One wanted of each. Preferably married men without children. Positions at sulphur refining factories in France. 2052.

MECHANICAL ENGINEER, age about 35, to travel in Dutch East Indies. Must have thorough knowledge of machinery, steel products and kindred lines of territory named. Export knowledge desirable but not essential. State age, experience and salary expected, also when at liberty. 2054.

YOUNG MECHANICAL ENGINEER who is industrious and capable and has had fuel-economy tests and power-plant testing, and practical experience in the construction and testing of modern Westinghouse steam turbines. Possibilities of advancement for right man. Location New Jersey. 2055.

YOUNG TECHNICAL GRADUATE in production department; one who has had some experience in manufacturing operations and understands machine tools. Position will pay from $75 to $100 per month at the beginning and future will depend upon ability. Must be energetic and not afraid of work and capable of developing executive ability. 2057.

DRAFTSMAN on a.c. or d.c. motor design. Salary about $40 per week. 2058.

RAPID DETAIL DRAFTSMAN AND DESIGNERS on hydraulic turbines, electric furnaces, gas producers, heavy machinery for steel-plant and coke-oven equipment, coal and ore-handling equipment, and complicated structural details. Location Cleveland. 2061.

SALES ENGINEER for Cleveland territory to handle power-plant equipment. Technical graduate preferred with power-plant and sales experience. 2062.

DESIGNER for tools and rapid-production devices wanted by engineering department of a munition factory. 2066.

DRAFTSMEN on mechanical-stoker work. Men familiar with boiler-room layouts, building construction or heavy-machine design acceptable. Salaries up to $30 per week to start, depending upon ability and experience. Permanent positions. Also draftsmen experienced in auxiliary marine machinery, hoisting engines, hoisting-engine design in connection with this class of machines, engine designers. Salaries up to $30 per week. Location Philadelphia. 2069.

MECHANICAL ENGINEER who has had several years' experience in the design, construction and erection of machinery, structural work, piping, etc., and preferably as many months' selling experience, for permanent position among congenial associates. Location New York City, but must be willing to go out of town whenever required. Salary $225 per month to start. 2070.

TWO TECHNICAL GRADUATES approximately 30 to 38 years of age with experience of sufficient breadth so that they would be posted on problems of manufacture in more than one line. Men who have been steadied by experience, yet ambitious to push ahead and interested in the various problems of manufacture and construction. Location Massachusetts. 2071.

CHIEF DRAFTSMAN. Location Connecticut. 2076.

INSPECTOR competent to handle structural material for firm of consulting, construction and management engineer. Location Connecticut. 2078.

ASSISTANT SUPERINTENDENT for Chicago tool manufacturer. Start at $150 per month with increase to $200. Describe education and physical condition. State number of months in previous positions, exact nature of duties and number of hours per month on each duty. 2079.

DRAFTSMAN on machine tools. Young man wanted who has had considerable experience in designing machine tools, more especially grinders. Salary $25 at least, depending upon ability. Location Boston. 2083.

EXPERIENCED TIME-STUDY MAN familiar with the production of small interchangeable parts, for manufacturing plant in Philadelphia. Position will lead to one of responsibility. 2084.

MECHANICAL ENGINEERS experienced in jigs, dies, gages and fixture work; also in mass production of small articles where drawing and other press work has been the principal occupation. Location New York. 2086.

PRODUCTION PLANNING MAN. One with considerable experience in such work and who is ambitious and capable of getting results. Work will consist of planning the production of ball bearings through the entire shop, routing of the material, etc. Prefer a man not subject to military draft and upon whom considerable authority can be placed. Location Connecticut. 2088.

EFFICIENCY TIME-STUDY MAN who has had some experience along these lines, and, if possible, is acquainted with the manufacture of small parts in automatic machinery and grinding machinery. Location Connecticut. 2089.

EMPLOYMENT DEPARTMENT HEAD. Man wanted to take charge who has had some experience and who understands all the different phases of hiring and keeping help. Location Connecticut. 2090.

PRODUCTION MANAGER for factories located at various places, but with headquarters at New York office. Man between 35 and 40. Salary depends entirely upon man. Write asking for appointment, giving brief record of education and experience. 2091.

INSTRUCTORS in steam-engineering laboratory in training government recruits. $30 a week, hours 9-11 a. m., 1-3:30 p. m. 2093.

INSTRUCTORS in machine design, with some laboratory work. Location Brooklyn, N. Y. 2094.

ASSISTANT IN STEAM LABORATORY. Salary about $1,200. Previous teaching experience not necessary. Location Brooklyn N. Y. 2095.

TECHNICAL GRADUATE wanted as instructor in mechanical engineering, tracing, machine design, gas engines and machine shops for southern university. In application state age, education, experience, references and salary desired. 2098.

AUTOMOBILE ENGINEER capable of designing pleasure cars and motor trucks. Experience with Russian requirements desired. Must be good correspondent. Middle-aged man preferred. In first letter state age, education, experience in detail, salary expected, also when at liberty. 2104.

A LARGE GROWING PAPER MANUFACTURING CORPORATION can offer excellent opportunities for interesting and effective work to two young college graduates with tact, initiative, ability and common sense. Non-graduates with two or more years of manufacturing experience will be considered; men wanted who can develop and who have the vision to see and grasp an opportunity. Fair living salary at start. Give complete information. Men will not be engaged until the right ones are found.

EMPLOYMENT MANAGER in plant employing 600 men in the [illegible]. Exceptional opportunity for experienced men. 212[illegible]

PRODUCTION MANAGER in organization operating under a pro[illegible] management, under the production manager come all questions of planning, scheduling and routing. Man at least 30 [illegible] who has had a technical training and some years' experi[illegible] modern methods of management, and whose personality will [illegible] to readily control quite a large force of people. Po[illegible] [illegible] opportunity and pay such salary as will attract [illegible]. Location Middle West. 2123.

DRAFTSMAN. Weekly salary of \$20. Apply by letter to Employ[ment] Department, Maxim Munitions Corporation. Location W[atertown], N. Y. 2124.

MAN to take charge of a stationary engineering department, and who has had actual operating experience in addition to a technical training. Opening should be desirable for type of man interested in educational work. Prompt action necessary, because decision will be made in [short] time. 2126.

YOUNG SALESMAN in the Boston or Philadelphia districts. Guarantee income and extended commission on sales. Applicant should have an education, good appearance, some advertising or artistic ability preferred. 2127.

STRUCTURAL STEEL DRAFTSMAN experienced in powdered coal plants, industrial plants, power houses, layouts, etc. 1011.

ASSISTANT SUPERINTENDENT for maintenance and construction work in chemical factory. Technical graduate desired. Location St. Louis. Salary \$1,500. 1149.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be in hand by the 15th of the month, and the form of the notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

PRODUCTION SUPERINTENDENT. American, age 36, married. Twenty years' practical experience in interchangeable parts manufacture, such as locomotives, road rollers, traction engines, conveyor machinery, rock crushers, marine engines, and munitions. Has had wide experience as sales engineer and has successfully held positions as machine shop foreman, general foreman, superintendent. Desires position with Eastern firm, preferably Philadelphia or vicinity. Best of references. I-297.

CONSTRUCTION SUPERINTENDENT. Japanese, aged 42. Fourteen years' practical experience in mechanical and electrical installation work as foreman, inspector of railroad cars and electrical building constructor. At present employed in one of the largest traction companies as power-plant and sub-station designer. I-298.

SUPERINTENDENT. General foreman, who has had seventeen years' experience in mechanical and executive positions in interchangeable manufacturing, desires position. I-299.

MECHANICAL ENGINEER broadly experienced in design and management of power plants, factory maintenance and development of methods and processes, desires position where such experience along with executive ability and chemical training will be of value. At present employed. I-300.

CHIEF DRAFTSMAN OR ASSISTANT ENGINEER, now chief draftsman of a staff of twelve, totaling a monthly payroll of over \$2000, desires change of location. Specialty, large industrial plants, as mining and smelting, covering all branches of engineering. Salary \$250 a month. Age 36. American born, single. Associate-member A S M E. I-301.

WORKS MANAGER OR CHIEF ENGINEER. Technical graduate, M.E., experienced in superintendence, management, and in shop planning and intensive production of duplicate parts. Salary \$3500-\$4000, depending upon nature of work. Prefers location near New York or Philadelphia, but will consider any good proposition located in the United States. I-302.

CHIEF ENGINEER AND RESEARCH EXPERT with 16 years' practical training in oil and gas-engine development work. Broad experience in the fine points of both the technical and business side of engineering, with special aptitude for research work and the perfection of new ideas. Thoroughly competent to handle men and to take charge of the development, design and supervision of construction of either marine or stationary internal combustion engines. At present employed. Best of references. I-303.

MECHANICAL ENGINEER. M. I. T. graduate, age 23, married. Desires a position with a future, where work and responsibility will count. Mechanical and electrical drafting room experience. At present employed. Location in the East preferred. I-304.

ENGINEERING EXECUTIVE. Technical graduate, age 29, married. Seven years' experience in designing, manufacturing and industrial plant construction. Wants responsible position. At present employed as mechanical engineer for eastern steel foundry. I-305.

STEAM AND COMBUSTION ENGINEER. Technical graduate, age 31, married. Nine years' practical experience with large concerns, including executive experience and the handling of men. Desires change of location. I-306.

ASSISTANT TO EXECUTIVE OR EXPERIMENTAL ENGINEER. Stevens M.E. graduate, age 28, married, finishing present engagement, returns East early in September. Three years' successful experience in executive and experimental work in natural gas, and two years' in power-plant operation. Possesses energy, initiative, self-confidence. Desires position with large industrial or engineering concern. Initial salary not a primary consideration, but position must be permanent and offer a future. I-307.

ASSISTANT SUPERINTENDENT OR CHIEF DRAFTSMAN, age 28, experienced on tools, jigs and fixtures for motors or munitions, wishes to engage permanently with an established firm in this business. Ability has been proved. Salary \$2500. Location in the East preferred but not essential. I-308.

MANUFACTURING EXECUTIVE. M. E. Lehigh, age 30, wants to connect with a live organization producing mechanical material. Eight years' executive and practical experience in engineering and efficiency methods, tools, machinery, equipment and labor-saving methods. Specialty, quantity production of interchangeable parts. I-309.

MECHANICAL AND ELECTRICAL ENGINEER. Technical graduate, age 28, two years with engineering department of manufacturer of gas producers, internal-combustion engines and steam pumps; two years with manufacturer of electrical machinery. At present assistant gas and electric inspector in a large city. Also familiar with storage batteries and power-plant practice. I-310.

RECENT M. I. T. GRADUATE desires position involving efficiency, planning or time-study work. I-311.

SUPERINTENDENT OR WORKS MANAGER at present employed in that capacity wishes to make a change. Fifteen years' experience in the manufacture of medium-weight interchangeable cars in large quantities. Under favorable conditions would consider making an investment as a guarantee of good faith. I-312.

MECHANICAL ENGINEER AND PRODUCTION EXECUTIVE. Age 39. Practical experience as toolmaker, designer, foreman, supervisor of engineering, tool and experimental departments. Experienced in the manufacture of small and medium interchangeable parts, and knows how to handle men to get coöperation. At present employed but seeks larger field. Location preferred, New York City or vicinity. I-313

EXECUTIVE ENGINEER. M. E. Lehigh, age 43, with good experience along lines involving design, operation, construction, purchasing, management, etc. Several years in responsible charge of the construction of power and industrial plants. Wishes a position of responsibility connected with the commercial rather than the strictly technical side of engineering, as manager, assistant manager, superintendent, sales engineer, manufacturer's agent, etc. At present employed. Salary \$3000-3600. I-314

WORKS MANAGER or General Superintendent, age 36, desires connection with large plant making any product from automobiles to clocks. Broad-gage, fully trained executive, experienced in plant layouts, best shop practices, management-control methods, systems and man training. Successful in all jobs successively through production, design and control divisions. A man with vision equal to the possibilities of a business and accustomed to make plans become facts. Full details on request. I-315

MECHANICAL AND EFFICIENCY ENGINEER desires responsible position, any location. Technical education, M. E. and C. E., and 12 years' general engineering experience, including power-plant construction and operation, appraisal work, railroad and highway construction, general machine-shop work, installation, design and construction of heaters and general power-plant efficiency work. Good executive and well known as writer of technical subjects. I-316

CHIEF DRAFTSMAN with broad experience and a successful record desires position with a growing concern where his initiative and industry will lead to advancement. I-317.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and a Selected List of Engineering Articles

Industrial Research in the United States

THE Secretary of the Department of Scientific and Industrial Research (England), issued the first of a series of papers projected by the Advisory Council, and bearing on industrial research. It contains a fully illustrated report of Mr. A. P. M. Fleming on Industrial Research in the United States of America, based on a visit to America last year. The report is divided into sixteen sections, is preceded by a short introduction, and has a good index. The author deals with every kind of industrial research as undertaken by (1) manufacturing corporations; (2) associations of manufacturers; (3) universities and colleges; (4) national institutions; (5) commercial laboratories; and (6) scientific societies. He next discusses the questions as regards (1) endowments for scientific research; (2) the coördination of research in the United States; (3) the selection and training of research men; (4) the fundamental consideration in industrial research; and (5) the organization of British industrial research. All these are fundamental questions which the author's experiences have raised in his own mind or which his readers will be likely to ask. To some of them he suggests answers which cannot fail to stimulate thought and discussion. Industry is the basis of national prosperity, and no stone should be left unturned to facilitate its progress. The instances adduced by the author show that in this respect research is of the utmost importance. The nation is entering upon a new phase in industrial and economic life, and its development will be governed largely by the extent to which new scientific knowledge is obtained and is turned to the benefit of all concerned. (*The Foundry Trade Journal* vol. 19, no. 187, July 1917, p. 358)

Research as a Profession

Address delivered by Dr. P. G. Nutting before the joint meeting of the Worcester Polytechnic Institute and Engineering Societies on May 18, 1917. The author is engineer in charge of the Research Department of the Westinghouse Electrical and Manufacturing Company at Pittsburgh, Pa.

The most interesting part of the address is that referring to industrial-research organization.

It is the opinion of the speaker that industrial research is preëminently fitted to be carried on by teamwork. He believes that this system is much more efficient than the elimination cell system, where each leading man has a room, or suite of rooms, to himself and keeps his work to himself. In the ideal organization two or three men work together on the same large problem, or group of problems, the aim being to have a good theoretical man and a good experimentalist working together as much as possible, or even a physicist and a chemist in some cases.

The characteristic of the teamwork plan is the conference system. The five or six men most interested in the problem meet for an hour each week to discuss it in its various aspects, to plan new work and to consider various applications of the results obtained. The ideal conference is composed of not less than four, or not more than eight men, and includes an efficient stenographer. To one experienced in such teamwork the results of getting together are simply amazing. A good suggestion is no sooner made than capped by a better one, and the saving in time and effort is almost incalculable.

The conference system aids in putting useful results before the other wing of the Research Division, and before the Patent Department. In the Westinghouse Company, at each of the conferences, were present representatives of the other wing of the Research Division charged with taking up any results immediately applicable; there is also present a member of the Legal Department, who takes care of any ideas worth obtaining. This plan of conference relieves the scientific men from responsibility for calling the attention of the works, or of the Patent Department, to useful obtainable results. (*Journal of the Worcester Polytechnic Institute*, vol. 20, no. 5, July 1917, pp. 312-322.)

French National Laboratories for Scientific Research

The French Academy of Sciences appointed in 1916 a special commission to study the question of the need of national laboratories in France. After reviewing what private initiative has done in France and what the government and private enterprise have accomplished in other countries, notably in Great Britain, the United States and Germany, the commission concludes that there is an urgent need in France for the establishment of a national laboratory for scientific research. Such an institution could be placed under the control of the French Academy of Sciences in the same way as the National Physical Laboratory in London is placed under that of the Royal Society.

After hearing the report, the Academy of Sciences has passed a resolution to the effect that the establishment of a National Laboratory for Physical Science and Mechanics is highly desirable, and that it should be specially entrusted with the work of scientific research for the purpose of promoting industry. The resolution contains some hints as to the status, organization and administration of such a laboratory, further details of which are elaborated in the commissioner's report. As regards financial support for the new institution, the report states that in France it would be useless to wait for the large industrial firms to combine and take the initiative, as they did in Great Britain, and to try to start the laboratory without a Government grant. To insure a successful start for the institution, about \$100,000 would be required, apportioned among the central institution and its branches. (*The Iron Age*, vol. 100, no. 6, August 9, 1917, p. 311)

The New Jersey Zinc Company's Franklin Laboratory

The Franklin Laboratory was designed mainly for the analysis of products from the two concentrate mills in its

[illegible] as determinations of zinc, iron, manganese, etc., in the ores. Within the last five years, however, it has been found advisable to examine most of the supplies of the mills, and therefore additional space and equipment was allotted for the examination of such substances as oils, greases, soaps, alloys, fuels, paints, explosives, and water.

As the greater part of the determinations carried on are volumetric, good light is a very important factor, and, with this in view the interior walls of the building were constructed of white enameled tiles laid in Keene cement. This also gives a clean and attractive appearance to the room. As the zinc titration requires a constant light, which is not available, especially in winter, two artificial-daylight lamps were installed and proved to be fully satisfactory.

In the old laboratory great difficulty was experienced in keeping the wooden floor in good condition. Therefore in the new building the wood was treated with aniline black; it is now in excellent condition despite the fact that in many places it has been occasionally subjected to the action of concentrated acids. (D. Jenkins, in *Bulletin of the American Institute of Mining Engineers*, August 1917, pp. 1181-1185, 5 figs.)

A New Tool Steel

British papers contain an announcement, on behalf of Darwin & Milner, of Sheffield, of the discovery of a tool steel stated to be equal in durability and hardness to high-speed steel, yet of which tungsten is not a component.

The new steel is called cobalt-crom, and is based on a discovery that by adding cobalt to chromium carbon steel the latter is converted into a steel which has red-cutting hardness.

Tungsten high-speed steel has not been used to any large extent for milling cutters, taps, reamers, etc., and Darwin & Milner estimate that at least 90 per cent of this latter type of tools are still being manufactured from carbon steel, which is probably mainly due to the difficulty which the toolmaker experiences in hardening such tools. Tungsten high-speed steel requires hardening at from 1250 to 1350 deg. cent., if the best results are desired. To try to obtain this heat for milling purposes is very risky, and to harden at a lower heat gives less satisfactory results.

It has been found, on the other hand, that the maximum heat necessary for the hardening of the new steel is only 1000 deg. cent. It is stated that hardening is satisfactory nearly always when the tool is allowed to cool naturally in air free from drafts and currents, and it is claimed to be possible with the new steel to get absolutely the same standard of hardness throughout.

It is also stated that the cutting efficiency of the new steel is quite equal, even in the form of castings, to that of tools made from forged or rolled bar, in which high-speed steel is supplied commercially, and, as the material in the molten state is much more liquid than high-speed steel, it lends itself to all forms of tool-casting.

As stated in *The Iron Age* (August 16, 1917, page 365), a convention of representatives of the iron and steel industry of Germany has been recently held at Düsseldorf at the instance of the Association of German Steel Makers. It was urged that it was necessary to extend the system of metallurgical research in order to be equipped in every respect for the inevitable economic contest after the war. It was decided to form an institute for undertaking iron and steel research in association with the Kaiser Wilhelm Company, and to raise the necessary funds almost entirely in the iron and steel trades.

Notes from the Engineering Colleges

Equipment of Laboratories—Investigations in Progress—Changes in Curricula

BELOW is a continuation of the review of professional work being undertaken at the engineering colleges. The articles contain information regarding (1) characteristics of laboratory equipment, (2) tests or researches under way or in prospect, (3) important changes in curricula.

The articles are concluded this month.

NORTHWESTERN UNIVERSITY, COLLEGE OF ENGINEERING

Equipment: Electrical Laboratory. The apparatus is provided with special features to make it effective for a general laboratory study in connection with a five-year curriculum leading to the degree of Bachelor of Science at the end of four years and to the degree of Electrical Engineer at the end of five years. Class and laboratory instruction are closely correlated in setting forth and making concrete the fundamental scientific principles underlying the theory, the operation and the design of the electrical apparatus which form the basis of electrical engineering.

Laboratory of Applied Mechanics. This laboratory work is taught directly in connection with the theoretical study of strength of materials. The present equipment includes a 20,000-lb. universal testing machine; a 50,000-in-lb. torsional machine; a 5000-lb. end-load bending machine; a 200,000-lb. compressive-testing machine; an Upton-Lewis toughness-testing machine; a Smith endurance-testing machine; a Fairbanks cement-testing machine, and other apparatus.

Shop Laboratory. The equipment is adapted to instruction in an understanding of shop processes as distinguished from the acquirement of manual skill. The machines are individually motor-driven.

Hydraulic Laboratory. The equipment includes tanks, a centrifugal pump, a Pelton wheel, a hydraulic ram, and other apparatus for the study of small quantities of water flowing through weirs, orifices, nozzles and pipes.

Engine Laboratory. The equipment includes a Corliss engine, a Ball engine equipped with both a throttling governor and an automatic cut-off governor, a Kerr turbo-generator set, a Foster superheater, a steam-flow meter, a Wheeler condenser, and a Foos gas engine equipped for use with various fuels and equipped with hit-and-miss governor and throttling governor, and all necessary instruments for power-plant testing.

Research: Primary and storage batteries; work upon residual stresses, with particular respect to the persistence of these stresses over a period of two or three years; work on web stresses in an I-beam (preliminary work on a 7-in. I-beam has given encouraging results; a 15-in. 42-lb. I-beam is practically ready for testing); efficiencies of gas engines, particularly with kerosene as fuel.

Curriculum: No change is contemplated. The purpose is to furnish a thorough training for the profession combined with the general training of the man. The fundamental aim of education is steadfastly kept in mind in both the class room and in the laboratory, namely, to communicate knowledge of principles which are of broad application and to discipline the intellect. It is believed that the objects of the class and laboratory work are identical, and to this end emphasis was laid on the selection of apparatus which would illustrate the *why*, the rationale of the phenomena under investigation and the *why* of practice.

The Ohio State University

Equipment: Usual apparatus for work in strength of materials, hydraulics, friction, lubrication, gas, power and steam engineering. This is one of the six universities chosen to establish a cadet aviation school, which started on May 21, to which 25 men will be sent by the War Department each week, given three weeks of intensive military drill and five weeks of instruction in aviation work, and then sent to the Wright flying field at Dayton for their training in flying.

Research Work: Tests on gas engines, on friction and lubrication, and the flow of fluids through pipes and diaphragms; feed-water regulators, and gas tractors.

University of Wisconsin

Research Work: Thesis research on the cycle of temperature in a gas engine. The method originally contemplated was as follows: A number of extremely delicate thermocouples connected in parallel were to constitute a source of current which was to be recorded by an oscillograph. The couples were to be calibrated by rapid introduction to and withdrawal from an electrically heated tube furnace the known temperature of which approximated that to be measured. After some preliminaries a string galvanometer was substituted for the oscillograph on account of greater sensitiveness. (Unfinished.)

Thesis study of the vibration of automobile motors, a mechanical amplifier being used to obtain record which was on a smoked drum alongside a chronographic time line. So far the mathematical deduction that the principal vibration of a four-cylinder motor was of double periodicity with respect to the rotative speed, has been confirmed.

Experimental Work: A 100-hp. uniflow engine has been under test during the past year, and some additional work has been accomplished in testing the laws of flow of oil of a viscous nature through small orifices, and on the behavior of concrete slabs under varying temperatures and moisture conditions.

Syracuse University

Equipment: The laboratories, mechanical, electrical and hydraulic, are fairly well equipped for research; there is a foundry, woodworking department, forge and machine shop. The chemistry department of the University is exceptionally well equipped for research work.

Research Work: The college has done a limited amount of research work; the mechanical department contemplate making a test on shafting friction next fall.

Tufts College Engineering School

Curriculum: A new curriculum was adopted this year for all departments. Its first object is to avoid the differentiation of courses during the first two years, and, in the case of such closely allied courses as mechanical and electrical engineering, or civil and structural engineering, to require a common course for three years. The fourth year will then be used for intensive and specialized work more closely allied to professional work. To enable a more discriminating selection of a specialty during the senior year, we have introduced the fundamental principles of each department in courses to be given during the freshman and sophomore year, and required of all students. The elements of surveying, hydraulics, mechanics, mechanism, heat engineering, electrical engineering and chemical engineering are given during this period. These are taught with a proper consideration for the coordination of theory and practice, and in some cases requiring the practice to precede the theory. Many of these subjects are taught by the heads of the respective departments.

A recent addition to the laboratories is in the Department of Electrical Engineering, which has completed the installation of apparatus for laboratory work in connection with its instruction in telephony. There are two complete central offices consisting of standard types of switchboards, terminal and power apparatus, etc., having a sufficient number of circuits equipped for any demonstration desired. One is a simple magneto office with a single-position switchboard. The other is a common-battery office with a three-position switchboard. The circuits are arranged to provide a toll, local and trunk position. Standard apparatus has been used throughout and recent practice followed in its arrangements so that the students may become familiar with the practical side of telephony as they study its principles.

Agricultural and Mechanical College of Texas

Equipment: Texas is essentially an agricultural state and is undeveloped in engineering. For this reason the chief lines of investigation, research and preparedness are along agricultural lines. The present equipment is ample for materials, dynamic, hydraulic, pneumatic, metallurgical, automotive, electrical, chemical, and other engineering instruction, research and study. A mechanical-engineering building is in course of construction and will enable the college to handle almost any kind of research in mechanical lines.

Curriculum: A few years ago changes were made which put the courses up to the standard courses of the country. Recently, modifications in the curricula were inaugurated to meet the needs of the country in military preparedness. A strong feature of the college is its military work. A Reserve Officers' Training Corps has been established and at the time of writing more than a hundred seniors and undergraduates have gone to the Reserve Officers' Training Camp. A number of seniors have also been sent to the different branches of the Naval service.

Purdue University

Faculty: An executive committee of fifteen members has been constituted which takes care of routine business and reports to the general faculty. The latter body retains the legislative power and controls all questions involving new rules. The executive committee meets twice a month and the general faculty once a month on stated days.

Engineering Experiment Station: This has been created for the conduct of research work in engineering. The dean of the engineering schools will be director of the station and will have associated with him the heads of the engineering schools in a board of management. The station will be in a position to extend the same assistance to the manufacturing industries and public utilities of the State as has been afforded the farmers by the agricultural station.

Short special courses will be started to prepare men for special Government service.

Research Work: Effect of flat spots on railroad car wheels; testing of side frames and low temperature effects on steel rails; testing once a month for the past twelve months, of a locomotive to determine the loss of efficiency due to boiler scale; study of the fire-carrying possibilities of locomotive

sparks at known temperature, testing of brake beams; work on carburetors, work on a bituminous gas producer; research on different kinds of pulleys and belt of different tannings; tests of two types of refrigerating cars; establishing a correct method of measuring heat and a proper rate of charge to the consumer using hot water or steam from a central heating station, comparative tests of all the bituminous furnace coals of Indiana with coals from Pennsylvania and Illinois; the possibilities of powdered fuel in stationary boilers.

The University specializes in Railroad Engineering and Gas Engineering.

RENSSELAER POLYTECHNIC INSTITUTE

Equipment: The laboratory is primarily fitted for instruction work. There has been no specialization.

Research: During the past year work on the determination of the coefficient of heat transfer through blocks of commercial insulation has been carried out.

Curriculum: A course in military engineering and instruction will be established next year.

MICHIGAN AGRICULTURAL COLLEGE

Equipment: The laboratories are provided with typical steam engines, gas engines, pumps, electric motors, air compressors and heating apparatus, the ordinary apparatus required for determining the strength of materials, etc.

Research Work: Carburetor behavior, tests on various kinds and makes of gasoline engines, problems involving repetition of stress in materials, and combined stresses in materials, such as combined torsion and bending, experiments on the power required to operate drills at various speeds and feeds.

Curriculum: A course in chemical engineering has been added.

WASHINGTON UNIVERSITY (ST. LOUIS)

Equipment: Laboratories are equipped to do research work on fuels, gas and steam appliances, automobiles, etc., and especially equipped for testing cutting tools.

Research Work: Tests have been made on steam-turbine nozzles, automobiles, and high-speed steel cutting tools, but the work may not be completed owing to the seniors carrying on the work being excused for military duty.

High-Speed Steel Alloys

A patent issued to Radclyffe Furness, of Jenkintown, Pa. (assignor to the Midvale Steel Company), states that if a certain amount of both cobalt and tungsten be added to an ordinary high-speed tool steel, containing tungsten, chromium and vanadium, a substantial increase in cutting efficiency is attained. The amount of uranium is so small that it cannot be said to replace the known high-speed tool-steel additions, its presence even in apparently negligible proportions improving the efficiency of the tools.

	Preferred analysis, per cent	Limiting proportions, per cent
Cobalt	4.5	3.0 to 7.0
Uranium	0.7	0.1 to 2.0
Tungsten	13.5	12.0 to 20.0
Chromium	3.5	2.0 to 6.0
Vanadium	1.5	0.5 to 2.0
Carbon	0.7	0.5 to 0.9

(1,233,862. July 17, 1917.) (*Metallurgical and Chemical Engineering*, vol. 17, no. 4, August 15, 1917, p. 191)

This Month's Abstracts

The latent heat of steam is a subject still attracting the attention of engineers.

In the present issue will be found an abstract of an investigation by Frank B. Aspinall, of interest because it establishes certain novel facts. Among other things the claim is presented that water can be present in steam in some form which is not a mechanical mixture, and further, that steam has a dewpoint like air.

The basic laws for heat of steam are enumerated, and values are offered for the latent heat of steam and heat latent, when absolutely no water is present, as well as for the constant representing pressure multiplied by the volume.

In the section Aeronautics is abstracted an article on measuring stresses in aeroplane wires by means of an instrument called a frequentiometer, which utilizes the phenomena of resonance for this purpose.

In the same section is presented a description of a German aeroplane possessing several features of interest, in particular the location of the radiators on the sides of the fuselage instead of in front.

In a paper before the American Society of Heating and Ventilating Engineers, Arthur K. Ohmes shows by a parallel series of determinations that the value of air flow cannot yet, except in the simplest cases, be determined by the application of the known formulæ and coefficients of resistance.

The influence of high temperature upon the elastic and tensile properties of wrought iron is discussed in detail by Frank A. Epp and E. Olney Jones. They come to the conclusion that for iron intended to be used at high temperatures a different factor of safety should be used than for iron used at low temperatures.

In a report abstracted from *Stahl und Eisen* through a British periodical, are given the results of experiments carried out in Germany with the view of ascertaining the influence of carbon, silicon and phosphorus on the mechanical strength of cast iron.

The practice of a central station of the Toledo Railways and Light Company in the use of combination coal and gas firing, reported in the section Firing and Fuel, indicates that the amount of coal burned per hour with the combination firing is practically the same as the amount burned when coal alone is fired. The efficiency of the boiler, furnace and grate was not materially improved by the use of combined firing, and the cost of evaporating water with the combined firing is 8 per cent higher than with coal alone; but on the other hand, an added evaporative capacity of 31 per cent was obtained with 50 per cent less investment than would be required with coal alone.

The quenching process, and in particular the influence of the surface factor, is discussed by Lawford H. Fry, member of the Am.Soc.M.E., in the abstract in the section Machine Shop. The writer, among other things, makes a careful distinction between the rate of loss of heat by the body subjected to quenching and its rate of loss of temperature, and shows that under certain conditions water-cooled pieces of steel may have the same properties as air-cooled pieces.

The brick-arch tests of the Pennsylvania Railroad, reported in the section Railway Engineering, present a good example of carefully conducted experiments on an interesting and difficult subject. These experiments appear to have established the fact that both the equivalent evaporation and the efficiency of the boiler are noticeably improved by the presence of the arch.

REVIEW OF ENGINEERING PERIODICALS

Aeronautics

NEW METHOD FOR REGULATING THE TENSION OF AEROPLANE WIRES BY MEANS OF A FREQUENTIOMETER.

Carlo Maurilio Lerici

In regulating the tension of aeroplane wires it is necessary that the distances between the ends of each wire should be constant, that symmetry of construction should be maintained and that the tension itself should not exceed a certain limit determined either practically or by calculation.

Since, however, in the vast majority of cases, this regulation is carried out in a purely empirical manner, it is not unusual that a difference of 30 to 40 per cent between the tensions of symmetrical wires in the same machine occurs, and quite often such differences do not produce any noticeable alteration in the symmetry of the aeroplane while it is at rest.

The process described in the present article is said to have been successfully tested out. It appears to be simple and susceptible of great precision. This method of measuring the tension of wires utilizes the phenomena of vibratory resonance and is analogous to that employed by Captain Largier in his musical tension meter.

The present apparatus is based on the application of the formula

$$T = \frac{4\,l^2 p n^2}{g} = K n_1^2$$

where T is the tension of the wire: l the length of the wire: p the weight of the wire per unit of length, n_1 the frequency of vibration and g the acceleration due to gravity, all in metric units. For a given wire, in order to determine the value of T, all that is necessary is to know that of n.

The present apparatus is so designed that n_1 can be measured directly. It is nothing else but a frequentiometer similar to that used for measuring the frequency of alternating currents, but more simple in construction and more convenient to handle.

As shown in Fig. 1, the apparatus consists of a series of steel plates of different lengths rigidly held at one of their extremities. In accordance with the usual formula the dimensions of each plate are in a relation with the natural period of oscillation of the plate expressed by the formula

$$t = \frac{1}{n} = \frac{8L^2}{\pi b (1.198)^2}\sqrt{\frac{5d}{6gE}}$$

where L is the length of the plate: b the radius of inertia of its section: g acceleration due to gravity: d density and E modulus of elasticity of the plate.

In accordance with the laws of resonance, when a plate rigidly held at one end is placed into light contact with a vibrating string, it obtains a very noticeable maximum oscillatory movement, provided its natural period of oscillation is

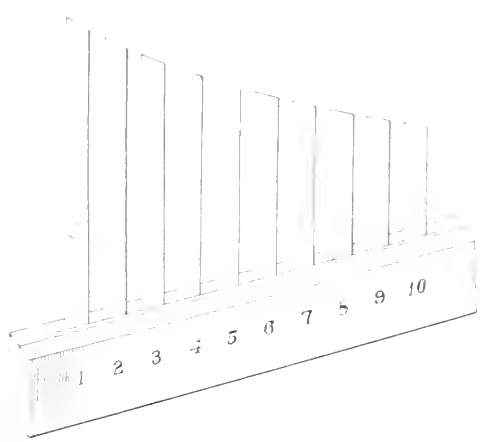

FIG. 1 FREQUENTIOMETER FOR DETERMINING THE TENSION IN AEROPLANE WIRES

equal to that prevailing at the instant in the wire. It is not even necessary that the plate be in direct contact with the vibrating wire, and it is enough that the support of a series of plates of a frequentiometer be placed in contact with one end of the vibrating wire. In this way there is no difficulty in determining the particular plate of which the natural period of oscillation is nearest to that of the vibrating wire. The proper selection of a set of plates makes it possible to secure indications of a far higher precision than can be obtained by the empirical methods employed in the majority of shops.

With the type of frequentiometer described there is a possibility that both the fundamental vibration and the secondary vibration may appear, if in the set of plates used there are two plates such that the period of one is twice as great as the period of the other. In practice, however, the series of plates employed reproduces only a limited number of vibrations. Furthermore, even should a case of multiple resonance be observed, all that would be necessary would be to consider only the indications of the plate having the least period.

In fact, for regulating the tensions of wires in the fuselage

[illegible] of modern medium powered machines (100 to 400 hp.), it is enough to have a set of plates of from 20 to 40 oscillations, and actually a dozen plates will give indications sufficiently precise for all practical purposes. With [illegible] the average error due to the presence of turnbuckles does not exceed five per cent.

The frequentiometer may be so designed as to have a scale in kilograms for each type of wire. If each plate has a mark showing its frequency, a corresponding tension in the wire may be found from a chart giving the interrelations of the frequency, the length of the wire, diameter (or weight per meter) and the tension. Two such charts are given in the original article. (Nouvelle méthode pour le réglage de la tension des haubans des aéroplanes au moyen d'un fréquencomètre, Carlo Maurilio Lerici, *Le Génie Civil*, vol. 71, no. 3, July 21, 1917, pp. 39-41, 5 figs., *d*)

The Albatros D.I "Chaser" Biplane

Description of the German Albatros "Bu" chaser scout machine.

Although being comparatively heavy and lacking the high speed and other performance qualities possessed by some of the machines of the Allies, it has proved a formidable fighter. The present description is based on a thorough examination of a machine brought down some six months ago on the British front.

The fuselage is of the monocoque type, built up entirely of wood without any wire bracing.

The arrangement of the planes, contrary to the usual German practice, has neither sweep-back nor dihedral, the top plane, in fact, being one complete unit. A somewhat novel feature consists of the method of adjusting the stagger of the top plane from 0 to 12 cm. by moving it along the top of the cabane. This is done in the following manner. In each end of the top horizontal tube of the cabane is formed a slot which receives an eyebolt passing through the main spar of the plane. Each slot has five holes passing horizontally through the tube, one of which, according to the adjustment required, receives the bolt that locks the eyebolt in the cabane. Only one pair of struts on each side of the fuselage separate top and bottom planes, these struts being of streamline steel tubing. The top fittings are slightly different from the lower ones, which are adjustable. The main spars are located well forward, the front ones being some four inches from the leading edge and spaced to fit $7\frac{1}{2}$ in. from the rear one. They are of rectangular section, fabric-bound, and are beveled off from the top at the extremities. The lower plane is attached to an abutment built out from and flushed with the side of the fuselage. The stabilizing plane, semi-elliptical in plan form, is divided into two parts and is exceptionally thick ($5\frac{3}{4}$ in.). It is non-lifting and is mounted in the line of flight without any external bracing. Hinged to the trailing edge of the stabilizing plane is a single elevator balanced by small triangular extensions forward of the outer extremities. The system of supporting the rudder and tailskid is described in detail.

The fuselage is a compromise between the formal standard Albatros system and the true monocoque type. In section it varies from circular at the nose to a horizontal knife edge at the rear and is flat-sided with rounded top and bottom in the center. The method of construction of the fuselage is described in some detail.

The radiators differ from those usually employed. They are of the honeycombed type and are mounted one on each side of the fuselage. Above and at the left of the camshaft is a flat water tank, one end connected to the engine jacket and the other end to the tops of the radiators. The lower orifices of the radiators are connected to the water pump at the rear of the engine. On each side of the engine is mounted a machine gun synchronized for firing through the propeller. (*Flight*, vol. 9, no. 26/444, June 28, 1917, pp. 628-641, illustrated, *d*)

Air Engineering

A Study in Air Measurements and Air Flow, Arthur K. Ohmes, Mem.Am.Soc.M.E.

Data of an interesting investigation bearing on the comparison of test results on one hand, and theoretical results of air movement on the other hand, with special reference to flow of air through small channels under very slight pressure differences.

Among other things, these tests have established that there are now fairly complete means available for engineers in conducting tests on air-flow measurements.

The writer checked the results of tests with such tests as would be theoretically derived by the application of proper formulæ, and found the following situation to exist: As regards the pressure differences necessary to drive a certain amount of air through a channel at an assumed velocity of 10 ft. per sec., he found for the square channel that, whereas the pressure was 0.092 in. of water, the test showed only 0.032 in., or a proportion of 1 to 2.88.

Likewise, in the case of the round channel, the proportion between the test magnitude and the theoretical value was as 1 to 2.5. In other words, the theoretical resistances are greater than the accurate testing results indicate them to be. On the other hand, nearly all coefficients are usually increased by the authors some 15 to 20 per cent for safety reasons.

As regards coefficients of resistance, the data do not appear to be entirely conclusive, but as regards the velocity of air secured under certain pressure differences, it was found that, whereas, according to theory, for a given pressure difference a velocity of 5.95 ft. per sec. would have been obtained with the square channel, and 6.2 ft. per sec. with the round channel, the actual velocities were in each case 10 ft. per sec., or 1.68 and 1.61 times as much as the theoretical values. (These latter neglect the very small frictional losses.)

Altogether, it would seem that tests of this kind cannot as yet be dispensed with, because we have scarcely sufficient coefficients of resistance at our disposal to determine flow of air in any but the most ordinary duct systems, and even this with no scientific accuracy. (*Journal of the American Society of Heating and Ventilating Engineers*, vol. 23, no. 4, July 1917, pp. 577-586, 9 figs., *et*)

Engineering Materials

The Briquetting of Metal Swarf

Third article of a series. The preceding two articles (*Engineering*, June 8 and 15) describe the advantages derived from the application of briquetting to scrap which has to be remelted in ordinary furnaces.

Taking British costs as a basis, it appears that the cost of briquetting in a plant which is kept constantly at work may not amount to more than, say, 25 shillings (say, \$6.00) per ton, including allowances for standing charges, such as overhead, depreciation, etc.

As regards machinery, the writer states that there is already

under construction by a British manufacturer a machine which is to have an output of some $6\frac{1}{2}$ tons per hour when dealing with non-ferrous scrap. The question of the size of the machine has an effect on the cost of briquetting per ton, the larger the machine, other things being equal, the less the cost per ton, provided enough material for the machine is available.

The briquets made by the larger non-ferrous machines are ordinarily in the form of a cylinder 6 in. long by 6 in. in diameter. According to a statement made to the writer by a representative of the Southwark Engineering Company, of Philadelphia, Pa., the approximate weight of briquets 6 in. long by 6 in. in diameter is as follows:

From steel turnings, 38-43 lb.
From iron turnings, 35-40 lb.
From copper turnings, 43-49 lb.
From brass turnings, 41-46 lb.
From aluminum turnings, 13-15 lb.

As regards the method of briquetting, a British engineer, who designed the plant mentioned in the earlier part of this abstract, has found, in the first place, that it is much better to use oil as the hydraulic fluid than water. He found that with oil, in addition to avoiding corrosion, the leathers last much longer and the cost of repairs and renewals is considerably decreased. Further, he has found that there is a distinct tendency for the molds to become barrel-shaped, so that if they form an integral part of the mold table, the expense of putting them right is very high. He has, accordingly, made the molds entirely separate from the table, and when they become worn he simply removes them and replaces them by others, this being done at much less cost and much more quickly than repairing molds on the table.

As regards binders, he has found that the employment of a suitable binding material is a most important factor in the production of successful briquets. He himself uses a mixture of linseed oil and resin melted together and mixed with the scrap. The proportions here recommended are about $22\frac{1}{2}$ lb. of oil and $1\frac{1}{2}$ lb. of resin to the ton of scrap. The briquets were made with this binding material and dried for 12 hours in an oven. He also lays great emphasis on the necessity for employing heavy pressures. For the non-ferrous briquets which he is making he puts on a maximum pressure of 180 tons dead load, which means an actual pressure on the scrap of about $21\frac{1}{2}$ tons per sq. in. (*The Engineer*, vol. 123, no. 3208, June 22, 1917, pp. 557-558, 2 figs., *d*)

The Influence of High Temperature Upon the Elastic and Tensile Properties of Wrought Iron.

Frank A. Epp and E. Olney Jones

The modern use of iron and steel under stress at temperatures considerably above the usual range makes an investigation in this field of possible commercial and engineering value.

For metals at ordinary temperatures, the use of a proper factor of safety brings the stress for which the piece is designed well within the elastic limit. But, as the results of this test would indicate, at higher temperatures this design factor of safety will have to be modified greatly or the work will have to be designed wholly on the basis of the elastic limit.

As examples of the employment of iron in stressed condition at high temperatures, the writer quotes the following: Temperatures of superheated steam vary now from 450 to 550 deg. fahr., and the strength of tubes, valve stems, etc., as affected by these temperatures, is, indeed, worthy of serious consideration. Other examples of the same condition are encountered in boiler construction, metal rigging above large crucibles or ladles carrying molten metal, etc.

In the present series of tests wrought iron was brought to the desired temperature in an electric furnace (and was, therefore, not affected by the gases of combustion), and then submitted to various physical tests.

The article describes in detail the apparatus used, methods of calibration and conduct of tests. As regards the apparatus, the most interesting piece used was the extensometer rigged up for this purpose. While very simple in construction, it has a least count equal to 0.0002.

A complete summary of all tests is given in the accompanying curves.

From these results it appears that the ultimate tensile strength of wrought-iron bars increases as the temperature increases from 70 deg. fahr., until a maximum is reached between 350 deg. and 550 deg. fahr.

From the temperature of maximum strength the tenacity diminishes rapidly until the highest temperatures covered by these tests are reached.

The greatest gain over the strength of the metal at 70 deg. fahr. was 37.6 per cent. This occurred at 430 deg. fahr., as judged from Fig. 2. The loss at 1000 deg. fahr. over the strength of the metal at 70 deg. fahr. was 53.5 per cent. A continuation of the curve at 1200 deg. fahr. indicates a loss in strength of 75 per cent.

The elastic limit appears to decrease from 70 deg. fahr. to about 270 deg. fahr., showing a maximum decrease of about 13 per cent. From that temperature the elastic limit appears to increase suddenly to about 350 deg. fahr., where it reaches its maximum value of about 10 per cent above the stress at 70 deg. fahr. From here on it gradually drops, and at 1000 deg. fahr. shows a loss of 70 per cent over the elastic limit at 70 deg. fahr.

Owing to a period of rapid yielding without increase of stress, the yield point is well defined at moderate temperatures. This yield point, however, vanishes at about 500 deg. fahr., and the stress-deformation curve assumes a gradual slope from the start to finish.

With reference to elongation under stress, this peculiarity is noticed: that greater rigidity exists under certain stresses

The physical properties of wrought iron are materially affected by high temperature.

The ultimate tensile strength increases as the temperature increases from 70 deg. fahr. until a maximum is reached between 350 deg. and 550 deg. fahr.

Tenacity diminishes rapidly with increase of temperature.

The elastic limit appears to decrease from 70 deg. fahr. to about 270 deg. fahr., showing a maximum decrease of about 13 per cent. From that temperature the elastic limit appears to suddenly increase to about 350 deg. and then gradually drops.

The curve of elongation versus temperature is irregular.

For iron intended to be used at high temperatures a different factor of safety should be adopted than the one for iron used at low temperatures.

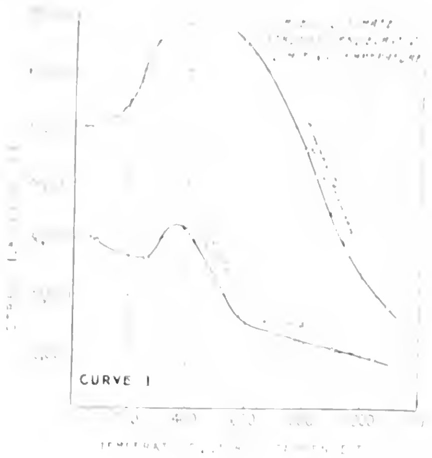

FIG. 2 CURVES OF ULTIMATE STRENGTH AND ELASTIC LIMIT VERSUS TEMPERATURE FOR WROUGHT IRON

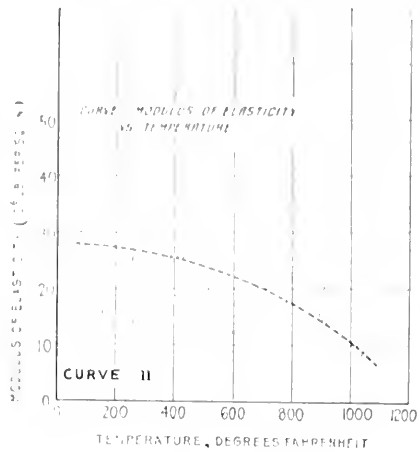

FIG. 3 CURVE OF MODULUS OF ELASTICITY VERSUS TEMPERATURE FOR WROUGHT IRON

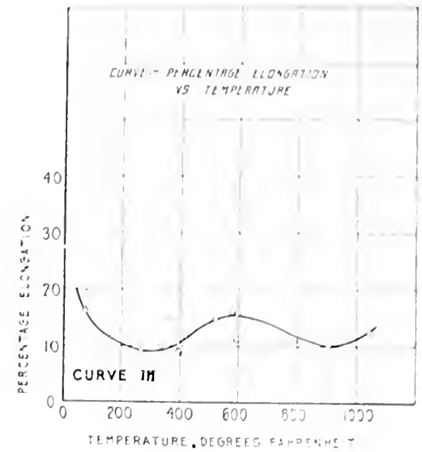

FIG. 4 CURVE OF PERCENTAGE ELONGATION VERSUS TEMPERATURE FOR WROUGHT IRON

at intermediate temperatures than at either higher or lower temperatures. Thus it will be noticed in Curve III that at 300 deg. fahr. and 900 deg. fahr. the metal shows only about half the elongation that it shows at 70 deg. fahr. It is surmised that beyond 1000 deg. fahr. the curve gradually rises and the metal exhibits powers of greater ductility as it approaches a workable heat.

Other remarkable features in the elongations are found in bars tested at temperatures varying from 200 deg. to 400 deg. fahr., in which there are displayed alternate periods of rigidity and relaxation under increasing stresses.

It will be readily observed how irregular Curve II is beyond the yield point. Some of the tests taken at this temperature showed even greater irregularity. The repetition of these intervals of rigidity and relaxation is suggestive of some remarkable change taking place within the metal in this zone of temperature, conspicuous in a series of tests possessing many remarkable features.

The contraction of area at the place of rupture varies with the temperature of the bar. It appears that the contraction of area of wrought-iron bars is a great deal less between 200 deg. and 600 deg. fahr. than at 70 deg. fahr., and within this range of temperature there is a tendency to fracture obliquely across the bar.

The results obtained for the modulus of elasticity have very little value, except that they indicate a gradual decrease.

It is shown conclusively that should similar iron be used in work where the design factor of safety was five, and where the temperatures were 900 deg. fahr. or above, the part under consideration would be stressed beyond its elastic limit if the allowable stress was applied. Furthermore, at that temperature the factor of safety on the ultimate strength would be reduced to three. Curve I shows the relation of ultimate strength and elastic limit throughout the complete temperature range.

For tubes, valves, pipe lines, etc., carrying superheated steam, Curve I shows that at 600 deg. fahr. the elastic limit has fallen 50 per cent of its value at ordinary temperature. Hence a design factor of safety in superheater construction should be so modified as to give an ample factor on the elastic limit at this temperature. Assuming that the factor of safety is five on the ultimate strength at 70 deg. fahr., this would be equivalent to a factor of three on the elastic limit at the same temperature. Therefore, considering that the metal should never be stressed to more than one-third of its elastic power, at 600 deg. fahr. the factor of safety would have to be ten on the ultimate strength of the metal at 70 deg. fahr.

Reference to Curve III indicates that the metal is very brittle between 150 deg. fahr. and about 1100 deg. fahr. Where this state exists, it is, of course, impractical to work the metal. In other words, it would be better to work the metal cold than at 200 deg. fahr., at which temperature it might fracture without warning. Nine hundred degrees fahrenheit is even a more critical point, for here the ultimate strength and the elastic limit have dropped to less than half their original values.

The conclusions attained are rather startling. The wide fluctuations in the physical properties are not generally realized.

A brief bibliography of the subject is appended. (*Metallurgical and Chemical Engineering*, vol. 17, no. 2, July 15, 1917, pp. 67-71, 6 figs., *eA*)

THE METALLURGY OF FERROCHROMIUM. Robert J. Anderson

An article of a general nature describing the manufacture of ferrochromium and chromium steel and outlining the use of the latter.

Chromium in steel does not act as a scavenger, nor does it confer soundness on the steel as do silicon and aluminum. But added in small amounts it increases the tensile strength of the steel to some extent without markedly decreasing its ductility. When added in excessive amounts it causes brittleness.

The effect of chromium when added to steel is to raise the normal critical range, thus causing changes to take place at high temperatures and also more slowly. Hence, chromium steels are harder than ordinary steels, because quenching more effectively prevents the transformation of the austenite. When added to iron, chromium does not materially harden the metal. Chromium steels contain from 1 to 4 per cent or more of chromium, and the carbon may range from 0.50 to 2 per cent. (*The Iron Trade Review*, vol. 61, no. 2, July 12, 1917, pp. 75-78, 3 figs., *g*)

PROPERTIES AND STRUCTURE OF NICKEL STEEL. S. W. Parker

Data of experiments made at the testing department of the Bethlehem Steel Company at Steelton, Pa., in order to

determine the best annealing temperatures for two grades of 3.50 per cent nickel steel, commonly used for forgings.

The test bars used were forged down to 1 in. sq. by 6 in. long from two 4 x 4-in. billets of different grades. The writer describes in detail the methods of testing and states that the minimum hardness and tensile strength were obtained by annealing at between 1250 and 1350 deg. fahr., at which temperatures the structure had only started to break up and refine. The property most affected by annealing is the elastic limit. This was increased from 41,000 lb. per sq. in. in the unannealed bar to 50,000 per sq. in. in the bar annealed to 1400 deg. fahr., in which the grain was the finest in the series. This increase in elastic limit by refinement of grain plays an important part in annealing forgings, especially when the specifications require high elastic limits together with good ductility.

The best combination of physical properties in the case of 3.50 per cent nickel steel of 0.22 per cent carbon is obtained by annealing at a temperature ranging between 1400 and 1450 deg. fahr.

A similar series of tests on nickel steel of 0.41 per cent carbon indicated a general similarity in the properties. For this steel the best combination of physical properties is obtained by annealing at between 1350 and 1450 deg. fahr., the minimum temperature being lower than in the case of 0.22 per cent carbon steel. (*The Iron Age*, vol. 100, no. 2, July 12, 1917, pp. 67-69, 18 figs., *e*)

Metallurgy of Cast Iron

Mr. A. Stadeler, in recent issues of *Stahl und Eisen*, reports the results of experiments carried out by F. Wust and his pupils with a view of ascertaining the influence of carbon, silicon and phosphorus on the mechanical strength of cast iron. Various mixtures were prepared of Swedish charcoal pig with Swedish horseshoe iron, the silicon, manganese and phosphorus contents being varied by the addition of ferroalloys. As square or rectangular test bars are liable to develop a white iron at the edges, test bars cast round and turned down were used in the experiments. The quantity and character of the graphite appear principally to determine the mechanical properties, but these are materially influenced also by the pouring and method of cooling. With gray iron containing 1.5 per cent of silicon, small quantities of manganese, up to 0.3 per cent, increase the formation of graphite, but a further increase to 2.5 per cent has no influence. Cast irons high in phosphorus, contrary to existing ideas, may be improved by the presence of 1 per cent of manganese, or more, provided the rest of the ingredients has been fixed properly. With a rise in the proportion of graphite the strength of the iron in tension and bending falls off, as a rule. This is also the case with an increase in the percentage of carbon and silicon, both of which favor the formation of coarse graphite. With increase of phosphorus up to 0.3 per cent, and of manganese up to about 1 per cent, the strength in tension and bending increases. Phosphorus up to 0.3 per cent and also high graphite content enhance the bending strength, while manganese and silicon have the opposite effect. The resistance to specific impact shows the greatest sensitiveness to silicon, manganese and phosphorus. It diminishes rapidly as the phosphorus content rises until this reaches 0.6 per cent, above which the decrease is considerable. This property brings out the superiority of irons low in phosphorus, in respect of resistance to impact, which the tensile and bending tests fail to reveal. Hardness decreases with a rise in graphite content and is increased by a rise in manganese and phosphorus. It does not seem to be affected by the silicon content, but the physical properties of cast iron depend not only on the percentage but also on the character of its graphite content, and an explanation of the difference in the physical properties of test pieces containing the same percentages of carbon can be readily found by an examination of their microstructure. (*Page's Engineering Weekly*, vol. 31, no. 670, July 13, 1917, p. 19, *g*)

Firing and Fuel

Combination Coal and Gas Firing, Alex W. Morgan

Description of the Water Street Station of the Toledo Railways and Light Company, where conditions were such as to make it advisable to use this system of operation.

A large number of boilers of the company are now equipped for combined firing. At first gas alone was burned under six type S 475-hp. Stirling boilers equipped with McKinzie grates. These grates were partly covered with asbestos and a space of 12 in. wide was left uncovered for a secondary air port. The front of this air port was 40 in. from the burner tips and flush with the nose block of the ignition arch. Over this entire grate surface was spread firebrick crushed to the size of an egg, a layer varying in thickness from about $2\frac{1}{2}$ in., at the burner tips to 7 in. at the bridge wall. This cover deflected the flame and prevented it from striking the tubes directly. With this arrangement it was found that the rating was limited and the installation lacked flexibility.

To burn the gas directly above the coal in combination with it, a special tile with a 2.5-in. hole was developed and set so that the gas, when introduced into the firebox, was directed down against the coal. This tile was placed in the ignition arch next to the grate. All primary air was shut off and the gas in the firebox made to depend upon the secondary air coming through the fuel bed for its combustion.

Tests were then made to determine accurately the performances of the boilers thus equipped. The boiler used for these tests is of the Stirling type with a heating surface of 6680 sq. ft. and a superheating surface of 256 sq. ft., designed to deliver steam at 200 lb. per sq. in. pressure and 100 deg. fahr. superheat at rating.

The results obtained indicate that the amount of coal burned per hour with the combination firing was practically the same as the amount burned when coal was fired, and hence the additional rating developed was the result of the introduction of gas in the furnace. This additional rating was 31 per cent over that obtained with coal alone.

The temperature of the flue gases leaving the boiler was 43.4 deg. fahr. higher with the combination than with coal alone. The stack temperature during the tests was considered to be too high, and it was found that better results came from getting a lower stack temperature with the combination than from coal alone.

The efficiency of the boiler, furnace and grate was not materially improved by the use of the combination.

One of the conclusions arrived at is that the cost of evaporating 1000 lb. of water from and at 200 deg. fahr. is 8 per cent higher for the combination fuel than for coal alone, and 21 per cent higher for gas alone than for coal alone (taking the cost of fuel as it was at the time of the tests, November 1916). Nevertheless it was calculated that the added capacity with the combination fuel was obtained at 50 per cent less investment than would have been required with the coal.

Considering the situation from an operating standpoint the company obtained 31 per cent added capacity with an 8 per cent increase in the cost of producing a pound of steam. With the increased cost of coal becoming operative, this increase in cost over the cost of coal to produce a pound of steam would be offset.

The original article gives also a set of curves showing points at which combination coal and gas firing is economical. Another illustration in the original article shows two boiler-meter records of tests, one where coal alone was burned and another where gas and coal were fired in combination. (*Electrical World*, vol. 70, no. 2, July 14, 1917, pp. 52-54, 4 figs., *e*)

The Value of Peat Fuel for the Generation of Steam, John Blizard

Report forming the third and last of a series comprising the investigation undertaken some years ago by the Department of Mines of the Dominion of Canada to determine the value of peat fuel for the production of power. The former reports, entitled Utilization of Peat Fuel for the Production of Power, and Peat, Lignite and Coal, dealt mainly with the production of power through the media of gas producers and internal-combustion engines, while this report sets forth the results obtained with peat when burned on the grate bars of two distinct types of steam generators.

Results show that under favorable conditions and circumstances peat fuel can be economically employed for the production of power by steam, but the controlling factor which determines the feasibility of using peat fuel for steam generation is the cost of producing this form of fuel and delivering it to the steam plant in a sufficiently dry state. Not only this cost of peat fuel delivered to the plant must be less than that of a quantity of good steam coal equivalent in heating value, but it is important to bear in mind that peat fuel, as commercially produced today, is much bulkier than coal equivalent in heating value. Hence, the problem of storage of peat fuel assumes important proportions.

Speaking generally, it is safe to say that peat fuel for steam-raising purposes cannot compete with good steam coal costing \$5 and less per ton. It appears, therefore, that in the majority of cases the more economical method of procedure with respect to peat utilization is the conversion of the peat fuel into a combustible gas which can be burned in a gas engine in this form, or used for the different heating furnaces in metallurgical work.

The above is taken from a preface to the investigation written by B. F. Haanel, Chief Engineer, Division of Fuels and Fuel Testing of the Department of Mines, Canada.

The trials themselves, described in the present report, were made partly on a Babcock & Wilcox water-tube boiler and partly on an internally fired boiler of portable locomotive type. The fuel used was manufactured by the Anrep process and had a moisture content of 16 to 20 per cent, which is rather low for this class of fuel. Hence, care should be taken when estimating the steaming properties of peat to allow for this fact. Further, the peat was of excellent quality, contained only a small percentage of dust, and throughout the series was hand-fired by an experienced fireman.

From tests on the water-tube boiler, conclusion is drawn that the most efficient grate bar would be one having an air space sufficiently large to permit the ash to fall through without taking an undue proportion of combustible with it.

It was also found that the ratio of free oxygen to combined oxygen in the flue gases increased with increased combustion per square foot of air opening. Probably, because as the draft increased, the supplementary air supply over the bars also increased, or it was the smaller air spaces that decreased the facility for the removal of ash by gravity, thus leaving the combustible portion of the fuel less accessible to the air.

As regards the flue-gas losses, the contents of carbon monoxide appear to be unusually high, and in addition to that, other gases were present. In fact, it may be taken as a rough approximation that the unused energy in these gases amounts to one-half of that remaining latent as carbon monoxide.

On the whole, the peat used proved to be a good fuel, easily handled and giving no trouble due to clinker or ash. It burned with a long flame and considerable light-colored smoke. The best results were obtained with the fuel consumption of 15 lb. per sq. ft. of grate, and the highest efficiency was obtained with the fuel highest in moisture content. Efficiency, however, was, on the whole, low, which may be attributed in part to the superheated steam in the flue gas, as well as losses due to unburned hydrocarbons and hydrogen. In fact, the total loss due to unburned gases was so high as to warrant the design of a large specially constructed combustion chamber in order to insure more complete combustion when burning this fuel.

Table 1 gives a synopsis of the results of trials with the water-tube and fire-tube boilers, respectively. (*Canada Department of Mines, Mines Branch Bulletin No. 17*, Ottawa, 1917. 42 pages, illustrated. *eA*)

TABLE 1 RESULTS OF TRIALS OF BOILERS FIRED WITH PEAT FUEL

	Water-tube Boiler			Fire-tube Boiler		
No. of Trial	71	72	73	83	84	85
Net calorific value of fuel as fired, B.t.u. per lb.	7490	7490	6990	7130	6970	7110
Peat fired per hour, lb.	476	586	569	160	214	341
Peat fired per sq. ft. of grate surface per hour, lb.	20.5	15.5	15.0	17.7	23.8	37.9
Equivalent evaporation per hour from and at 212 deg. fahr., lb.	1950	2322	2250	621	802	1054
Equivalent evaporation per hour per sq. ft. of heating surface, lb.	2.88	3.43	3.32	2.89	3.73	4.9
Pounds of dry flue gas per lb. of peat	12.4	9.8	11.1	9.8	9.1	6.5
Temperature in flue leaving boiler, deg. fahr.	720	760	715	690	690	750
Equivalent evaporation from and at 212 deg. fahr. per lb. of peat as fired, lb.	4.10	3.96	3.95	3.89	3.74	3.09
Thermal efficiency of boiler, furnace and grate, based on the net calorific value, per cent	53.1	51.3	54.8	52.9	52.1	42.2

Hydraulics

The Friction of Water in Iron Pipes and Elbows, F. E. Giesecke

Data and description of a series of experiments carried out by the Division of Engineering, Bureau of Economic Geology and Technology of the University of Texas, in November 1916, to determine the friction of water in standard American pipes and fittings.

The data are presented in the form of curves, expressing the friction of flow of water in various pipes at different velocities.

Equation showing the relation between the friction (h) and the velocity (v) for clean iron pipes ranging in size from ½ to 3 in. when the water has a temperature of about 68 deg. fahr. and flows at velocities up to 3 ft. per sec.:

$$h = 0.00685 \frac{v^{1.77}}{d^{1.275}}$$

Friction of water at temperature of about 68 deg. fahr. in one standard short-radius steam elbow:

$$h = 0.0141 \frac{v^{1.96}}{d^{0.26}}$$

From Fig. 5 the equations showing the relation between the friction and the velocity for 1¼-in. black pipe are for the line *GH* (below critical velocity)

$$h = 0.00925\ v^{0.87}$$

and for the line *HI* (above the critical velocity)

$$h = 0.004675\ v^{1.756}$$

Other pipes ranging in size from ½ to 3 in. were tested, the results plotted and the friction for 1 ft. of pipe was determined.

In order to derive an equation applicable to pipes of different sizes the coefficients and exponents of v in the equation

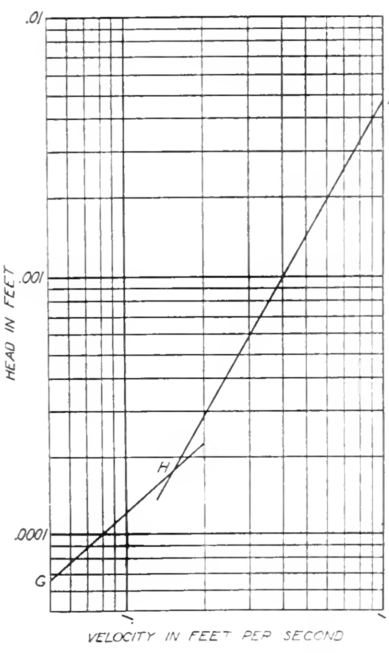

Fig. 5 Diagram Showing the Friction of Water in 1 Ft. of Pipe at Different Velocities

$h = kv^n$ were plotted, and from this diagram was derived the following approximate equation:

$$h = 0.00685 \frac{v^{1.77}}{d^{1.275}}$$

(A more accurate equation is given in the original article.) This equation applies to water having a temperature of about 68 deg. fahr. flowing through clean iron pipes ranging in size from ½ in. to 3 in., and with velocities up to 3 ft. per sec.

A series of tests was also made to determine the effect of galvanizing and incrustation on the friction in pipes and equations were derived. From these tests it appears that the exponent of v in the expression for h increases with the roughness of the interior surface of the pipe. On the other hand, tests with water at temperatures varying from 70 to 140 deg. fahr. showed that the friction decreases as the temperature increases, and that the decrease is due to a change in the coefficient of v rather than to a change in the exponents.

An interesting series of tests was made to determine the friction in an elbow (Fig. 6). This friction may also be represented by the expression $h = kv^n$. The two heavy lines show, as nearly as possible, the average values of k and n, and from them the expression

$$0.0141 \frac{v^{1.96}}{d^{0.26}}$$

was determined as representing the friction of water at the

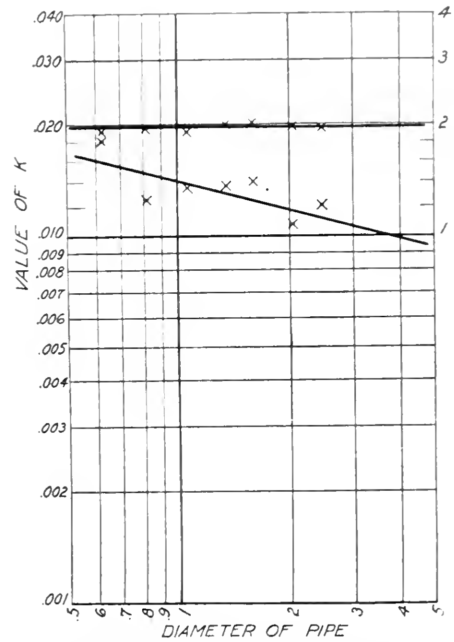

Fig. 6 Diagram Showing the Relations of Coefficients and Exponents of v for Elbows of Different Sizes

temperature of about 68 deg. fahr. in one standard short-radius steam elbow.

In the original article a diagram is given showing the number of feet of straight pipe equivalent in friction to one elbow for any velocity of flow.

A bulletin giving a full report of the tests will be issued by the University of Texas as early as possible and will be sent free to all persons requesting a copy so long as the supply lasts. (*Journal of the American Society of Heating and Ventilating Engineers*, vol. 23, no. 4, July 1917, pp. 587-594, 6 figs. *et*)

Hydraulic Billet Breaker

Description of a 200-ton hydraulic billet breaker recently erected at a works in Yorkshire.

As shown in Fig. 7, the present machine, which is designed for breaking steel bars of 55 tons tensile strength into 16-in. lengths, has top and bottom notching blades provided in the form of an equilateral triangle, so that when worn they may be reversed in the dies and thus give three cutting edges. In this way the necessity for nicking the top side and then turning the billet over to break it is eliminated.

The bar to be cut is fed over a spring-supported roller, which carries it clear of the bottom knife and allows it to be fed up to the adjustable stop at the dead end. The ram which carries the top notcher is 20 in. in diameter and has a stroke of 12 in., with a working pressure of 1500 lb. per sq. in.

After the bar has been notched on both sides by a stroke of the ram, the lower knife, which has an easy fit in its die, is withdrawn by means of the handle and the bar is broken by a second stroke of the ram. The machine has an output capacity of 38 billets per hour. When dealing with particularly soft material it might be found necessary to turn the bar, so as to notch it on all four sides.

Attention is called to the fact that the operating lever is placed at the side and not at the front of the machine as in earlier designs. The ram is actuated direct from the pump, which is of the vertical three-throw type with plungers $2\frac{1}{2}$ in. in diameter by 6-in. stroke. It is driven by a 25-hp. motor through a double-helical gear enclosed in an oiltight casing.

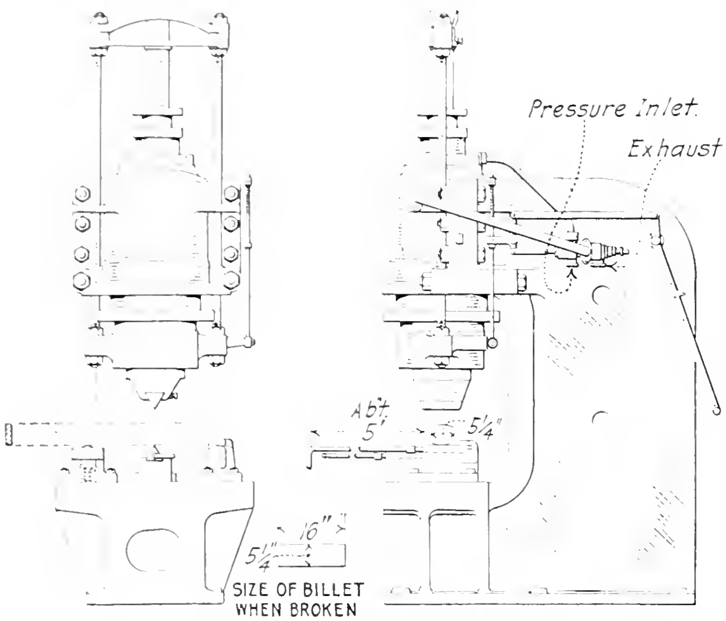

FIG. 7 BRITISH 200-TON VERTICAL HYDRAULIC BILLET BREAKER

The pump plungers are fitted with a weight-controlled relief valve, and this weight is so arranged that it may be thrown over and thus relieve the pressure of the pump plungers when the breaker is not in actual duty. In this latter connection the writer mentions, however, that a serious defect in the use of this reliever device lies in the fact that experience has shown that such devices are seldom made proper use of so long as their neglect does not interfere with the proper operation of the plant. (*Page's Engineering Weekly*, vol. 31, no. 670, July 13, 1917, pp. 17-18, 2 figs., *d*)

Machine Shop

SURFACE FACTOR IN QUENCHING EXPERIMENTS. Lawford H. Fry, Mem.Am.Soc.M.E.

Data of experiments carried out with the purpose of studying the rate of cooling in various quenching media and of connecting the rate of cooling with the physical properties obtainable in quenched and tempered forgings.

The main series of experiments was carried out with two

> ***In quenching, the rate at which heat is lost per unit of surface is determined by a quenching medium, but the physical properties of steel are determined by the rate at which temperature is lost, that is, the rate at which heat is lost per unit of weight.***
>
> ***The rapidity of cooling depends on:***
>
> ***a—Intimate contact between fluid and object to permit transfer of heat from object to fluid;***
>
> ***b—Free flow of fluid to remove heated or vaporized fluid from the surface of the object.***

locomotive driving axles, which were drilled so that a pyrometer could be inserted and the temperature of the axle measured continuously during the process of quenching. One axle was 11 in. in diameter and forged solid. The other was 12 in. in diameter and bored longitudinally with a 3-in. hole. The quenching media experimented with were air, water, and heavy oil of 26 deg. B. gravity, a light oil of 29 deg. B. gravity, and three strengths of a cutting compound dissolved in water. This cutting compound, which was composed of mineralized lard, oil and soft soap, was used in solutions of 50 per cent, 33 per cent and 25 per cent. The cooling curves for twelve experiments are given in Fig. 8. Of these twelve experiments eight were made with a solid and four with a bored axle.

These curves indicate that the bored axle cooled more rapidly than did the solid axle in the same medium.

Further tests with a small test piece indicated that in a given medium the heat is given up by the big axle and the small test piece had practically the same rate in B.t.u. per sq. in. of surface, which makes it probable that fairly accurate information as to the quenching properties of a medium can be obtained from small-scale experiments..

It must be remembered, however, that the physical properties of steel are determined not by the rate at which heat is lost per unit of surface, but by the rate at which heat is lost per unit of weight, that is, by the rate at which temperature is

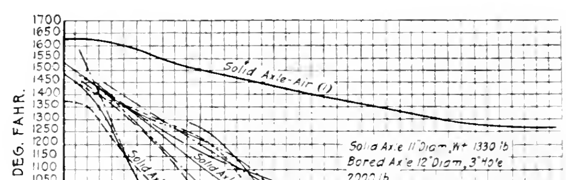

FIG. 8 COOLING CURVES IN QUENCHING EXPERIMENTS

lost. From data presented in the paper it appears that the rate at which heat is lost per unit of surface is determined by the quenching medium, while the physical properties of the steel are determined at the rate at which temperature is lost. Furthermore, the rate of temperature loss depends both on the quenching medium and on the form of object quenched, the latter being the more important factor.

The writer, together with some other investigators, claims

that the only scientific method of defining heat treatment in connection with physical properties is not to speak of "water quenching" or "air cooling," but to give the rate of temperature loss over a given range. To show how indefinite is the expression "air-cooled," the writer cites from the present test the fact that the test piece lost heat at the rate of 120 deg. per min. Hence, although the rate of cooling would be somewhat slower if it were averaged over a longer temperature range so as to include the recalescent period, still the rate at which the test piece cools in the air is of the same order as the rate at which the axle cools when quenched in water. Consequently the physical properties of the "air-cooled" test piece and the "air-cooled" axle will differ as widely as the properties of the "air-cooled" axle and of the "water-quenched" axle.

As regards the quenching speeds and composition of media, the experiments have not been complete enough to establish a theory of quenching action, but justify the conclusion that to have rapidity of cooling it is necessary to have first an intimate contact between fluid and object to permit transfer of heat from object to fluid, and second, free flow of fluid to remove heated or vaporized fluid from the surface of object.

A noteworthy feature is the great acceleration in cooling produced by a forced agitation of solution. Likewise the more rapidly cooling system produced with a light oil in comparison with heavy oil is evidently due to the greater fluidity of the former which enables more rapid convection currents to be set up and carry off the heat. (Paper before the Annual Meeting of the British Iron and Steel Institute, London, May 3-4, 1917, reprinted in the *American Drop Forger*, vol. 3, no. 7, July 1917, pp. 239-241. 1 fig., *e*)

Measurements

An Aneroid Calorimeter for Specific and Latent Heats, Nathan S. Osborne

The unstirred type of calorimeter has been embodied with important refinements in an instrument especially designed for determinations of specific heat and latent heat of refrigerating media. Heat developed and measured electrically is distributed automatically to the calorimeter and contents whose temperatures are measured by a platinum thermometer. Heat from other sources is excluded by a null method.

The calorimeter is adapted for use between minus 50 deg. and plus 50 deg. cent. In experiments where the measured heat added is used either to change the temperature of the contents or to evaporate a portion of the contents withdrawn as superheated vapor; in the first case, the specific heat of the liquid, and in the second, the latent heat of vaporization being obtained when proper corrections are made. (*U. S. Bureau of Standards*, Scientific Paper No. 301, advance abstract)

The Relative Sensibility of the Average Eye to Light of Different Colors and Some Practical Applications to Radiation Problems, W. W. Coblentz and W. B. Emerson

This paper gives data on the relative visibility of radiation of the average eye, based upon a group of 130 observers. The data were obtained by means of a flicker and an equality-of-brightness photometer. The energy evaluation of the light stimulus was made with great care.

The point of maximum visibility of the average eye is at $\lambda = 0.5576\mu$. A mathematical equation is given of the average visibility curve, which is applied in calculating the luminous energy emitted by a black body at various temperatures and the mechanical equivalent of light. The eye responds to light having an intensity less than 1×10^{-16} watt per cm². The paper describes tests on diffused light and on a physical photometer. A screen is described which transmits radiations proportional to the average eye. (*U. S. Bureau of Standards*, Scientific Paper No. 303, advance abstract)

Mechanics

Effect of Countershaft Speed Ratio on Power and Torque, Prof. A. Lewis Jenkins, Mem.Am.Soc.M.E.

A study of the two different combinations of countershaft speeds, back-gear ratios, and cone-pulley ratios for a pump-driven machine. An example is worked out for each combination, showing the belt speeds, horsepowers and spindle torques.

In the operation of cone-driven machines the consecutive spindle speeds may be obtained in a number of different ways by effecting various combinations of countershaft speeds, back-gear ratios and cone-pulley ratios. But there are two ways in use which require different cone-pulley ratios and ratios of countershaft speeds, and these are as follows:

First, the consecutive spindle speeds are obtained by starting with the slow countershaft speed, the largest back gear and the belt on the largest step of the head cone, which gives the first cone-pulley ratio. The change from the first, or slowest, to the second spindle speed is accomplished by merely changing the countershaft speed from slow to fast. For the next change of speed it is necessary to change the belt from the first to the second step on the head cone and change the countershaft speed from fast to slow. The fourth speed is then obtained by merely changing the countershaft speed from slow to fast.

The next case is where the back-gear ratios are used in the same way as in the preceding case, but the countershaft speeds and steps on the cones are not.

The slowest spindle speed is here obtained by using the slowest countershaft speed and the largest step on the head cone. In changing from the first to the second and from the second to the third spindle speeds it is only necessary to shift the belt from one step to the next. The fourth speed is obtained by using the fast countershaft speed with the belt on the largest step of the head cone, while the next two spindle speeds are obtained by using the second and third cone-pulley ratios with the fast countershaft speed.

The article gives formulæ for the back-gear ratios, cone-pulley ratios for duplicate cones and for the countershaft speeds.

An example is worked out numerically and covers the determination of the back-gear, cone-pulley and countershaft speed ratios for a machine of given dimensions having three steps on the cone-pulley and two back-gear reductions. In this connection the comparative merits of the two systems outlined above are discussed. (*American Machinist*, vol. 47, no. 2, July 12, 1917, pp. 49-51. 3 figs., *(p)*)

Railway Engineering

Brick-Arch Tests, Pennsylvania Railroad

Data of tests made by the Pennsylvania Railroad to show the value of the brick arch as a means of conserving fuel. These tests were made in Altoona on a Mikado-type locomotive.

The boiler equipment was of the Security sectional type. All tests were hand fired, the fuel used being Jamison coal, bituminous, high volatile, sized by being passed over a screen having 1½-in. openings. The screening and the use of coal from a single mine were resorted to, because preliminary tests had demonstrated the need of uniformity in the size of coal for the test.

On the whole, the tests have demonstrated marked advantages which can be ascribed to the use of the arch, summarized in the report as follows:

a The maximum evaporation when using high volatile coal was increased [illegible] per cent by the use of the arch.

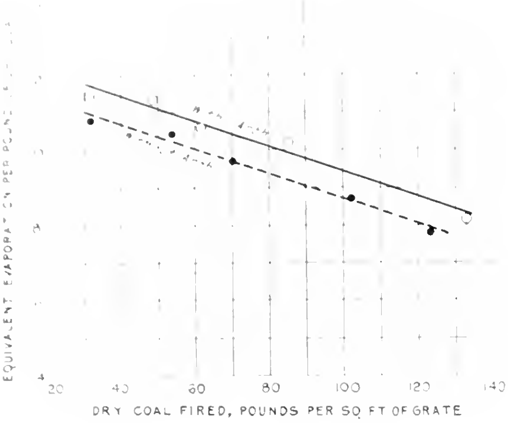

Fig. 9 Rate of Evaporation Per Pound of Coal, Brick-Arch Test

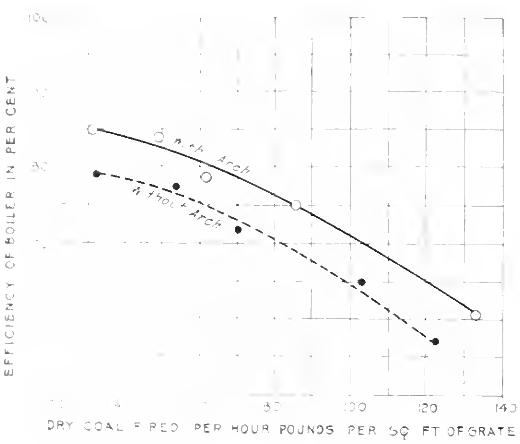

Fig. 10 Rate of Firing and Efficiency of Boiler, Brick-Arch Test

b With the arch a lower smoke density is measured by the Ringelmann scale.

c The arch increased the evaporation per pound of coal, and for ordinary rates of working this increase of evaporation represents an economy in coal of from 6 to 8 per cent.

This effect of the arch on evaporation was evident at all rates of combustion, as shown by Fig. 9. At maximum capacity the boiler when equipped with the arch was capable of evaporating 15.5 per cent more water than when without it.

A higher boiler efficiency was made possible by the arch at all rates of evaporation. This is shown in Fig. 10. When plotted against the combustion rate, the factor of boiler efficiency shows an increase ranging between 6.9 and 11.6 per cent, with a rate of firing varying from 35 to 120 lb. of dry coal per sq. ft. of grate per hour. An examination of the values obtained between the limits common to road service indicate improvement under these conditions of from 7 to 8½ per cent. The report draws attention to the fact that other experimenters have found that the arch tubes alone, because of the added surface and improved circulation, afford improvement to the extent of about one per cent for each tube involved.

Because of the conditions under which the tests were made, that is, at fixed speed and cut-off, no noticeable economy was observed in the operation of the engine, but there was an increase in the power developed consequent upon the larger volume of steam flowing. On the basis of drawbar pull, it was found that at speeds above 8 m.p.h. the locomotive when equipped with the arch had an appreciable advantage. This advantage, measured at the maximum power developed, which was at the speed of 29 m.p.h., amounted to an increased drawbar pull of 2066 lb., or 6.4 per cent. (Pennsylvania Railroad Test Department Bulletin No. 30, abstracted through the *Railway Review*, vol. 61, no. 5, August 4, 1916, pp. 137-139, 3 figs., *e*)

Steam Engineering

Condenser-Tube Corrosion, William Ramsay

A general discussion of the subject, together with data of observations and experiments made by the writer.

The writer does not ascribe much value to analyses of the defective tubes of a condenser after a breakdown. The analysis itself is a simple matter, but since the corroded matter has disappeared and the tube adjacent to the corroded part is, as a rule, normal, it does not give much material for the explanation. Further, the examination of the residue seldom points to anything useful, because the corrosion product contains the metals as basic chlorides, carbonates, oxides, or even sulphates, and much of this product is washed away in both soluble and insoluble form.

The writer made a number of experiments, many of which were abortive. The chief difficulty of experiments of this nature lies in the impossibility of reproducing actual working conditions. Even model condenser arrangements in which the same water is circulated many thousands of times failed to give the desired information. Such water may lose its corrosive properties, or, perhaps, become more corrosive with continued use, and the results are not likely to be conclusive.

The nature of brass corrosion is mainly, if not entirely, electrolytic in character, assisted by the fact that the commercial brasses are not homogeneous bodies, but are a kind of conglomerate.

Corrosion of a condenser tube may be said to commence from the moment it is put into use, and the extent to which it proceeds depends upon such factors as composition, time, temperature, water, etc.

The effect of corrosion in condenser tubes is varied. Copper and zinc may be removed uniformly from the surface, or, what is more commonly the case, zinc is dissolved out, leaving the copper or a copper-rich material as a coherent film, the original dimensions of the tube being nearly preserved. This is known as dezincification. In the case of the 60:40 tubes, the action takes place between the α and β constituents, and may proceed to completion, the tube retaining its original dimensions and to the naked eye preserving the appearance of a solid copper tube. On microscopic examination, however, it is seen to consist of coppery material, preserving the form of the α constituent, the space previously occupied by the β

being more or less filled by corrosion products, or possibly quite empty. In the case of 70:30 tubes, or Admiralty alloy, the action is probably somewhat different. Owing to some slight inequality in the composition, the equilibrium of the brass becomes upset and a more or less continuous film of copper results; electrolysis then takes place between the copper and the adjacent brass, resulting in a gradual concentration of copper. With these tubes dezincification is, as a rule, superficial.

Dezincification in itself is not a simple process. If some of the copper was in the solution, it may be redeposited as metallic copper on the brass, with an accumulative amount of zinc going into solution. The writer has proved that cuprous and cupric chlorides, oxide of copper and, in fact, most copper compounds are capable of depositing metallic copper on brass. The action of basic chloride of zinc is less clear, but on painting tubes with this material and immersing them in warm sea water, a distinct coppery stain results after some time. Dezincification may, therefore, at times even become protective.

It is an interesting fact that, if a portion of the coppery film be removed so as to expose the brass, it does not immediately become recoated with copper. A tube which had been dezinced to a depth of less than 1/500 in. was taken, and a small patch about ¼ in. sq. removed with fine emery paper, without appreciably altering the thickness of the tube. On immersing it in sea water kept warm, the brass rapidly corroded at this point until, in about a month, it was about 1/32 in. deep; copper then gradually encroached on the brass and stopped the action.

From this the writer proceeds to discuss the case of the so-called laminations in condenser tubes, due to defects in the manufacture of tubing, such as spills or blowholes in the original casting. On opening them up they are seen to be coated with oxide of copper, which, on immersing in sea water, is gradually reduced to the metallic state. This is probably the initial stage of electrolytic corrosion. Sooner or later the corroded lamination breaks away, exposing fresh lines of yellow brass. The following experiment was carried out to test the truth of the above. An Admiralty tube which showed indications of lamination was immersed in estuary water, which was changed almost every day over a period of more than two years, the containing flask being kept at a temperature of about 110 deg. to 150 deg. fahr. by means of an electric heater. After a few weeks the tube was completely coppered and the suspected lamination showed unmistakable signs of opening out. In about six months it had corroded away to a measurable extent, and several other lines of laminations, which had not been suspected, showed themselves. Throughout the test it was noticed that bubbles of gas adhered tenaciously to the laminations and the sharp edges of the tube. During the corrosion the lamination presented a varying appearance, at one time showing black lines, which cleared up to yellow brass or filmed over with copper through which minute specks of brass were visible, but at all times the action was greatest at the lamination and edges.

Likewise, due to defects in manufacturing, there are isolated holes in what may otherwise be perfect tubes. It is the opinion of the writer that these holes act in the capacity of corrosion centers.

The writer describes several sets of experiments, indicating that the strongest corrosion took place at, or near, the point of contact between two metals. Even metals, such as iron, zinc and lead, which are electropositive to brass, behave in this manner, which may be due to copper being redeposited on the foreign matter. It is noteworthy, in this connection, that magnetic oxide of iron, or metallic iron, coated with this oxide is sometimes electropositive, and at other times electronegative with reference to brass.

A form of corrosion of which the writer has definitely traced the cause is that which attacks the inlet ends for a few inches immediately beyond the tube plate. Here the cold circulating water, on becoming warm, deposits its dissolved gases; the part in the tube plate being kept cool, escapes this particular action, but just beyond this bubbles of CO_2 and air adhere to the tube, causing round each a ring of corrosion which eventually takes the form of a horseshoe, the open ends of which point in the direction of the water flow. This type of defect is most certainly due to the main condenser being used in harbor for the auxiliary machinery, when the smaller volume of steam does not necessitate the full-power circulation, and the friction of the water is insufficient to sweep away the deposited gases. Where an auxiliary condenser is used for port service this defect is obviated. Several rivers and harbors, and canals especially, have an evil reputation in this respect, all being more or less foul with sewage, while those with a good tidal scour are less objectionable. The accelerating effect of sewage, CO_2 and ammonia is well known.

In the original article is given a photograph of an opened-out tube which has suffered from this type of corrosion. It shows that, although the part in the tube plate is corroded, it has escaped the typical horseshoe action. The vessel from which this tube was taken was known to berth in a very dirty harbor. Dezincification is general all over the tube, and in the middle of each horseshoe, but where the corrosion is severe the brass remains yellow. This seems to point to the electrolysis between the separated copper and the brass.

There is another type of corrosion which affects the ends of the tubes and which may be found in any part of the condensers, and may occur singly or in groups. The extreme ends of the tubes are eaten away in the ferrules, which also may be involved; and in this case a curious accommodation between tube and ferrule often takes place, the more corroded part of the one fitting into the less affected part of the other, almost as if the action ceased when the pressure between the two had been relieved. This is most probably the case, since in cases of this type the writer has almost always observed that the tubes had been crushed or distorted by the ferrule. Physical condition as a factor in brass corrosion is fairly well established, and this seems a case which meets this theory. A condenser is generally tubed by several men, each taking a certain section or group of tubes, and it is not unlikely that one worker may have exerted such force as to bruise his tubes. This probably explains why such corroded ends generally occur in groups. (*Engineering*, vol. 104, no. 2689, July 13, 1917, pp. 40, 44-46, 7 figs., *eA*)

Thermodynamics

The Latent Heat of Steam, Frank B. Aspinall

The writer starts by giving the following definitions of terms:

Steam is that which exists when absolutely no water and absolutely no superheat is present.

The *total heat of steam* is the exact quantity of heat present when absolutely no water and absolutely no superheat are present.

The *latent heat of steam* is the exact quantity of heat required to convert water from the form of water completely into the form of steam at the same temperature and pressure

as the temperature and the pressure of the water converted into the steam.

Heat latent is the varying heat latent when varying mixtures of steam and water are present.

The *steam volume* is the maximum volume which can be present without superheat being present.

The writer states that when he analyzed hundreds of indicator cards he noticed facts which were unexplainable, unless it be admitted that steam at high pressures containing absolutely no water and absolutely no superheat carried more heat and had a smaller volume than the steam tables stated.

A series of measurements was therefore made to ascertain the maximum heat and maximum volume which could be present without superheat being present, and this was the result:

The maximum heat which could be latent, or the latent heat of steam, was found to be constant, at a value nearly, if not actually, 970.13 B.t.u.

A steam volume multiplied by a steam pressure is constant, if steam is accepted as that which exists when absolutely no water and absolutely no superheat are present, the value stated in cubic feet and pounds absolute being nearly, if not actually, 399.84.

From these two constants the following conclusions were arrived at in regard to the steam tables:

The values stated for the total heat at atmospheric pressure apply to wet steam, the wetness increasing as the pressure increases. The values stated for the total heat at below atmospheric pressure apply to the superheated steam, the superheating increasing as the pressure decreases.

The values stated for the latent heat at above atmospheric pressure apply to the heat latent in mixtures of steam and water, the water increasing as the pressure increases.

The values stated for the latent heat at below atmospheric pressure apply to neither latent heat nor heat latent.

The values stated for the volumes at above 25 lb. absolute apply to superheated steam, the superheat increasing as the pressure increases.

The values stated for volumes at below 25 lb. absolute apply to wet steam, the wetness increasing as the pressure decreases.

The values are therefore not only not comparable in themselves, but are also not comparable to each other.

The late Dr. Silvanus Thompson was instrumental in having the Finsbury Technical College in London carry out, under the present writer's supervision, the determinations described in the article here abstracted.

The article describes in detail the conditions which were to be fulfilled during these tests, the method and apparatus used, observations and numerical results and the deductions arrived at. The following definitions were adopted for the terms employed:

The latent heat of steam is the amount of heat required to convert water, at a definite temperature and pressure, completely into steam at the same temperature and pressure as the water.

The sensible heat in steam is the heat in the water at the definite temperature and pressure at which it is converted into steam.

The total heat of steam is the latent heat plus the sensible heat or the maximum heat which can possibly be present without superheat being present.

Wet steam is a mixture of steam and water in some form. The total heat present is therefore less than that which would be present if the water had been completely converted into steam.

Steam is all steam, the total heat present being the exact amount required for all the water to be converted completely into steam.

Superheated steam is all steam, the total heat present being more than the amount required at the given pressure and temperature for all water to be converted into steam.

The following formula was used to work out the latent heat of steam:

The latent heat of steam at the pressure P at the point $B =$

$$\frac{W(t_1 - t_2) - w(T - t_1) \pm j}{w}$$

P. As the supertemperature was so low, the observed pressure was accepted as the pressure of pure steam, but if the steam had been very highly superheated, a correction would have to have been made for the supertemperature.

W. In the first trials. The water present at commencement of the second blow + the water value of the metal.

In the second, third and fourth trials. The water present when the pipe was dropped into the water + the water value of the metal + the water value of the wood.

w. The actual weight present at the finish of the trial, minus the actual weight present at the commencement of the trial.

T. The mean corrected observed temperature of the thermometer in the long temperature well — the mean supertemperature.

t_1. The mean corrected observed temperature of the condensing water at the finish of the trial, as shown by thermometers, T.I., T.II., T.III. + the temperature the condensing water would have gained if it had not lost or received heat due to the surrounding air.

t_2. The mean observed corrected temperature of the condensing water at the commencement of the trial, as shown by thermometers T.I., T.II., T.III.

j. The difference between the superheat in the steam due to the supertemperature and the heat radiated from the lagged and bare pipe beyond the controlling valve admitting steam to the condensing water to within 1½ in. above the maximum height of the water in the wooden vessel.

It will be noticed that the writer, like Southern and Regnault, makes no correction for possible changes in the specific heat of the boiler water. It appears, however, from the results of James Watt, Southern, and the writer, that the specific heat of water is constant *when water is subjected to the conditions present when a boiler is making steam.*

The method employed to determine the water value of the wooden vessel by the method of mixtures is described in detail.

Among other things, it has been found that even although extreme care was taken to prevent the steam from containing water just before it was wiredrawn, the small supertemperature obtained for such a large drop in pressure shows that water must have been present. There seems no other explanation than to conclude that *water can be present in steam in some form which is not a mechanical mixture.* This view also seems to be confirmed by the fact that for equal differences of pressure higher supertemperatures were usually obtained at 50 lb. than at 100 lb., which apparently shows that steam at a higher temperature can contain more water than at a lower temperature. The experiments seems to support the conclusion that *steam has a dewpoint like air.*

The Finsbury value for the latent heat of steam, or the

exact quantity of heat required to convert water from the form of water completely into the form of steam at the same temperature and pressure as the temperature and pressure of the water converted into the steam, is 969.67 B.t.u., a constant, per 1 lb. of steam. The writer takes, however, 969.90 as the constant latent heat of steam. This figure is the mean of the Blackheath value 970.13 and the above Finsbury value.

The writer proclaims the following basic laws:

It is the quantity of water present and not the temperature present which determines the quantity of heat which is latent.

The quantity of heat latent is a variable if water is present, because the maximum quantity of water which can be present increases as the pressure increases.

The evidence collected by the present writer leads him to believe that the heat latent when absolutely no water is present, or the latent heat of steam, is nearly, if not actually, 970 B.t.u. at all pressures.

Further, provided absolutely no water and absolutely no superheat are present, the pressure multiplied by the volume is always nearly, if not actually, 400.

The writer concludes by calling attention to the fact that James Watt distinguished between latent heat and heat latent, and believes that all the trouble has arisen owing to Regnault not making this distinction. (*The Engineer*, vol. 124, nos. 3210, 3211, 3212, July 6, 13 and 20, 1917, *tA*)

Ventilation Standards and the Synthetic Air Chart, Dr. E. V. Hill

The writer claims that one of the problems of modern ventilation is not so much *how* to accomplish the desired need, but *how to know* when that end has been attained. In other words, the need is for improvement not in mechanical equipment, but in methods of testing to determine with greater accuracy what the equipment accomplishes, and more than all else, satisfactory standards by which conditions may be compared. The development of a satisfactory air-condition test record, however, is made difficult through the fact that combinations might occur that when plotted would be misleading. Such a test record must cover at least temperature, air movement and humidity, and there is a definite relation between the *variations* of these elements that it is difficult to show accurately on the chart.

In fact, after giving this matter considerable study, the writer came to the conclusion that more definite information regarding the relations of temperature, humidity and air motion to each other in their bearing on comfort must be secured before a workable chart could be designed. To do this a room in a factory building was equipped so that any combination of temperature, humidity and air motion could be maintained and their relations approximately determined.

On the whole, it has been found that, first, comfort depends upon air conditions that allow the normal heat losses from the body without the undue exercise of heat-regulating mechanism. Second, other things being equal, the heat loss is approximately constant if the wet-bulb temperature is constant. And third, the comfortable wet-bulb temperature increases with the air motion.

On this basis two synthetic air charts were developed, of which the second, introducing air-motion curves, is reproduced in Fig. 11. The theory on which the chart is based is that the factors which determine ventilation of a given space may be conveniently combined into three principal groups, as follows: (1) Temperature, humidity and air motion; (2) Dust, bacteria and odors; (3) Air supply and carbon dioxide.

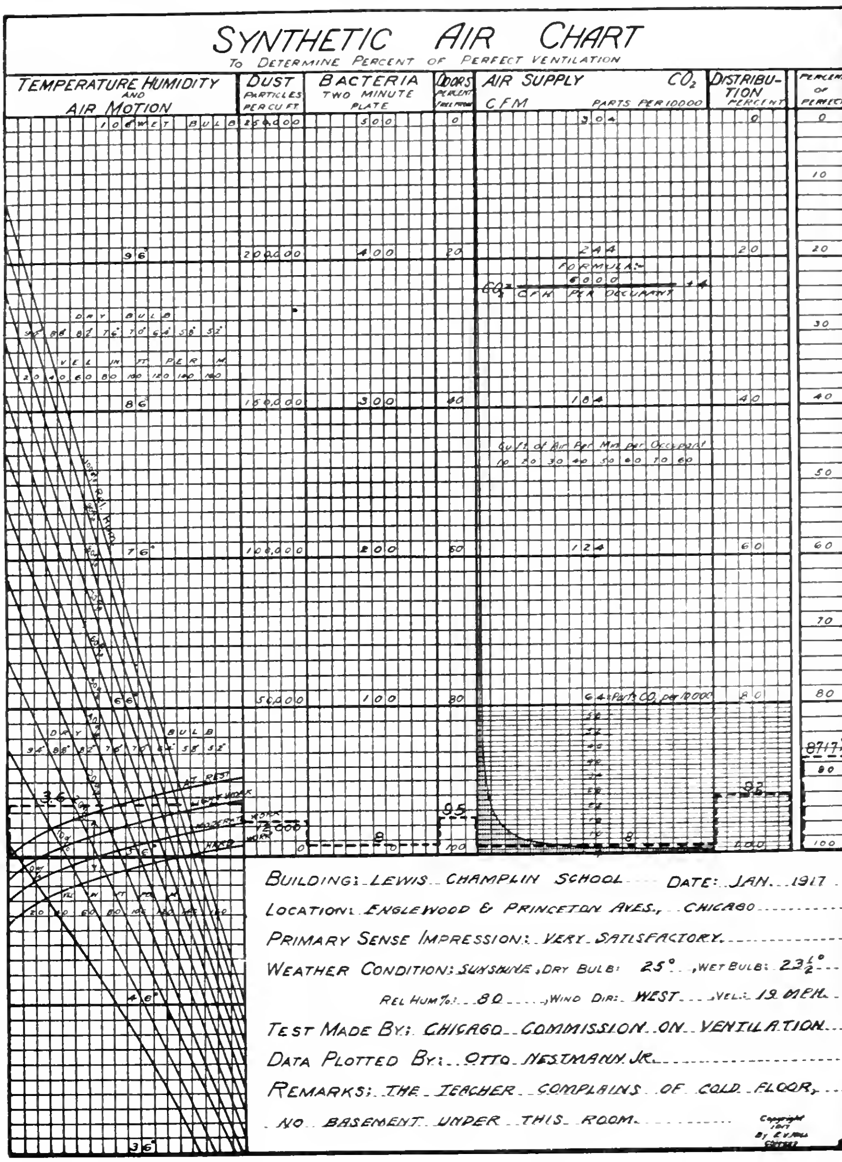

Fig. 11 Synthetic Air Chart

The use of the chart in Group 1 is as follows: From test data is noted the wet-bulb temperature. This is indicated by the horizontal line connecting this wet-bulb temperature and the appropriate air-motion curve. Next is noted from test data the air motion prevailing, and the appropriate air-motion curve is connected by a horizontal line with the wet-bulb that is desired for this velocity. The number of squares between these two horizontal lines across this portion of the chart is the amount of penalization. (*Journal of the American Society of Heating and Ventilating Engineers*, July 1917, p. 477, *ep*)

City Planning Progress; In the United States, 1917. Compiled by the Committee on Town Planning of the American Institute of Architects. Edited by George B. Ford assisted by Ralph F. Warner. The Journal of the American Institute of Architects, *Washington, D. C., 1917.* Paper, 8 x 11 in., 207 pp., 113 figs. $1.50. Gift of the publisher.

Compressed Air; Theory and Computations. By Elmo G. Harris. 2d ed., McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth, 6 x 9 in., 192 pp., 32 figs. $2. Gift of the publisher.

Compressed Air for the Metal Worker. By Charles A. Hirschberg. The Clark Book Co., *New York, 1917.* Cloth, 5 x 8 in., 321 pp., 294 figs. $3. Gift of the publisher.

Compressed Air Practice in Mining. By David Penman, M. Inst. M. E. J. B. Lippincott Co., *Philadelphia, 1917.* Cloth, 5 x 8 in., 221 pp., 113 illus. Gift of the publisher.

Contributions to Economic Geology, 1916. Part II—Mineral Fuels. U. S. Geological Survey. Bulletin no. 641. *Washington, 1917.* Purchase.

Council Bluffs, Iowa. Mayor's annual message with accompanying documents. 1914. Gift of Department of Finance and Municipal Accounts.

Determination of Nitrogen in Substances Used in Explosives. (U. S. Bureau of Mines. Technical Paper 160) *Washington, 1917.* Purchase.

Detroit, Mich., Department of Public Works. Annual Report (42d), 1916. *Detroit, 1916.* Gift of Department of Public Works.

The Disposal of Household Wastes. By Wm. Paul Gerhard. 3d ed. D. Van Nostrand Co., *New York, 1915.* Boards, 4 x 6 in., 195 pp., 4 figs. $0.50. Gift of the publisher.

Dyestuff Situation in the United States, Nov., 1915. U. S. Department of Commerce. Special Agents series, no. 111. *Washington, 1916.* Purchase.

East Orange, N. J. City Council. Annual Report. 1913-1916. Gift of City Clerk.

Electrical Measurements in Practice. By Malcolm Farmer. McGraw-Hill Book Co., Inc. *New York, 1917.* Cloth, 6 x 9 in., 359 pp., 230 figs. $4. Gift of the publisher.

Electric Railway Transportation. By Henry W. Blake and Walter Jackson. McGraw-Hill Book Co., Inc. *New York, 1917.* Cloth, 6 x 9 in., 487 pp., 120 figs., $5. Gift of the publisher.

Elementary Chemical Microscopy. By Emile Monnin Chamot. John Wiley & Sons, Inc., *New York, 1916.* Cloth, 6 x 9 in., 410 pp., 147 illus. $3. Gift of the publisher.

Elevations in Tennessee. Tenn. State Geological Survey. Bulletin 19. *Nashville, 1917.* Purchase.

Elliott's Weights of Steel. Computed by Thomas J. Elliott. The Penton Publishing Co., *Cleveland, 1916.* Leather, 6 x 9 in., 662 pp. $20. Gift of the publisher.

Engineering Index, 1884-1915. 14 vols. New York, 1885-1916 Gift of Cary T. Hutchinson.

Engineers' Club of Philadelphia. Directory, 1917. *Philadelphia, 1917.* Purchase.

The Essentials of American Timber Law. By J. P. Kinney. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 6 x 9 in., 279 pp. $3. Gift of the publisher.

Evansville, Indiana. Annual Reports, 1913, 1915, 1916. Gift of City Comptroller.

Evolution of the Steam Turbine in the Textile Industry, with Special reference to Mechanical Drives through Reduction Gears and the Economies of Large Units. By John A. Stevens. *Lowell, 1917.* Gift of author.

Farm Concrete. By K. J. T. Ekblaw. The Macmillan Co., *New York, 1917.* Cloth, 5 x 8 in., 295 pp., 77 figs., and 16 plates. $1.60. Gift of the publisher.

Farm Motors; Steam and Gas Engines, Hydraulic and Electric Motors, Traction Engines, Automobiles, Animal Motors, Windmills. By Andrey Potter. 2d ed., McGraw-Hill Book Co., Inc.. *New York, 1917.* Cloth, 6 x 9 in., 299 pp., 296 figs. $1.50. Gift of the publisher.

Federal Valuation of the Railroads in the United States. Circular communication to Chairmen of Valuation Committees with reference to Interstate Commerce Commission Order no. 20 . . . July 14, 1917. Gift of Clemens Herschel.

Federal Valuation of the Railroads in the United States. Statement prepared by H. C. Phillips, general secretary of the developments in connection with Federal valuation as of July 2, 1917. Gift of Clemens Herschel.

Fire Prevention and Protection. A Compilation of Insurance Regulations and Suggested Improvements in Building Construction. 3d ed. By A. C. Hutson. The Spectator Co., *New York, 1916.* Leather, 5 x 7 in., 777 pp., 129 illus. $1.25. Gift of the publisher.

Gas and Fuel Analysis for Engineers. By August H. Gill 8th ed. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 5 x 7 in., 145 pp., 20 figs. $1.25. Gift of the publisher.

Gas-Lighting and Gas Fitting: A Pocket Book for Gas Engineers, Gas Fitters, etc. By Wm. Paul Gerhard, 4th ed. D. Van Nostrand Co., *New York, 1913.* Boards, 4 x 6 in., 190 pp., 3 figs. $0.50. Gift of the author and publisher.

Geology and Mineral Resources of the Reefton Subdivision, Westport and North Westland Divisions. New Zealand. Geological Survey Bulletin no. 18. *Wellington, 1917.* Purchase.

Gloversville, N. Y. Common Council. Mayor's Annual Message with the Annual Reports. 1913. *Gloversville, 1914.* Gift of City Clerk, Gloversville.

Grand Rapids (Mich.) Board of Public Works. Annual Reports (42d-43d), 1915-16. Gift of Board of Public Works.

Gray's Plumbing Design and Installation. By William Beall Gray. David Williams Co., *New York, 1916.* Cloth, 6 x 9 in., 559 pp., 500 figs. $4. Gift of U. P. C. Book Co.

Heaton's Annual; The Commercial Handbook of Canada and Boards of Trade Register (13th Year). Heaton's Agency, *Toronto, 1917.* Cloth, 5 x 7 in., 518 pp. $1.25. Gift of the publisher.

High-Speed Internal Combustion Engines. By Arthur W. Judge. The Macmillan Co., *New York, 1916.* Cloth. 6 x 9 in., 350 pp., 217 figs. $5.50. Gift of the publisher.

House-Drainage and Sanitary Plumbing. By Wm. Paul Gerhard. 12th ed. D. Van Nostrand Co., *New York, 1907.* Boards, 4 x 6 in., 231 pp., 6 plates. $0.50. Gift of the author and publisher.

How to Study. By George Fillmore Swain. McGraw-Hill Book Co., inc., *New York, 1917.* Paper, 5 x 7 in., 65 pp. $0.25. Gift of the publisher.

Illuminating Engineering Practice. Lectures on illuminating engineering delivered at the University of Pennsylvania, Sept. 20-28, 1916, under the joint auspices of the University and the Illuminating Engineering Society. *New York, 1917.* Purchase.

Institute of Marine Engineers. Annual Reports (26th, 27th). *London, 1915, 1916.* Purchase.

Interborough Finance; Present and Future, Including Synopsis of the Financial Structure of Interborough Consolidated Corporation. Van Emburgh & Atterbury, *New York, 1917.* Leather, 6 x 9 in., 69 pp., 2 maps, 2 diagrams, Gift of the publisher.

Introduction to the Rarer Elements. By Philip E. Browning. 4th ed. John Wiley & Sons, Inc. *New York, 1917.* Cloth, 6 x 9 in., 250 pp., 6 figs. $2. Gift of the publisher.

Irrigation Works Constructed by the United States Government. By Arthur Powell Davis. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 6 x 9 in., 413 pp., 128 illus. $4.50. Gift of the publisher.

John Crerar Library. Annual Report (22d), 1916. *Chicago, 1917.* Gift of John Crerar Library.

The Life of Robert Hare: An American Chemist (1781-1858). By Robert Fahs Smith. J. B. Lippincott Co., *Philadelphia, 1917.* Cloth, 6 x 9 in., 508 pp., 1 por., 4 illus. $5. Gift of the publisher.

Lumber Markets of the East Coast of South America. U. S. Department of Commerce. Special Agents series no. 112. *Washington, 1916.* Purchase.

Macon, Ga., Annual Reports of Officers, 1913, 1916. Macon, Ga. *1913, 1916.* Gift of City Clerk.

McGraw Central Station List, 1917. *New York, 1917.* Purchase.

MacRae's Blue Book (Buying Guide). Vol. 8, 1917. MacRae's Blue Book Co., *Chicago and New York, 1917.* Cloth, 9 x 11 in., 1144 pp. $10. Gift of the publisher.

Maine Public Utilities Commission. Annual Report (2d), 1916. *Waterville, 1916.* Gift of Public Utilities Commission.

Mechanical Appliances, Mechanical Movements and Novelties of Construction. By Gardner D. Hiscox. 4th ed. The Norman W. Henley Publishing Co., *New York, 1917.* Cloth, 6 x 9 in., 396 pp., 1000 figs. $3. Gift of the publisher.

Mechanical Movements, Powers and Devices; A Treatise Describing Mechanical Movements and Devices Used in Constructive and Operative Machinery and the Mechanical Arts. By Gardner D. Hiscox. The Norman W. Henley Publishing Co., *New York, 1917.* Cloth, 6 x 9 in., 409 pp., 1800 figs. $3. Gift of the publisher.

Merchants' Association of New York. Supplement no. 33 for brief of arguments against public ownership. Nov., 1916. Gift of American Telephone & Telegraph Co.

Military Sketching and Map Reading. By Capt. Loren C. Grieves. U. S. Infantry Association, *Washington, D. C., 1917.* Cloth, 6 x 9 in., 95 pp., 32 figs. $1. Gift of the publisher.

Missouri Bureau of Geology and Mines. Biennial Reports of the State Geologist. 1917. Purchase.

The Modern Gas Tractor; Its Construction, Utility, Operation and Repair. By Victor W. Page, 2d ed. The Norman W. Hanley Publishing Co., *New York, 1917.* Cloth, 5 x 7 in., 504 pp., 225 figs. $2. Gift of the publisher.

Modern Milling: A Practical Manual on Milling Machines, Milling Accessories and Milling Operations. By Ernest Pull. The Macmillan Co., *New York, 1917.* Cloth, 6 x 9 in., 207 pp., 188 figs. $3. Gift of the publisher.

Monograph of the Foraminifera of the North Pacific Ocean. Pt. VI—Miliolidae. U. S. National Museum. Bulletin 71. *Washington, 1917.* Purchase.

Moody's Manual of Railroads and Corporation Securities.—Public Utilities. 1917. *New York, 1917.* Purchase.

Moody's Manual 1917—Industrials. *New York, 1917.* Purchase.

Moody's Manual Complete List of Securities Maturing, July 1, 1917–June 30, 1919. Vol. IV. *New York, 1917.* Purchase.

Montclair (N. J.) Town Council. Annual Report, 1911. Gift of City Clerk.

Motor Boats, Hydroplanes, Hydroaeroplanes: Construction and Operation with Practical Notes on Propeller Calculation and Design. By Thomas H. Russell. Charles C. Thompson Co., *Chicago, 1917.* Cloth, 5 x 8 in., 254 pp., 106 figs. $1. Gift of the publisher.

National Association of Railway Commissioners. Proceedings of the 28th Annual Convention, Washington, D. C., Nov. 14-17, 1916. *New York, n. d.* Purchase.

National Industrial Conference Board. Summary of report on workmen's compensation acts in the United States. April, 1917. Gift of Board.

National Tube Company. "National" Pipe Standards. *Pittsburgh, 1917.* Gift of National Tube Company.

Naval Architecture. By Cecil H. Peabody. 4th ed. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 6 x 9 in., 641 pp., 218 figs. $7.50. Gifts of the publisher.

Navigation Laws. Comparative study of principal features of the laws of the United States, Great Britain, Germany, Norway, France and Japan. U. C. Department of Commerce. Special Agents series no. 114. *Washington, 1916.* Purchase.

New Jersey Department of Conservation and Development. Annual Report for the year ending Oct. 31, 1916. *Trenton, N. J., 1917.* Gift of Department of Conservation and Development.

North Adams, Mass. City Clerk. Annual Reports. 1912-1916. *North Adams, 1912-16.* Gift of City Clerk.

Ohio Engineering Society. Report of the 38th annual meeting, 1917. *Norwalk, 1917.* *Gift of Society.*

Omaha, Nebraska, Department of Accounts and Finances. Report 1910-11, 1912-14. Gift of Superintendent of Accounts and Finances.

Organizing and Conducting Safety Work in Mines. U. S. Bureau of Mines. Technical Paper 103. *Washington, 1917.* Purchase.

Ottawa, Canada. Annual Departmental Reports for the Corporation, 1912. *Ottawa, 1912.* Gift of City Clerk.

Outlines of Industrial Chemistry; A Text-Book for Students. By Frank Hall Thorp, with assistance in revision from Warren K. Lewis. 3d ed. The Macmillan Co., *New York, 1916.* Cloth, 6 x 9 in., 665 pp., 137 illus. $3.75. Gift of the publisher.

The Panama Canal and Commerce. By Emory R. Johnson. D. Appleton & Co., *New York, 1916.* Cloth, 5 x 7 in., 295 pp., 8 illus., 7 maps. $2. Gift of the publisher.

Passaic, N. J. Financial Report, 1910, 1912-1916. Gift of City Clerk.

Pennsylvania. Commissioner of Health. Annual Report. 1914, Part I-II. *Harrisburg, 1916.* Purchase.

Pennsylvania. Commissioner of Labor and Industry. Annual Report (2d), 1915, Part II. *Harrisburg, 1916.* Purchase.

Pennsylvania Company. Annual Report (45th), 1917. *Pittsburgh, 1917.* Gift of Pennsylvania Co.

Pennsylvania State College. Annual Report, 1914-15. *Harrisburg, 1916.* Purchase.

A. S. M. E. Accessions

American Wool Preservers' Association. Report of Proceedings 13th Annual Meeting, 1917. Gift of Association.

Co-Partnership After the War. A Memorandum Submitted Feb., 1917, to the reconstruction committee appointed by H. M. Government.

Industrial Fatigue in Its Relation to Maximum Output. By Henry J. Spooner.

Investigation of the Municipal Light Plant. Report of. By C. W. Whiting, *Boston, 1917.*

Metropolitan Water and Sewerage Board. Annual Report (16th). *Boston, 1917.* Gift of Board.

National Board of Fire Underwriters. Address of R. M. Bissell, May 24, 1917.

National Machine Tool Builders' Association. Proceedings of Annual Convention, 1915-1916. Gift of Association.

New Orleans, La. Sewerage and Water Board. Report (34th semi-annual), 1916. Gift of New Orleans Sewerage and Water Board.

New York (City) Board of Water Supply. Information for bidders for vitrified brick pavement in the Kensico Aerator in the town of Mt. Pleasant, Westchester Co., N. Y. (Contract 184.) 1917.

——— ——— for surfacing with vitrified brick block the East Hill Drive at the Kensico Dam in the town of North Castle, Westchester Co., N. Y. (Contract 179.)

——— ——— for the completion of the superstructure over the drainage chamber at shaft 21 of the City Tunnel of the Catskill Aqueduct, in the Borough of Manhattan, 1917. (Contract 129.)

——— ——— for erecting, remodelling and removing buildings along the Catskill Aqueduct. (Contract 180.) Gift of the New York City Board of Water Supply.

Second Pan-American Scientific Congress. The Report of the Secretary General. *Washington, 1917.*

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by September 16 in order to appear in the October issue.

CHANGES OF POSITION

E. E. Arnold has left the employ of The New Departure Manufacturing Company, Bristol, Conn., and is now affiliated with the Iron City Products Company, Pittsburgh, Pa.

A. R. Dickinson, formerly connected with the Mill Management Department of Lockwood, Greene and Company, Atlanta, Ga., has become identified with the Winnsboro Mills, Winnsboro, S. C.

Dr. Barton Cruikshank has severed his connection with The Engineers' Company of New York, and is now designing engineer of the Maxim Munitions Corporation, Watertown, N. Y.

Edwin S. Boyer, until recently with Walter Kidde and Company, of New York City, has identified himself with the American Hard Rubber Company, of the same city.

Charles C. Hoke, formerly engineer with the Cia Minerales y Metales, Laredo, Tex., has accepted a position with the Compania Minera de Penoles, Mapimi, Tex.

W. C. Kerr is now affiliated with the Republic Railway and Light Company of New York City. He was formerly in the employ of the Philadelphia Rapid Transit Company, Philadelphia, Pa.

S. Howard Sweet has resigned from the Remington Arms-Union Metallic Cartridge Company, and has joined the Oil Engine Company, Bridgeport, Conn., in the capacity of chief engineer.

Raymond W. Muller, recently assistant maintenance engineer with the Bosch Magneto Company, New York City, has joined Walter Kidde and Company in the capacity of mechanical engineer.

George B. Malone has resigned from the Winchester Repeating Arms Company, New Haven, Conn., to take charge of the welding department of the Remington Arms Company, Bridgeport, Conn.

George W. Hawkins has identified himself with Anderson, Meyer and Company, Ltd., Shanghai, China. He was formerly Tucson manager of Chas. C. Moore and Company, San Francisco, Cal.

William E. Anderson, formerly designer with the Alberger Pump and Condenser Company, of New York City, is now associated with the A. S. Cameron Steam Pump Works, Phillipsburg, N. J.

W. A. J. London has severed his connection with the General Electric Company, West Lynn, Mass., to become engineer with the Steam Motors Company, Inc., Springfield, Mass.

W. H. Ripley, for several years associated with the Griscom-Russell Company as sales engineer and evaporator expert, has been appointed sales agent for the Nashua Machine Company, Nashua, N. H., to succeed the late W. E. Van Keuren.

C. C. Hinkley has severed his connection as chief engineer with the Chalmers Motor Car Company, Detroit, Mich., and is now president and general manager of the Hinkley Motors Corporation of the same city.

Henry M. Wood, formerly with The Lodge and Shipley Machine Tool Company, Cincinnati, Ohio, has assumed the duties of vice-president and general manager of The Malm and Wood Machine Company, Dayton, Ohio.

Charles L. Bruff has severed his connection with the United Gas Improvement Company, Philadelphia, Pa., and has taken up consulting engineering work, making a specialty of power-plant economy work.

George H. Sharpe has accepted the position of chief engineer with the Westcott and Mapes Company, New Haven, Conn. He was, until recently, mechanical engineer with the New York Central Railroad, Heat and Power Department.

A. H. Gill, formerly superintendent of the Perth Amboy plant of the American Smelting and Refining Company, Metuchen, N. J., has taken a position with the American Zinc and Chemical Company, Langeloth, Pa.

Charles J. Mancel has resigned from his position with F. W. Bird and Sons, East Walpole, Mass., and has assumed the duties of draftsman of the tool department of the Aeromarine Plane and Motor Company, Keyport, N. J.

G. C. Vennum, formerly assistant chief engineer of power plants, Union Electric Light and Power Company, St. Louis, Mo., is now associated with the Electric Bond and Share Company, New York City, in the capacity of mechanical engineer.

John F. Glenn, contracting engineer for the past seven years with the Wickes Boiler Company, Buffalo, N. Y., is now New England sales manager for the Edge Moor Iron Company, manufacturers of the Edge Moor water-tube boiler, Boston, Mass.

Edmund Barany, machine designer of the Singer Manufacturing Company, Elizabeth, N. J., has assumed the duties of assistant mechanical engineer of the Cleveland Twist Drill Company, Cleveland, Ohio.

John H. McNally until recently district manager of the Kokomo Foundry and Machinery Company, Philadelphia, Pa., has accepted a position as fuel engineer with Weston Dodson and Company, Inc., Bethlehem, Pa.

Frank Gentles, until recently in the engineering department of the Chester Shipbuilding Company, Ltd., Chester, Pa., has become affiliated with the engineering department of the Emergency Fleet Corporation, Washington, D. C.

Harold B. Bernard has resigned his position with the Oklahoma Petroleum and Gasoline Company, Tulsa, Okla., to accept the position of superintendent of the gasoline department of the Sinclair Oil and Gas Company, of the same city.

Charles W. Stephen, in charge of experimental work and testing of materials with the Bridgeport, Conn., division of the Crane Company, has severed his connections with the company and has accepted a position with the Pratt and Cady Company, Hartford, Conn.

Harry T. Anderson, formerly assistant in the tool-design department of the Simplex Auto Company, New Brunswick, N. J., has become identified with the Colt's Patent Firearms Manufacturing Company, Hartford, Conn.

Homer W. Goodier, formerly mechanical engineer with the Cayuga Cement Corporation, Portland Point, N. Y., has become connected with the Pierce-Arrow Motor Car Company, Buffalo, N. Y., in a similar capacity.

B. M. W. Hanson, vice-president and works manager of the Pratt and Whitney Company, Hartford, Conn., has resigned after nineteen years' service with the company and has accepted a similar position with the Colt's Patent Firearms Manufacturing Company, of the same city. Mr. Hanson has also resigned from the machine-gun board appointed by the U. S. Government, but he will continue to give the latter the benefit of his services, as far as his new duties will permit.

Frank H. Crockard, vice-president of the Tennessee Coal, Iron and Railroad Company since 1906, recently tendered his resignation, effective July 1, to accept the presidency of the Nova Scotia Steel and Coal Company, and will have charge of plans for a considerable extension of the company's operations. H. C. Ryding, who has served as Mr. Crockard's assistant for the past ten years, has succeeded to the position of vice-president of the Tennessee Coal, Iron and Railroad Company.

ANNOUNCEMENTS

A. P. Brush, of the Brush Engineering Association, has been selected by the Studebaker Corporation to serve as consulting engineer.

H. WADE HIBBARD, professor of mechanical engineering, University of Missouri, is now in Washington with the National Council of Defense.

L. L. WALKER, formerly district manager of the Good Roads Machinery Company, Philadelphia, Pa., is now sales engineer of the same company.

CRANSON D. GATES, who was associated with the Celluloid Company, Newark, N. J., in the capacity of chief draftsman, is now assistant works superintendent of the same concern.

EDWARD F. ENTWISLE, mechanical engineer at the Bethlehem Steel Company, Steelton, Pa., has been promoted to the general superintendency of the Donaghmore plant at Lebanon.

J. LEO MAYER, formerly connected with the Zanesville, O., works of the Mark Manufacturing Company, has become affiliated with the Indiana Harbor, Ind., office of the same company.

T. S. BAILEY, until recently with the Electric Boat Company at Groton, Conn., is now connected with the San Francisco, Cal., works of the same company.

ALVAH H. SABIN, consulting chemist of the National Lead Company, New York, and lecturer at New York University, was given the degree of Doctor of Science by Bowdoin College, June 21.

EARL N. MATTSON has been transferred to the Birmingham office of the American Cast Iron Pipe Company. He was until recently connected with the Chicago, Ill., office of the company.

GEORGE RAMSEY, senior member of the patent law firm of Ramsey and Parmelee, of Washington, D. C., is now in charge of the new office of the firm in New York.

WILLARD DOUD has accepted a commission as Lieutenant (Junior Grade) in the United States Naval Reserve Force, and has been assigned to active duty at the Naval Training Station, Great Lakes, Ill.

FRANK G. COX, until recently New England sales manager of the Edge Moor Iron Company, is now located in New York City as New York sales manager for the same company.

R. M. DYER, president of the Pacific Northwest Society of Engineers, addressed the June 28 meeting of The Engineers Club of Seattle, on Wooden-Ship Construction.

CLARENCE E. BIRKENBEUL, recently with The Holt Manufacturing Company, Stockton, Cal., as draftsman, has accepted a position with Meese and Gottfried of San Francisco, Cal.

JAMES OGG, with the American Cuban Estates Corporation, Santa Clara, Cuba, has become associated with the Honolulu Iron Works Company, Honolulu, Hawaii.

LOUIS E. KENFIELD, until recently mechanical engineer with R. Hoe and Company, New York, has entered the employ of The Locomobile Company of America, Bridgeport, Conn., in the capacity of chief tool designer.

HUGH P. FELL has assumed the duties of general superintendent of the Kings County Lighting Company, Brooklyn, N. Y. He was until recently associated with the Electric Bond and Share Company, New York.

WALTER H. VOLKMAR has severed his connections with the New England Westinghouse Company of Springfield, Mass., and is now with Baker, Sutton and Harrison, New York, industrial engineers and public accountants.

JAMES D. REIFSNYDER, formerly affiliated with the Stokes and Smith Company, Philadelphia, Pa., in the capacity of chief engineer, has assumed the duties of vice-president and manager of the Gefes Machine Company, Hoboken, N. J.

NEWMAN COMFORT has been transferred from the position of Ohio branch manager of the National Workmen's Compensation Service Bureau to that of Louisiana branch manager of the same bureau, with offices in New Orleans, La.

THOMAS CHESTER is now special representative, handling U. S. Navy business for the American Blower Company, with headquarters in New York. He was formerly associated with the Detroit, Mich., office of the same company.

B. B. MILNER, engineer of motive power of the New York Central at New York, will hereafter also perform the duties heretofore performed by the chief mechanical engineer, R. B. Kendig, deceased. The office of chief mechanical engineer has been abolished.

EDWARD J. KUNZE has resigned his position as professor of mechanical engineering at Oklahoma Agricultural and Mechanical College, to accept the commission of captain in the Quartermaster Officers' Reserve Corps, and has been ordered to Fort Sam Houston, Tex., for duty.

JOHN A. BRITTON, in addition to his present duties on the California State Council for Defense, will also serve on the national committee on gas and electric service, of which JOHN W. LIEB, of the New York Edison Company, is chairman.

AMOS WHITNEY, founder of the Pratt and Whitney Company, Hartford, Conn., was tendered a complimentary dinner by 40 members of the "Old Guards" at the Farmington, Conn., Country Club, June 20, in celebration of his eighty-fifth birthday.

B. F. RABER, associate professor of mechanical engineering and B. M. Woods, assistant professor of theoretical mechanics at the University of California, have returned from a governmental commission to Toronto, and are assisting in instituting a curriculum on military aeronautics at the State University.

THOMAS MORRIN, consulting mechanical engineer of San Francisco, Cal., announces that he has now associated with him, as partner, Albert A. Coddington, and that the business will hereafter be conducted under the firm name of Morrin and Coddington, consulting mechanical engineers.

THOMAS E. DURBAN has severed his connection with the Erie City Iron Works, Erie, Pa., as general manager, and has opened an office in the same city for the conduct of the affairs of the American Uniform Boiler Law Society, of whose Executive Council Mr. Durban is Chairman. This society was organized for the purpose of promulgating the A.S.M.E. Boiler Code.

HENRY M. LELAND, president of the Cadillac Motor Car Company, Detroit, Mich., and his son, Wilfred C. Leland, whose names have been connected so prominently with the perfection of gasoline engines, have announced their retirement from the automobile industry to devote their time and interests to the call of the nation. They are dedicating their services to the task of building up a powerful aeroplane fleet that will give the United States mastery of the air in the present war.

DAVID L. GALLUP, professor of gas engineering at Worcester Polytechnic Institute, Worcester, Mass., left for Indianapolis, July 1, to establish a research and consulting department for the Nordyke and Marmon Company, builders of the Marmon motor car. Professor Gallup will temporarily take the place of Howard Marmon who is going to France as an aircraft engineer of the aeroplane division of the United States Army.

APPOINTMENTS

A. R. MCARTHUR, resident engineer of the American Sheet and Tin Plate Company, at Gary, Ind., has been appointed a member of the School Board of that city.

D. MCCALL WHITE, formerly chief engineer of the Cadillac Motor Car Company, Detroit, Mich., has been appointed consulting engineer to the General Motors Company and will work closely with all of the General Motors divisions.

AUTHORS

FREDERIC G. COBURN has contributed an article on The Work of Management to the July number of *Industrial Management*.

H. F. STRATTON is the author of New Starters for Induction Motors, which appeared in the July 12 issue of *The Iron Trade Review*.

CHARLES M. HORTON has contributed an article on The Reason for Efficiency "Experting" to the July number of *Industrial Management*.

WALTER D. FULLER has contributed an article entitled Standardization in Office Work to the July issue of *Industrial Management*.

C. E. KNOEPPEL is the author of The Industrial Engineer and Preparation for War, which appeared in the July number of *Industrial Management*.

HALBERT P. GILLETTE has contributed an article entitled Logic for Engineers—Induction and Deduction, to the July 4 issue of *Engineering and Contracting*.

A. LEWIS JENKINS is the author of Effect of Countershaft Speed Ratio on Power and Torque, which appeared in the July 12 issue of the *American Machinist*.

THE NEW BOOKS

ALL books received by The Journal will be listed under this heading, generally accompanied by brief descriptive notes. Works of special importance to mechanical engineers will be commented on at length by members and others peculiarly qualified by reason of their experience and training.

Manufacture of Artillery Ammunition

Manufacture of Artillery Ammunition. By Members of the Editorial Staff of the *American Machinist:* L. P. Alford, Editor-in-Chief; F. H. Colvin, Ethan Viall, Robert Mawson, E. A. Suverkrop and John H. Van Deventer. McGraw-Hill Book Co., Inc., New York, 1916. Cloth, 6 x 9 in., xli+759 pp., 648 illustrations. $6 net.

This book is an excellent volume from a practical viewpoint of how the average shop equipment can be readily converted into a shop for the manufacture of munitions.

As a reference book for dimensions of the different types of munitions made for the different Governments, it is comprehensive and convenient.

As a general guide to one who is contemplating the manufacture of munitions with standard shop equipment, it would be of considerable value.

As a handbook for the student, it would prove not only convenient but valuable in giving him an idea of the general and detail requirements of munitions manufacture.

The authors deserve great credit for the thoroughness with which the subject has been covered. We all realize, however, that the progress which has been made in the manufacture of munitions since the book was published and the tendency to specialize in munitions manufacture, owing to the large quantities which the United States Government is now having made, would necessitate the use of the information in this book with care and caution.

Frederick A. Waldron.

Shop Expense Analysis and Control

Shop Expense Analysis and Control. By Nicholas Thiel Ficker, Consulting Industrial Engineer and Lecturer at N. Y. U. School of Commerce. The Engineering Magazine Company, New York, 1917. Cloth, 6 x 9 in., 236 pp., 20 illustrations. $3.

This book is not a general treatise on cost finding, but treats almost entirely of the problems that center around manufacturing expense and its allocation. The book consists of twelve chapters, the first eight of which were published originally in *The Engineering Magazine*. The titles and content of these chapters are as follows:

1 Establishment of the Unit of Time as a Basis of Distribution
2 Machine Expense and Material Expense
3 Classification and Interpretation of General Ledger Accounts Pertaining to Production
4 Distributing Manufacturing Expense to Production Centers and Segregating Power Expense
5 The Standardization of Rent Expense Distribution
6 Depreciation, Insurance, Taxes and Interest
7 The Machine Unit System
8 Current Variation Ratio for Adjusting Current Costs
9 Organization
10 Waste in Manufacturing
11 Graphic Determination of Costs
12 Standard Reports.

The object of the author, apparently, is to call special attention to the difficult problems involved in distributing expense burden in manufacturing plants. The treatment of the problem, however, is not very general, but describes the methods which the author believes are best for this purpose. These methods might or might not be applicable to every plant, depending on the industry and the size of the plant. The author's discussion of the problems of distributing expense burden, however, is clear and illuminating, and is based obviously on actual experience.

No theories are advocated that are especially new, but many of the author's methods and forms are both interesting and instructive, though all will not agree with some of his conclusions. The book is not as well balanced as one would wish. Too much space is devoted to Chapter 10, for instance, to detailed descriptions of wasteful methods, and the review of the principles of organization given in Chapter 9 covers ground that all who will read the book are thoroughly familiar with. On the other hand, little or nothing is said of methods other than those advocated by the author, which, as has been stated, may or may not be applicable to a given factory.

The book, however, will be interesting and helpful to managers, cost accountants and students of such matters, and should be in every library that is devoted to this line of work.

Dexter S. Kimball.

Laws of Physical Science. By Edwin F. Northrup. J. B. Lippincott Co., Philadelphia, 1917. Leather, 5 x 8 in., 210 pp. $2.

This book contains a collection of general propositions or laws of science grouped under the six headings Mechanics, Hydrostatics, Hydrodynamics and Capillarity, Sound, Heat and Physical Chemistry, Electricity and Magnetism, and Light, together with a combined author and subject index, arranged alphabetically.

The leading idea of the book is a most praiseworthy one, and the volume undoubtedly fills a gap in the reference literature of science. There are many publications giving more or less complete collections of tables of constants, formulæ, etc., and hitherto these have to some extent made up for the absence of a dictionary of physical laws, but the advantages of a book dealing entirely and systematically with these laws, which thus provides the authorities a historical and logical foundations for these tables, are obvious.

The typographical arrangement of the book is somewhat poor, and the use of italics in formulæ and for reference letters would be a decided improvement. For example, on page 37, to point out only one place, the roman letter "*l*" and the numeral "1" are indistinguishable.

Much remains to be done, however, before the book can really be considered "a very epitome of the world's heritage of the fundamentals of its knowledge and wisdom," as stated in the preface. Thus, looking over the index, we find no mention of the names of Arrhenius, Bunsen, Becquerel, Lavoisier, Quincke, Lehmann, Roentgen, Sir Oliver Lodge, and others; nor are there any references to Hertzian waves, X-rays, N-rays, cathode rays and dissociation. The development and present

status of the periodic law deserves more comprehensive treatment than the perfunctory reference to Mendeléeff on page 97. However, a good beginning has been made in a most useful undertaking and it is to be hoped that in the second edition the author will have due regard to possible improvements, some of which have been referred to here.

Paint Researches and Their Practical Application. By Henry A. Gardner. Washington, D. C. (privately printed), 1917. Cloth, 6 x 9 in., [illegible] pp., 156 figs. $5.

In this volume the author summarizes the investigations which he conducted at the Institute of Industrial Research for the Educational Bureau of the Paint Manufacturers' Association of the United States. Chapters are included on the following subjects: The Growth of the Prepared Paint Industry and Its Relation to the Work of the Painter; The White Pigment Industry; Physical Characteristics of Pigments and Paints; Tests of Lithopone; Washington Paint Oil Tests; Paint Protection for Portland-Cement Surfaces; Paints to Prevent Electrolysis in Concrete Structures; Paints for Metal; Marine Paints; Arlington Paint Tests; Observations on Painted Lumber; Impregnated Panel Tests; Fire Retardent Paints for Shingles and Other Wooden Structures; The Composition of Paint Vapors; The Toxic and Antiseptic Properties of Paints; The Light-Reflecting Values of White and Colored Paints; Formation and Inhibition of Mildew in Paints; Fungi on Painted Surfaces; Changes Occurring in Oils and Paste Paints, Due to Autohydrolysis of the Glycerides; The Effect of Pigments Upon the Constants of Linseed Oil; Storage Changes in Vegetable and Animal Oils; Paint Driers and Their Application; Miscellaneous Oil Investigations; The Application of Paints and Finishes to Wood.

American Hydroelectric Practice: A Compilation of Useful Data and Information on the Design, Construction and Operation of Hydroelectric Systems from the Penstocks to Distribution Lines. By William T. Taylor and Daniel H. Braymer. McGraw-Hill Book Co., Inc., New York, 1917. Cloth, 6 x 9 in., 439 pp., 258 figs. $5.

This is not a textbook on the fundamentals underlying the design and construction of the parts of a hydroelectric system, but a compilation of the practical and essential features of design, construction and operation as used in many plants, interpreted and arranged for use by designers and engineers. Contents: General Survey of Water-Power Engineering; Low, Medium and High Head Developments; Layout and Selection of Plant Equipment; Transmission Line Construction and Operation; Plant Line and Substation Costs; System Operation and Economics; Special Plant and Line Problems; Data, Reference Tables and System Diagrams.

War-ships. By Edward L. Attwood, M. Inst. N. A., Member of the Royal Corps of Naval Constructors, etc. Longmans, Green & Co., London and New York, 1917. Sixth edition. Cloth, 6 x 9 in., 338 pp., 209 illustrations. $4 net.

This textbook on the construction, protection, stability, turning, etc., of war vessels, while prepared primarily for the use of naval officers taking the course in naval architecture at the Royal Naval College, Greenwich, and amplified in certain particulars to meet their special requirements, is, nevertheless, believed by the author to be well adapted to serve as an introduction to the subject for students generally. The present edition, it is stated, has been modified in many places to take account of the rapid change of practice in recent years.

Handbook of Chemistry and Physics: A Ready-Reference Pocket Book of Chemical and Physical Data. Fifth Edition. The Chemical Rubber Co., Cleveland, O., 1917. Cloth, 4 x $6\frac{3}{4}$ in., 414 pp. $2.

In the present edition of this compact, easily portable and fairly comprehensive reference work, the text, it is stated, has been carefully revised and brought down to date and a large number of new tables have been added.

Export Trade Directory 1917-1918. Compiled by B. Olney Hough. Johnston Export Publishing Co., New York, 1917. Cloth, 6 x 9 in., 537 pp., 1 map. $5.

Contents: Export Merchants in the United States; Manufacturers' Export Agents, Managers of Export Departments and Export Brokers; Leading Bankers Engaged in Foreign Exchange Business; Foreign Exchange Brokers; Marine Insurance Companies in New York City; Foreign Freight Forwarders; Some Export Trucking Companies in New York City; Steamship Services to Foreign Ports; How to Ship to Foreign Markets; Consuls of Foreign Countries in the United States; United States Consular and Commercial Representatives in Foreign Countries; Associations for the Promotion of Export Trade.

Workmen's Compensation Law: Personal Injury by Accident Arising Out of and in the Course of the Employment. By P. Tecumseh Sherman. N. Y., Workmen's Compensation Publicity Bureau, New York, 1916. Paper, 6 x 9 in., 67 pp. $2.

This is a compilation of the decisions construing the British law on the subject, with abbreviated summaries of the relevant portions of the French and German laws. These precedents will be useful, the author believes, in defining the meaning of "accidents due to risk of work" as used in the American statutes.

Gas Chemists' Handbook. Compiled by Technical Committee, Sub-Committee on Chemical Tests, 1916, of the American Gas Institute, C. C. Tutweiler, Chairman, A. F. Kunberger, Editor, New York, American Gas Institute. Cloth, 6 x 9 in., 354 pp., 67 illustrations. $3.50.

The present handbook, a revision of the one compiled in 1914, presents methods for sampling and testing the material used in gas manufacture. Contents: Raw Materials; Products of Gas Manufacture; Impurities in Gas; Tar Products; Miscellaneous and Tables.

United States Artillery Ammunition: 3 to 6 in. Shrapnel Shells, 3 to 6 in. High Explosive Shells and Their Cartridge Cases. By Ethan Viall. McGraw-Hill Book Co., Inc., New York, 1917. Cloth, 9 x 12 in., 98 pp., 171 figs. $2.

This work is intended to give shop men, engineers and manufacturers an accurate knowledge of the sizes, tools, shop work and gages for the more commonly used United States shells and cartridge cases. The descriptions are in minute detail and accompanied by numerous dimensioned drawings.

Office Organization and Management. By Carl C. Parsons. La Salle Extension University, Chicago, 1917. Leather, 6 x 8 in., 313 pp., 59 figs. $2.50.

A work treating of organization, management, layout, equipment, methods, systems, records, forms, employees, etc., and based on observation of the methods used in the offices of various large companies.

Industrial Preparedness. By C. E. Knoeppel. The Engineering Magazine Co., New York, 1916. Cloth, 5 x $7\frac{1}{2}$ in., 145 pp. $1.

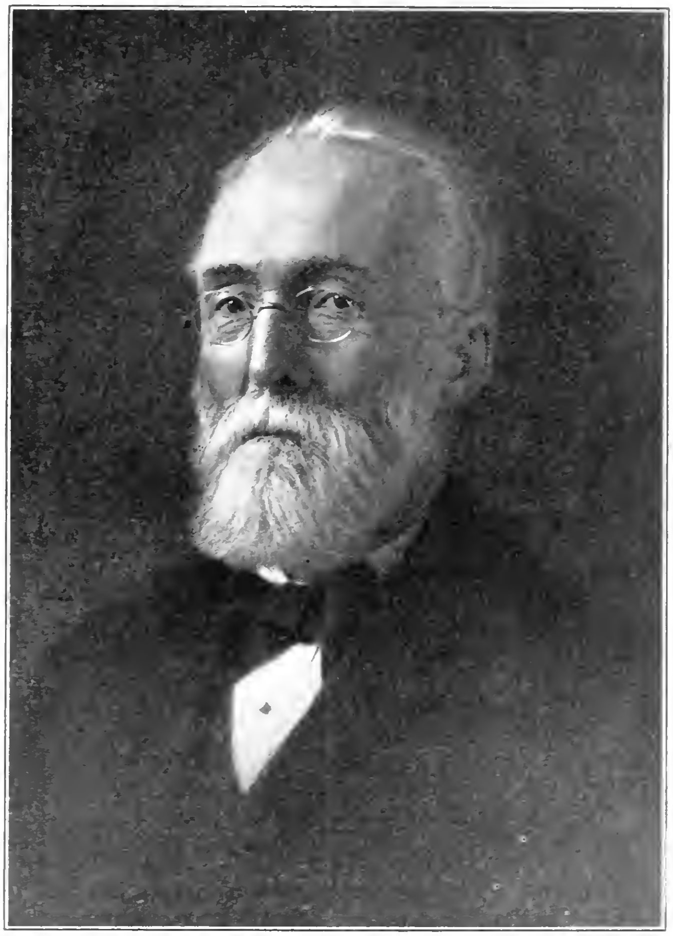
A study of Germany's military and industrial preparedness intended, the author states, to point the way to national greatness through the right kind of social, industrial and military preparedness.

AN ACCOUNT OF THE ENGINEERING WORK OF E. D. LEAVITT

By F. W. DEAN, BOSTON, MASS.

Member of the Society

A brief account of the life of the late E. D. Leavitt, Past-President, Am.Soc.M.E., was published in THE JOURNAL for April, 1916. In view of the interesting character of Mr. Leavitt's work, however, and of the influence which it had upon good design, particularly in relation to water works and mining machinery, it was desired to place on record a more complete statement of his life and work with illustrations of some of his most characteristic designs. Accordingly, a paper was prepared by Mr. F. W. Dean, who was closely associated with Mr. Leavitt and is intimately acquainted with his accomplishments. This paper is to be presented at the Annual Meeting and is here published in abstracted form with a selection of a few of the engravings.



THE LATE ERASMUS DARWIN LEAVITT, PAST-PRESIDENT AND HONORARY MEMBER OF THE SOCIETY, AN ACCOUNT OF WHOSE STRIKING WORK IN THE DESIGN OF LARGE STEAM ENGINES AND OTHER MACHINERY WILL BE GIVEN BY MR. F. W. DEAN AT THE FORTH-COMING ANNUAL MEETING

E. D. LEAVITT received his education in the public schools in Lowell, Mass., learned the machinist's trade in the Lowell Machine Shop, was assistant foreman at Harrison Loring's works at South Boston, was chief draftsman at the works of Thurston, Gardner & Co., at Providence, entered the Navy in 1861, and resigned therefrom in 1867. At this time he began the office practice of mechanical engineering, and on account of the times and his ability he achieved great success; not, however, without some discouragements.

I have understood that his first steam engine was designed for Crozer's cotton mill, in Chester, Pa., and built by I. P. Morris & Co., Philadelphia. This was a simple horizontal engine with a steam chest as long and wide as the cylinder. The chest contained a very large main valve worked by an eccentric and having a cut-off valve on its back at each end worked by a cam. The steam exhausted into the main valve which was hollow, and from this passed out through a special exhaust port. The main valve, being in a chest of live steam and having exhaust steam within, formed a condenser to some extent, and to persons who knew of Mr. Leavitt's great efforts in general to secure economy this was a subject of comment. Later he used the same design for the Brooklyn Bridge engines and for those of the El Callao Mining Co. of Venezuela. He appeared to be attached to this design and spoke of it as his cheap engine, but never mentioned its obvious defect.

Mr. Leavitt was firmly of the opinion that the best valve for a steam engine was the gridiron and he always used it except in the few cases mentioned above. Mr. Leavitt claimed that the gridiron valve was the only one that would remain tight indefinitely. The reason for this was that it has a great deal of wearing surface and no tendency to cock over and press more on one edge than the other, and that when operated by cams has a constant travel, except, of course, the cut-off valves as early cut-offs.

Mr. Leavitt used cams because they enabled him to secure exact and unchangeable motion to the valves.

The automatic cut-off feature was obtained by placing a cam on a hollow piece of shaft or sleeve through which the camshaft passed, and by suitable connection with the governor the cut-off cam could be advanced or retarded. This was accomplished by having a spiral slot cut in the camshaft and a straight one in the sleeve, a key made to fit both and moved by a sliding collar, which in turn was moved by the governor.

It is obvious that the governor moved the valve and therefore had to be large and powerful. For good governing this was not satisfactory, except for pumping engines, which ran slowly, and finally the governing apparatus was changed to that having a small high-speed governor whose function was to operate a balanced piston valve which admitted and exhausted water or oil under pressure to and from a hydraulic plunger and this moved the cut-off collar. Thus the governor had no

For presentation at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 4 to 7, 1917. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

resistance to overcome except friction, and could be made as sensitive as desired. After the first trial of this governor it was always used.

Mr. Leavitt's fame began with the installation of the Lynn, Mass., pumping engine, built by I. P. Morris & Co., which made an advance in economy over anything which preceded it. Its economical performance was based upon coal consumed, and upon its trial in December 1873 it gave a duty of 103,923,215 ft-lb. per 100 lb. of picked Lackawanna anthracite coal, based upon water discharged over a weir. While the feedwater was weighed and indicator diagrams taken, no evaporative rate for the boilers nor rate of steam consumption for the engine was given in the report.

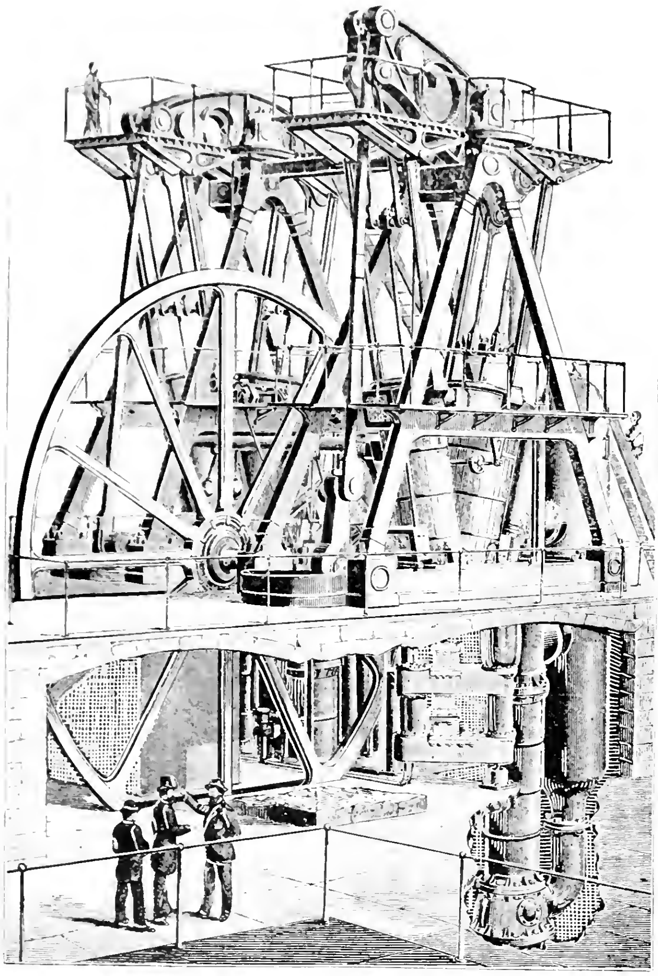


Fig. 1 The Lawrence Pumping Engine

The Lynn engine was soon followed by the Lawrence engines, also built by I. P. Morris & Co., which were tested for duty based upon 100 lb. of coal consumed and water discharged as determined by weir measurement. The test was made on May 2 to 6, 1876, and the duty was 96,186,979 ft-lb. per 100 lb. of Cumberland coal. The boilers were of an excellent design of the locomotive type and ought to have given a very high evaporation if properly fired. They only evaporated 8.27 lb. of water and 8.69 lb. on different tests per pound of coal from feed at 100 deg. fahr. and pressure at 89 lb. This was attributed to poor coal, but must have been due to poor firing. In those days calorimeter tests of coal and analyses of escaping gases were seldom made. Here again, while feedwater was weighed and indicator diagrams taken, the steam rate of the engine was not worked out.

Fortunately Park Benjamin's Scientific Expert Office tested one of the Lawrence engines in 1879 after the engine was over three years old. The principal data and results were as follows:

Date	July, 1879
Duration of test, hr	15.1
Kind of coal used	Cumberland bituminous
Diameter of high-pressure cylinder, in	18
Diameter of low pressure cylinder, in	38
Diameter of plunger, in	18.5
Stroke of steam pistons and plunger, ft	8
Diameter of flywheel, ft	30
Clearance of high pressure cylinder, per cent: top, 2.56; bottom,	2.31
Clearance of low-pressure cylinder, per cent: top, 1.54; bottom,	1.82
Steam pressure above atmosphere, lb	89.5
Vacuum, in	27.4
Revolutions per minute, average	13.62
Discharge of pump in 24 hr. by plunger displacement, gal.	4,461,272
Duty per 100 lb. of coal consumed, based upon plunger displacement, ft-lb	111,548,925
Temperature of feedwater, deg. fahr	119
Temperature of escaping gases, deg. fahr	358
Coal consumption per sq. ft. of grate per hr., lb	8.38
Actual evaporation per pound of coal, lb	10.13
Equivalent evaporation from and at 212 deg., lb	11.49
Equivalent evaporation per pound of combustible from and at 212 deg., lb	12.24
Coal used per indicated horsepower per hr., lb	1.63
Feedwater used per hr., lb	2437
Feedwater used per indicated horsepower per hr., lb	16.48
Condensation in high-pressure cylinder jacket per hr., lb	118
Condensation in low-pressure cylinder jacket per hr., lb	160

In this table we have means of judging of the economical performance of both boiler and engine. The former was among the best and the latter was probably as good as that of any steam engine up to that time. There appears to have been no determination made of the moisture in the coal or in the steam.

The perspective drawing given in Fig. 1 and taken from the Park Benjamin report gives a good idea of the Lawrence engines, and serves the same purpose for the Lynn engine, there being one engine in the latter case.

THE BOSTON SEWAGE ENGINES

When the City of Boston undertook to dispose of its sewage by discharging it into the ocean south of the harbor limits, it became necessary to raise it about 40 ft. near the north shore of Dorchester Bay. Mr. Leavitt designed two vertical compound flywheel engines for this purpose, which are shown in Fig. 2. These were built by the Quintard Iron Works, New York, and were vertical inverted compound flywheel beam engines of the following general dimensions:

Diameter of high-pressure cylinder, in	25¼
Diameter of low-pressure cylinder, in	52
Diameter of each of the two plungers, ft	4
Stroke of each piston and plunger, ft	9
Number of plungers	2
Number of revolutions per minute, nominal	10¾
Capacity in 24 hr., nominal, gal	25,000,000

The cylinders were steam-jacketed and there were tubular reheaters between the high- and low-pressure cylinders, one being between the upper ends of the cylinders and the other between the lower ends.

In 1885 one of the engines and its twin-furnace locomotive-type boiler were tested by Dexter Brackett with the following results:

Dates of trials, 1885	Mar. 24-25	May 1-2
Duration	24h. 43m.	24h. 3½m.
Revolutions per minute, average	13.17	13.42
Total lift, ft	37.80	42.43

Total dry coal consumed, lb.	8,307	9,478
Duty per 100 lb. dry coal, ft-lb.	125,450,000	122,400,000
Mean boiler pressure, lb. per sq. in.	99.4	98.6
Mean vacuum in condenser, in.	28.1	28.0
Total plunger displacement, gal.	33,038,000	32,778,000
Total discharge by weir, gal.	30,224,000	31,256,000
Average slip, per cent	8.5	4.6
Approximate indicated horsepower	251.5	290.2
Plunger horsepower, no allowance for slip	212.9	243.5
Mechanical efficiency, per cent	84.66	83.90
Approximate coal used per i.hp. per hour, lb.	1.33	1.35
Approximate steam used per i.hp. per hour, lb.	13.89	14.09

In 1889 he designed a larger triple-expansion engine for the same place.

THE LOUISVILLE PUMPING ENGINE

The next pumping engine of Mr. Leavitt's design to attract attention was the Louisville engine, built by the I. P. Morris Co., and it was the first to be thoroughly tested. The test was conducted by Dexter Brackett and F. W. Dean and lasted 144 hr. 10 min. without stopping.

The engine was arranged similar to the Boston sewage engines, but had the flywheel shaft near the floor level and at one end of the bedplate instead of being elevated and between or just below the lower ends of the cylinders. The reheaters were of the same type.

The following are the general results of the test:

Diameter of high-pressure cylinder (hot), in.	22.21
Diameter of low-pressure cylinder (hot), in.	54.13
Diameter of high-pressure piston rod, in.	5.50
Diameter of low-pressure piston rod, in.	6.00
Stroke of each piston, ft.	10
Mean clearance volume of high-pressure cylinder, per cent.	1.585
Mean clearance volume of low-pressure cylinder, per cent.	1.530
Diameter of each differential plunger, in.	34 & 24 1/16
Stroke of each differential plunger, ft.	7
Diameter of flywheel, ft.	36
Duration of trial	144h. 10m.
Revolutions per minute, average	18.574
Average steam pressure at the engine, lb. per sq. in.	137
Back pressure on low-pressure piston, lb. per sq. in.	0.95
Total head, ft.	193.35
Total dry steam used by engine in cylinders and jackets, lb.	1,127,533
Dry steam used per i.hp. per hour including jacket steam, lb.	12.156
Horsepower of high-pressure cylinder	279.00
Horsepower of low-pressure cylinder	364.40
Horsepower of both cylinders	643.40
Horsepower of plungers	599.10
Mechanical efficiency of engine, per cent.	93.12
Duty per 1000 lb. of dry steam by plunger work, ft-lb.	150,838,000
Duty per 1,000,000 B.t.u. by plunger work, ft-lb.	151,672,000
Avg. capacity of engine in 24 hr. by weir, U. S. gal.	16,489,420
Avg. capacity of engine in 24 hr. by plungers, U. S. gal.	17,681,350
Average slip of plungers, per cent	6.74

THE WASHINGTON MILLS ENGINES

These are the only Leavitt power engines that have ever been thoroughly tested as far as I know. They were put in under a guarantee and tested by John T. Henthorn and E. D. Leavitt, Mr. Leavitt being represented by A. M. Mattice. They were built by the Dickson Mfg. Co., Scranton, Pa., and were a pair of 30-in. by 60-in. steam-jacketed horizontal non-condensing engines running at 60 r.p.m. and driving a 30-ft. wheel grooved for thirty $1\frac{3}{4}$-in. ropes. The test was made after the engines has been in operation about three years, and the general results obtained are as follows:

Duration of test (June 12-19, 1890)	One week, mill hours
Running time	61 hr. 41 min
Average steam pressure at engines, lb. per sq. in.	132.2
Average revolutions per minute	58.82
Average back pressure, lb. per sq. in.	7.98
Average indicated horsepower both engines	1199.2
Net moist steam used by engines (including jackets) per i.hp. per hour, lb.	23.16
Per cent of steam used by jackets	3.05

DETAILS OF ENGINE DESIGN

Cams. In the early Leavitt engines the cams were made with grooves in the side and the throws were inserted hardened steel. The high-pressure cut-off cam, although it appeared to be grooved, was not in fact. It consisted of two cams, one recessed and overhanging the other. The opening cam was secured to the camshaft and the cut-off cam to the hollow shaft which was controlled by the governor. The rolls which were actuated by the cams were on pins overhung from rockers.

When the hoisting engine Superior was built, having cylinders 40 in. and 70 in. by 6 ft., grooved cams were used. The camshaft was located near the floor level, and as the engine was vertical and inverted, the valve rods were very long and heavy. It was intended to run the engine at 60 r.p.m., but the valve gear would not operate satisfactorily, I have understood, at over 35 r.p.m. The noise was so great at higher speeds that conversation could not be carried on nearby without shouting at close range, and breakages of the cut-off cams and levers occurred. The outcome of the trouble was that a new valve gear was designed which was light and possessed small inertia stresses. In the case of the Superior the camshaft was raised to a level with the middle of the cylinders and was supported, together with the valve gear, by means of brackets attached to the valve-chest bonnets. The valve rockers for the lower valves extended downward, and for the upper valves upward, from the camshaft.

The outside cams had rolls on opposite sides rotating on pins in forked rockers so that there were no overhung pins. The pair of rockers of one cam were connected together by links, and the throws of the cams were so formed that both rolls always touched the cams. The Superior was started with the new valve gear in the latter part of 1883, and has been running ever since, from 20 hours to 24 hours per day, with the utmost satisfaction.

Fig. 3 shows the Superior with a new valve gear, while the paper by Mr. Leavitt in Vol. 2 of Transactions (facing p. 120) shows it with the original gear.

Cylinder Design. The Leavitt cylinders were always steam-jacketed and had the jacket cast on. Mr. Leavitt always feared leakage with cylinders having liners. The jacket was cast with an opening all round the center and this was covered with a copper ring with one corrugation. The ring was secured by two rows of tap bolts on each side. The division of the jacket wall in this way was the result of some serious disasters. The jackets of the Lynn and Lawrence pumping engines were cast without the division and straight, with the result that one or more of them cracked and had to be replaced. A cylinder of a steam stamp at the Calumet and Hecla Mine made without provision for jacket expansion broke and went through the roof of the building.

The steam chests of the cylinders were always cast on, and sometimes the crank-end head was cast in, and sometimes it was separate. Fig. 4 shows a typical cylinder. This design shows the inner wall serrated in order to provide more surface for contact with steam and thus render jacket action more active. This was a feature not always used, and was borrowed from the practice of a well-known Belgian engineer.

Valves and Valve Seats. The valves were rectangular plates with one end formed to receive T-ended valve stems. The ports were slotted. The seats were secured to the cylinder by means of studs, and the surfaces of contact between the cylinder and seat were scraped to continuous contact. The bridges between the ports of the seats were each provided with

an oil groove. There were two yokes secured to the seats for preventing the valves from leaving the seats too far. In vertical cylinders the seats were somewhat inclined so that the valves would tend to rest against them.

In order to fill up all unoccupied spaces blocks were screwed in or cast on to reduce the clearance volume.

In designs made since about 1888, the clearance volume was still further reduced by casting V shaped forms on the cylinder ports under the bridges of the valve seats. This added to the condensing surface of the clearance, and in fact all other devices for diminishing clearance did this also, and I have

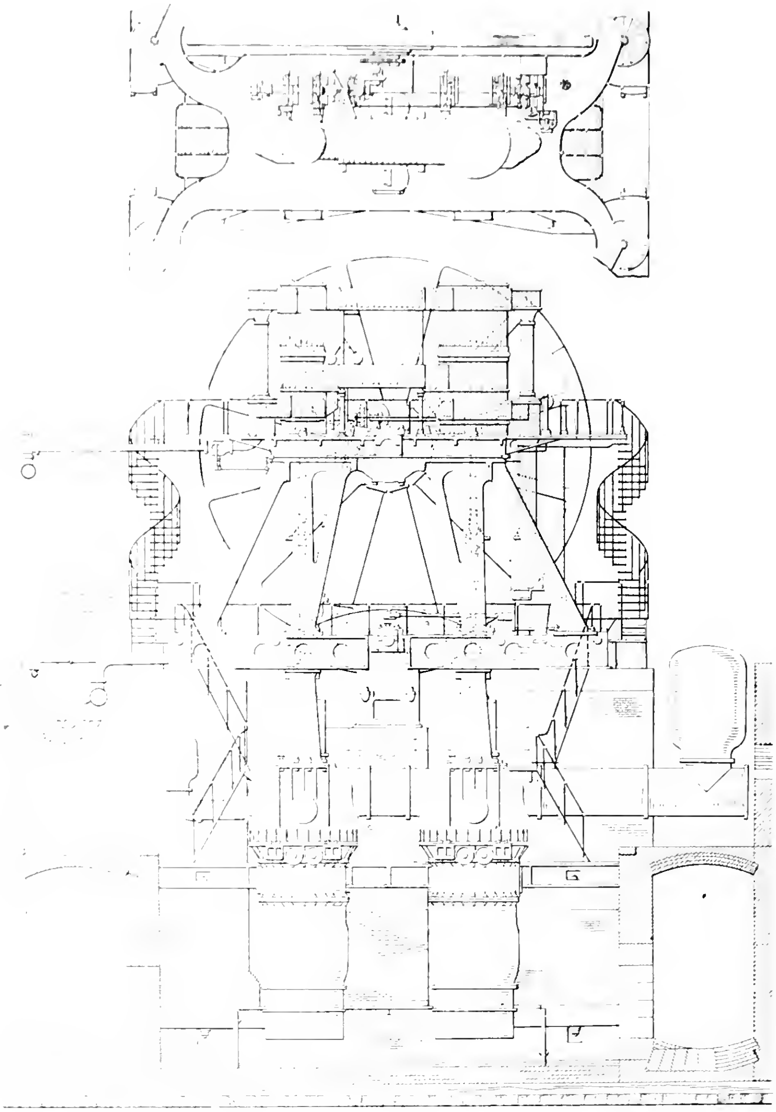

FIG. 2 BOSTON SEWAGE PUMPING ENGINE

no doubt that whatever may have been gained by reducing clearance was lost by the increase in surface. All Leavitt engines gave an indicator diagram with a long drop in the compression line. The compression would go on for a time and then there would be a collapse which would not be recovered. I think that this was caused by condensation in the clearance which in turn was caused by the great amount of surface in the valve-seat ports and other parts.

There was always means of operating the valves by hand, and this involved a handwheel something like the steering wheel of a steamboat except that it was of steel. There were two clutches moved by a lever, one of which engaged the cam-shaft with a driving shaft and the other engaged it with the handwheel. One of course was engaged when the other was disengaged. The operation of starting consisted chiefly in placing the valves in the proper position, opening the throttle and throwing the clutches at the proper time. The skill required to do this was easily acquired.

THE LEAVITT BEAM ENGINE

Mr. Leavitt was very fond of the inverted beam engine for the reasons that it made a very low engine and was long and stable in the direction of motion of the parts, and cheapened the building by making it lower. The beam was generally made of air-furnace or gun iron, but later of steel castings. The weights of the beams and reciprocating parts were very great and they all moved in the same plane, but no trouble came from this in practice.

The usual place for crossheads was above the beam, but they have been placed below, and in this case the links from the crossheads extended upward to the beam pins. The beams were generally made in two "flitches" (to use Mr. Leavitt's word), but sometimes in a single piece. The connecting-rod

pin sometimes was overhung from the beam, but oftener was between the flitches.

In compound engines the high-pressure cylinder was above one end of the beam and the low-pressure cylinder above the other, but in 1886 Mr. Leavitt began the design of triple-expansion engines, which he arranged by having the high and intermediate cylinders above one end of the beam and the low-pressure cylinder above the other. The high and intermediate pistons had coincident motions. The steam pressure used for compound engines was 135 lb. and for triple-expansion engines 185 lb.

Reheaters were used in each case, and it may here be remarked that Mr. Leavitt had great difficulty in making the reheater tubes tight in the tube plates.

In some of the later triple-expansion or three-cylinder compound engines three beams were used and each piston was connected to one end of each beam, and there were three connecting rods and three cranks 120 deg. apart. These were certainly beautiful pieces of mechanism and operated to perfection. The first such engine was the Riedler pumping engine of the Boston Water Works, built in 1894 and shown in Figs. 5 and 6.

The engine at the Bethlehem Steel Co., designed by Mr. Leavitt for pumping water for the forging press and built by the I. P. Morris Co., is another example of this arrangement, and there are three of them driving electric generators at the stamp mill of the Calumet and Hecla Mining Company, as well as several hoisting engines of this type. In the stamp-mill engines, although gridiron valves were used, they were not operated by cams. They were opened by eccentric rods and were provided with latches and dashpots as in Corliss gears. This feature of the valve gear was caused by the engines having been built for a reversing hoisting gear, and the valves could be better controlled by a reversing link when so made than if reciprocating cams were used as on the engines Minong and Siscowit.

HOISTING MACHINERY

For many years the method of hoisting at both the Calumet and the Hecla mines was by means of constant-running engines, which also drove air compressors. The hoisting drum was on a shaft to which it was not secured except by means of a clutch. There was also a brake to prevent the drum from moving and holding it fast whether the engine was running or not. Both the clutch and brake were operated by means of hydraulic pressure from an accumulator, and the levers for controlling them were interlocked so that the clutch and brake could not be thrown on simultaneously. The clutch cylinder was secured to an arm of the flywheel and the water was introduced through the shaft which was bored for the purpose. The brake was secured to a post which was firmly bolted to the foundation. The brakes and clutches were of the strap type and worked on wood. There was an indicator to show the position of the skip in the shaft, and an anti-overwinding device, which I believe was never used. The drum centers were in halves, and were lined continuously with babbitt metal. The rope faces were sometimes straight and sometimes conical, and the arms were of wrought rods.

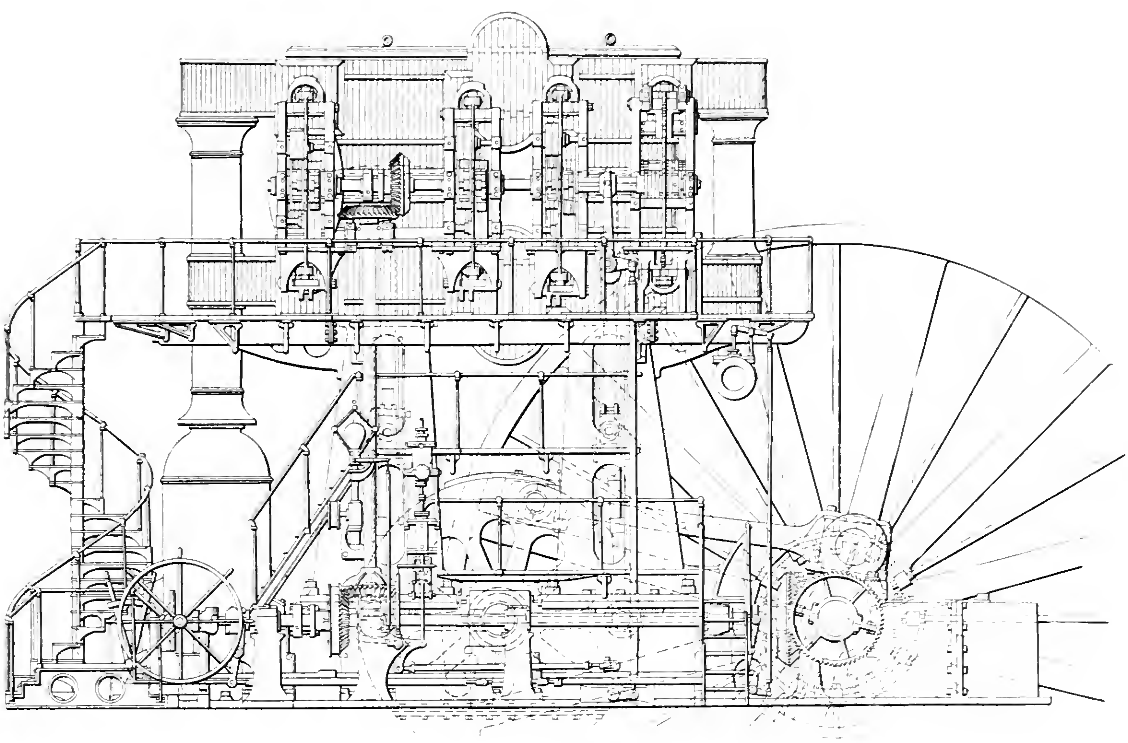

Fig. 3 The "Superior" Engine

When Mr. B. S. Whiting entered the employ of the Calumet and Hecla Mining Company the Whiting system of hoisting was introduced. This was first used at the Red Jacket shaft, and consisted of two cages, one descending and the other ascending, with a rope from the bottom of one to the bottom of the other, and thus being balanced. The engine drove a pair of narrow-faced drums with two wraps over both drums. The drum shafts were coupled together like the wheels of a locomotive and the engines were reversing.

The introduction of reversing engines brought new problems in engine design and the first engines were the Minong and Siscowit. These were vertical, triple-expansion condensing beam engines using 185 lb. steam pressure. They had cam-operated gridiron valves with automatic cut-offs on the high-pressure cylinders. The cams were reciprocating. The

Walschaert's gear was used, the lap and lead were derived from the beam [illegible], and the reversal was affected by hydraulic mechanism.

Afterward there were several other installations of the Whiting system with other types of engine.

COMMERCIAL ENGINES

Mr. Leavitt recommended quite a number of commercial engines for hoisting, pumping and for driving air compressors, but they were usually for spare units or for temporary purposes. For instance, the Superior originally drove hoisting drums on one side and air compressors on the other. On the air compressor side and beyond the compressors there was a spare Corliss engine which could be coupled on to drive the compressors if the Superior had to be stopped. At the other side there was a 40-in. by 60-in. horizontal condensing Leavitt engine for driving the hoisting drums in an emergency. At the Hecla mine there was an exactly similar arrangement with the Leavitt vertical compound condensing beam engine Frontenac in the middle driving in both directions, with a spare commercial Corliss engine at each end. Similarly there were various commercial engines in other hoisting houses, and not

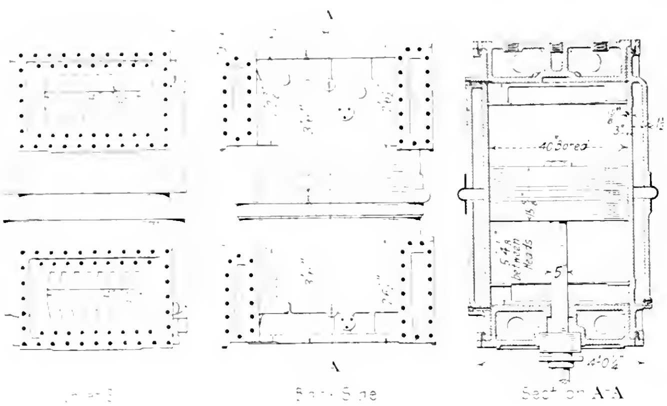

Fig. 4 Typical Engine Cylinder

always spare engines. In such cases the commercial part was the smallest.

AIR COMPRESSORS

A great many air compressors are needed at the Calumet and Hecla Mines, and up to a certain time commercial compressors were used. Soon after the installation of wet compressors at the St. Gothard Tunnel in Switzerland, Mr. Leavitt was impressed with the advantages of the type and designed a pair of 42-in. by 60-in. by 30-r.p.m. wet compressors. These were placed in the Hecla hoisting house and were similar to double-acting pumping engines, the plunger causing water to rise and fall in two vertical cylinders or chambers—one at each end. At the top of each of these chambers there was a valve deck having inlet and discharge air valves, and below there were spray nozzles for cooling the air. The spray water was pumped by a small attached pump. There was a separator in which the water settled, and the quality of the air was satisfactory. These compressors were successful, but later when similar ones were installed at the Calumet hoisting house to run at double the speed, as I understand, they were unsuccessful on account of that speed and were replaced by dry compressors.

PUMPING ENGINES

Something has already been said about Leavitt pumping engines, and it is well to state that the Lynn type of engine was used only at Lynn and Lawrence. When the first engines were designed for the Calumet and Hecla Mining Company they were inverted, and with the high-pressure cylinder inclined for the purpose of having the cylinders as near together as possible and thus reducing certain losses. Between the near ends of the cylinders there was a single valve which was both high-pressure exhaust and low-pressure inlet. At the distant ends there were two valves which moved simultaneously, one being the high-pressure exhaust and the other the low-pressure inlet, although the Lynn engine had only one valve between the distant ends of the cylinders. Later, when the Boston sewage, Fig. 2, and the Calumet Pond pumping engines were designed the cylinders were all vertical and reheaters were used.

The greatest requirement for water at the Calumet and Hecla mine is at the stamp mill, which is some six miles from the mine, on Torch Lake, which is an inlet from Lake Superior. The pumping engine Ontario and the large-capacity spare pumps Huron and Arcadian are there. The engine Michigan is the largest engine at the stamp mills, and has cylinders 18 in., 27¾ in. and 48 in. by 90 in. and two plungers with the suction ends 48 in. by 90 in. The number of revolutions per minute was intended to be 30 and the capacity 60,000,000 gal. in 24 hours. It runs usually at 28½ r.p.m. The head is about 40 ft. This engine uses steam of 185 lb. pressure. The Michigan was a bold design, as it is supported by wide, straddling cast-iron columns as shown by Fig. 7. This engine had pump cylinders which were oval at the valve level for accommodating the valves, and were of great size, being 9 ft. 10 in. wide the narrow way and 14 ft. 2 in. the other way. They were cast of gun iron.

The Lynn and Lawrence engines had each one plunger, this being of the Thames-Ditton type, being single-acting on the suction and double on the discharge, with a few large double-beat metal valves. This type of plunger was not used later, but instead of this the differential plunger was used. This plunger is of two diameters, the lower part having twice the cross-section of the upper. The lower section passed through the discharge valve deck and the upper section through the top of the pump. This plunger is single-acting on the suction and double on the discharge, and two were always used, one being under each end of the beam. The differential plunger was invented by Mr. Leavitt, but he soon found that he was anticipated in this.

The sewage engines designed for the City of Boston had each two plungers of a single diameter.

The largest Leavitt pumping engine, designed in 1889 and built by the I. P. Morris Co., was the last sewage engine for Boston, already referred to, the cylinders being 18½ in., 33 in., and 52¾ in. by 10 ft. stroke. The plungers, of which there are two, are 60 in. in diameter by 10 ft. stroke, and the rated capacity 75,000,000 gal. in 24 hours against a head of about 40 ft. The speed is 18 r.p.m.

The Cambridge engine, designed in 1895 and built by the De La Vergne Machine Co., New York, was a triple-expansion engine using 185 lb. pressure. The cylinders were 18½ in., 33 in., and 52¾ in. by 7 ft. 6 in. stroke, and the plungers (two differential) 19⅜ in. and 27¾ in. by 7 ft. 6 in. stroke. Its rated speed was 32 r.p.m., and this gave a piston and plunger speed of 480 ft. per min. and a capacity of 20,000,000 gal. in 24 hours. If the engine had run slower it would have been more satisfactory.

At about the time the Cambridge engine was designed Mr. Leavitt was commissioned with the design of a pair of engines for the city of New Bedford, Mass., which were built by the Dickson Mfg. Co. It was decided to make these engines compound and to use 185 lb. pressure, in order to compare their economy with that of the Cambridge engine using the same steam pressure and being triple. I do not know whether the comparison was ever made, but the station economy of the New Bedford engines is better than that at Cambridge. The steam cylinders of the New Bedford engines are 16⅜ in. and 36¼ in. by 7 ft. 6 in. stroke, and the pump plungers are 13.7 in. and 19⅜ in. by 7 ft. 6 in. stroke.

A feature of some Leavitt pumps is that under each suction valve there is a tube several inches long with a bell lower end, the object being to form a suction air chamber between the tubes. I am not aware that any benefit from this construction was identified. It was used on some Calumet and Hecla engines, and also on the Cambridge and New Bedford engines.

Mr. Leavitt was a great believer in steam jackets, and used boiler pressure for this purpose, even in low-pressure cylinders of engines using 185-lb. steam. It is known that these engines exhausted steam considerably superheated into the condensers, but I believe that Mr. Leavitt held that there was great benefit in drying the steam as much as possible before it left the cylinder.

The Leavitt pump valves were not as small as those used in commercial engines. They were usually faced with leather and had separate adjustments for the lift and tension of the spring. For sewage engines the valves were rectangular and hinged on one side, each covering an opening of 4 in. by 16¾ in. in the latest engine.

Mr. Leavitt became acquainted with Professor Riedler, of Berlin, and I believe acquired the right for a time to use the Riedler pump in the United States. The Riedler pumping engine for the city of Boston, already referred to (Figs. 5 and 6) was a triple-expansion three-cylinder, three-beam, three-connecting rod, three-crank and three-pump engine, and was the only one designed by Mr. Leavitt.

The pumps were inclined and double-acting, located at the rear of the engine and operated by connections to the beams. Each pump had a single suction and a single discharge valve at each end operated by mechanism.

The engine was built by the Quintard Iron Works, New York. As it was intended to surpass all previous efforts at economy, the results of a test made by some students of the Massachusetts Institute of Technology under the direction of Prof. Edward T. Miller are herewith given:

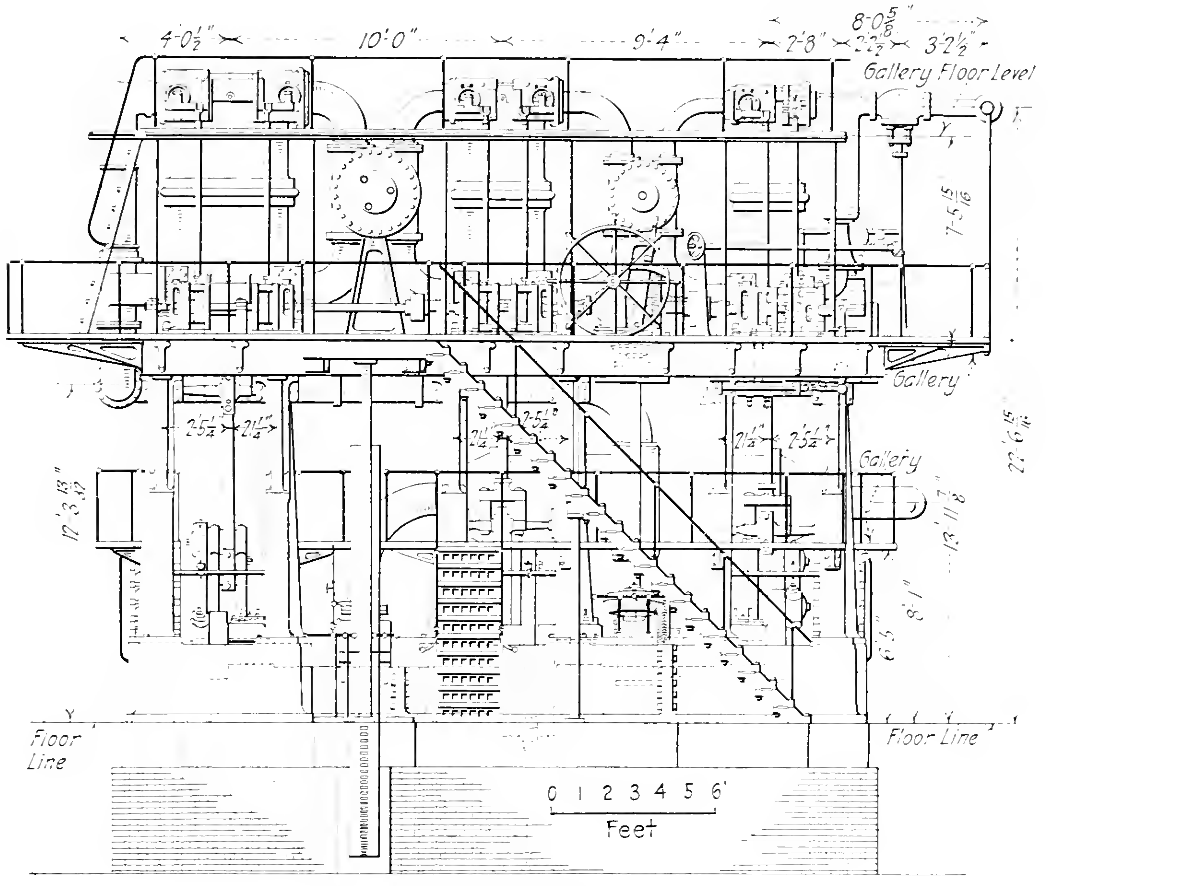

Fig. 5 Riedler Pumping Engine

Diameter of high-pressure cylinder, in.	13.7
Diameter of intermediate-pressure cylinder, in.	24.375
Diameter of low-pressure cylinder, in.	39
Stroke of each piston, in.	72
Diameter of each plunger, in.	17.5
Stroke of each plunger, in.	48
Rated capacity in 24 hours at 50 r.p.m., gal.	20,000,000
Type of condenser	surface
Steam pressure, lb. per sq. in.	185
Type of boiler	Belpaire locomotive
Duration of trial, hours	24
Average number of revolutions per minute	50.585
Average steam pressure at throttle, lb.	175.7
Average vacuum in condenser, in.	27.25
Average pressure in first receiver, lb.	46.5
Average pressure in second receiver, lb.	2.4
Average pressure in high and intermediate cylinder jackets, lb.	175.7
Average pressure in low-pressure cylinder jacket, lb.	99.6
Indicated horsepower of high-pressure cylinder	150.86

Indicated horsepower of intermediate cylinder	186.44
Indicated horsepower of low pressure cylinder	238.66
Total steam horsepower	575.66
Total pump horsepower ..	529.86
Mechanical efficiency, per cent	92.
Friction, per cent	8.
Water discharged in 24 hours by weir measurement, gal	24,016,000

Dry steam used per I.hp. per hour, engine only, lb	11.22
Coal used per I.hp. per hour, whole plant, lb	1.18
Duty per 100 lb. coal, ft lb	150,045,000
Duty per 1,000,000 B.t.u., ft lb...	115,470,000
Duty per 100 lb. combustible, ft lb	160,000,000

THE LEAVITT STAMP

The steam stamp devised by Mr. Leavitt for stamping rock containing native copper is a gigantic steam hammer about thirty-eight feet high above the foundation. See Fig. 8. When Mr. Leavitt began to study economy of steam for stamps he found great room for improvement, and then devised his well-known stamp. It has two pistons on the same rod, the upper one being considerably larger than the lower. Steam for the blow acts upon the top of the upper or larger piston and is admitted by a gridiron valve and exhausted by another to a condenser. Both valves are operated by cams. The space between the upper and lower pistons is constantly connected to the condenser. The space under the lower piston is occupied by live steam and serves to lift the stamp, and the steam thus used is churned into and out of a reservoir, and thence to and from the steam pipe. The lower piston enters a compression chamber at the bottom to limit the downward stroke, while the upward stroke is limited by a lower piston entering a dashpot.

As appears to have been the custom at the Lake Superior mines, the stamp anvil, which has been made of various weights, rested formerly on large maple spring timbers. In about 1900 these were omitted and the anvil placed directly on the foundation. By this means the output of the stamp was increased and the vibration of the surrounding territory diminished. There are 27 Leavitt stamps at the Calumet and Hecla stamp mills, each making 108 blows per minute.

The valve gear and condenser pump are driven from a shaft which serves a long line of stamps. Later, I understand, the exhausts of all of the stamps were taken to low-pressure turbines, with the result that some of the power engines were shut down, and considerable economy resulted.

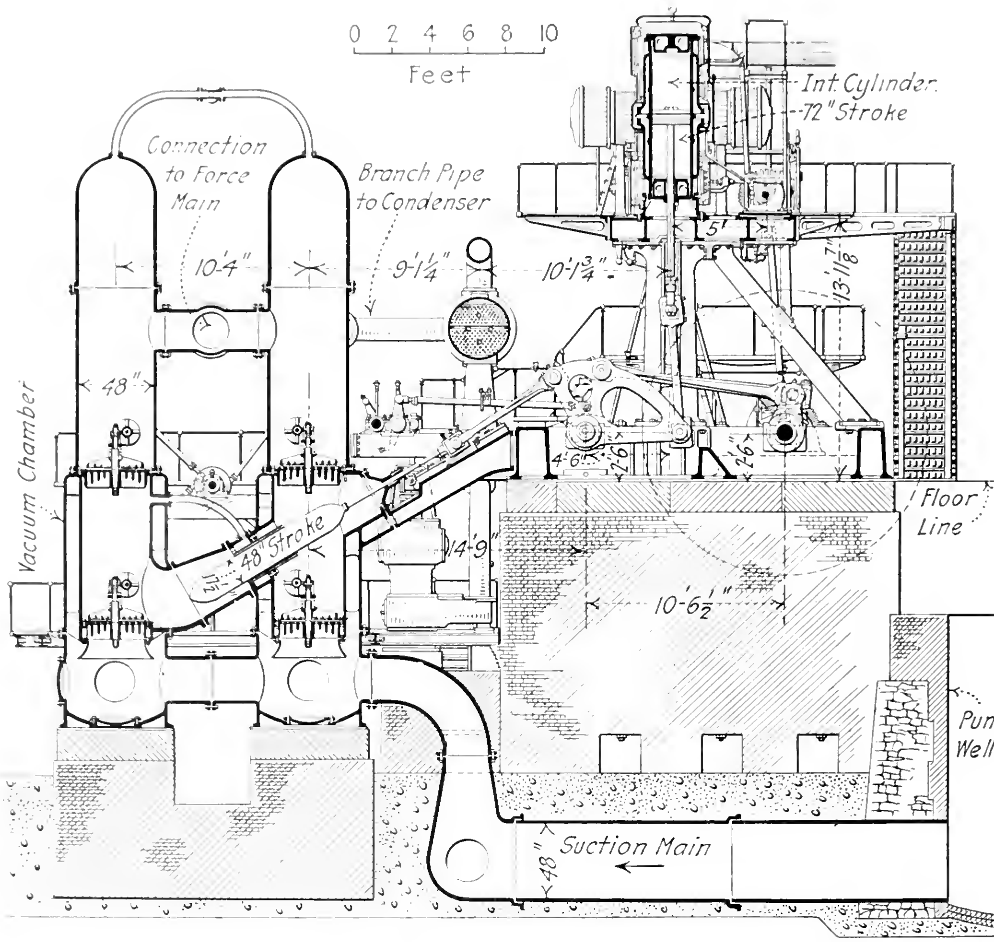

FIG. 6 RIEDLER PUMPING ENGINE

BOILER PRACTICE

Mr. Leavitt was a great advocate of the locomotive boiler and usually installed this type. I understand that before adopting it he designed some boilers for the Calumet and Hecla mine which were a sort of "elephant" boiler, and these were failures. After this the locomotive type was always used, and these were a great success. They had a firebox with a mid-water leg, thus forming two fireboxes. The mid-water leg extended forward from the firebox and formed two so-called flues to a single combustion chamber which ended at the tubeplate. The length of the flues was often 3 ft. 6 in. and the combustion chamber 4 ft. At the end of the grate there was a 20-in. firebrick wall, thus making the distance from the end of the grate to the tubeplate 9 ft. 2 in. In 1882, or thereabout, brick arches began to be used, as in locomotive practice.

Originally the boilers had a round top above the crown sheet,

but later, due to the writer's influence, the Belpaire form of firebox and method of staying was adopted. Up to about this time the joints in the barrel of the boiler were butted, both longitudinal and circumferential, but Mr. Leavitt was influenced to abandon the latter for lap joints. The longitudinal butt joint was, of course, preserved, and it is interesting to know that the prevailing form of butt joint used in this country, viz., that having a narrow outside and wide inside strap, was devised by Mr. Leavitt and Edward Kendall, of Cambridge, Mass., where Mr. Leavitt also lived. This joint was then thought to be the final word in joint efficiency and the drawing of the first boiler having it was made in 1879.

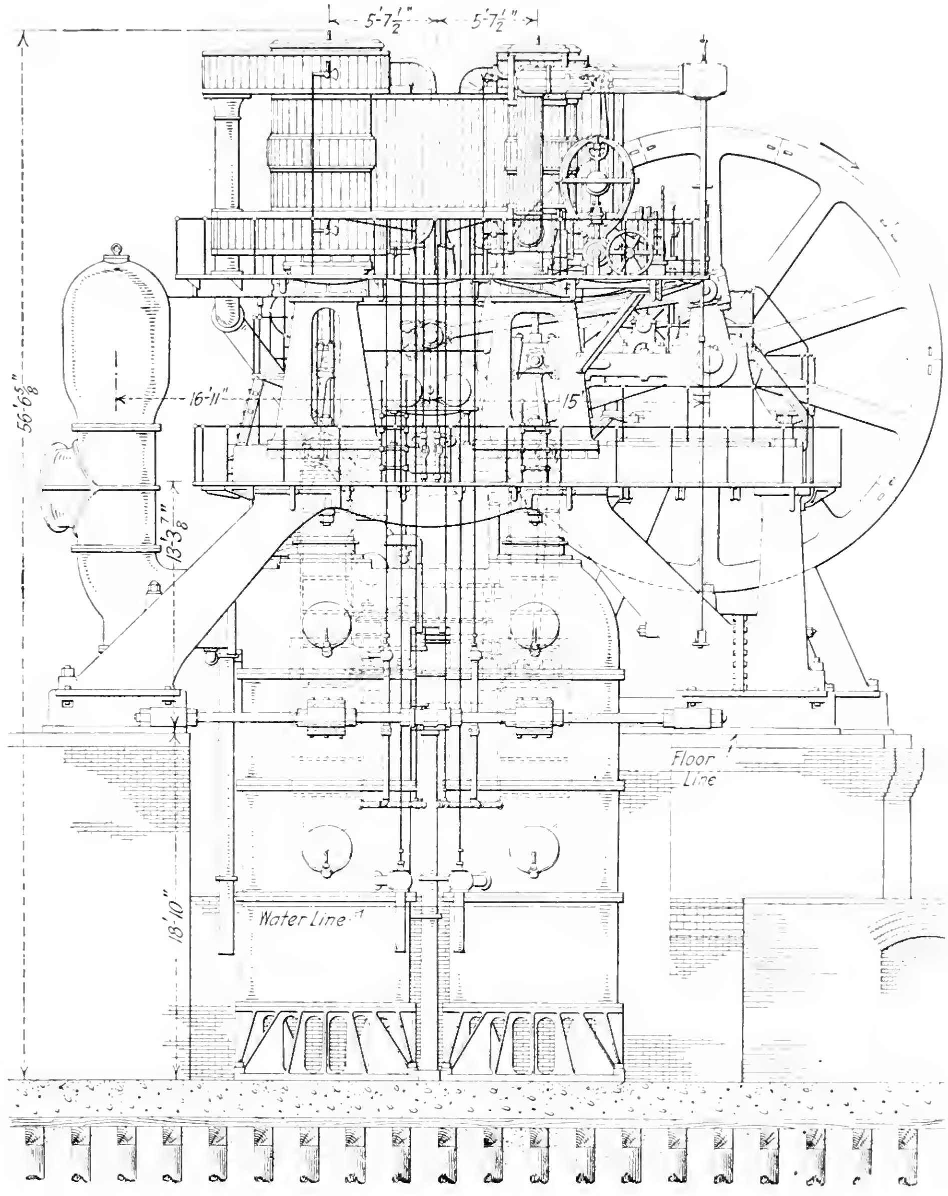

Fig. 7 Michigan Pumping Engine

Why Mr. Leavitt did not adopt English practice in butt joints, with which he must have been acquainted, I do not know, but I suppose that he was seeking a joint of higher efficiency than that, as then designed, which had the straps of equal widths and all rivets in double shear.

The first Belpaire boiler he designed was for 135 lb.; others were designed for 185 lb. pressure. These boilers were very expensive, and as the largest had only 2900 sq. ft. of heating surface, the cost per square foot of heating surface was very high. It was, in fact, about $5.20 in 1887 for 90-in. boilers for 185 lb.

For mill work Mr. Leavitt used the horizontal return-tubular boiler, and some of them 78 in. in diameter carried 185 lb. pressure. For the New Bedford pumping engines he used cylindrical boilers with two Purves furnaces each and 3-in. tubes from the furnaces to a smokebox.

Consulting Engineering

So far as I know, Mr. Leavitt did not do much general expert work, but he acted as consulting engineer for a number of companies. Among them were Henry R. Worthington and the Dickson Mfg. Co. He designed the Penn Avenue shop for the latter company at Scranton, Pa. This was a well-lighted shop with a high center bay and traveling crane, and a gallery on each side.

Mr. Leavitt's influence upon good designing in this country must have been great, and the many draftsmen whom he em-

ployed and who have scattered throughout the country must have exerted a great and silent influence upon excellence in design, which they owe to him. I feel that William Sellers, E. D. Leavitt, John E. Sweet and Charles T. Porter were the best machine designers that this country has produced up to their time. Mr. Leavitt willingly gave credit to the other three for much of his own good work.

According to the *Frankfurter Zeitung*, the newly manufactured compressed cellulose piping has proved very satisfactory in chemical factories and also in mining works. The new material, it is said, is absolutely non-porous, is considerably lighter than iron, can be worked like wood, and is consequently easily moved and repaired. As cellulose is a bad conductor of heat, it requires no particular protection against heat; it also resists chemical influences better than iron. Cellulose tubes are suitable for conducting hot and cold air, and for corrosive gases which eat into iron conductors very quickly. They are not suitable, however, for steam.—*The Engineer* (London), August 17, 1917.

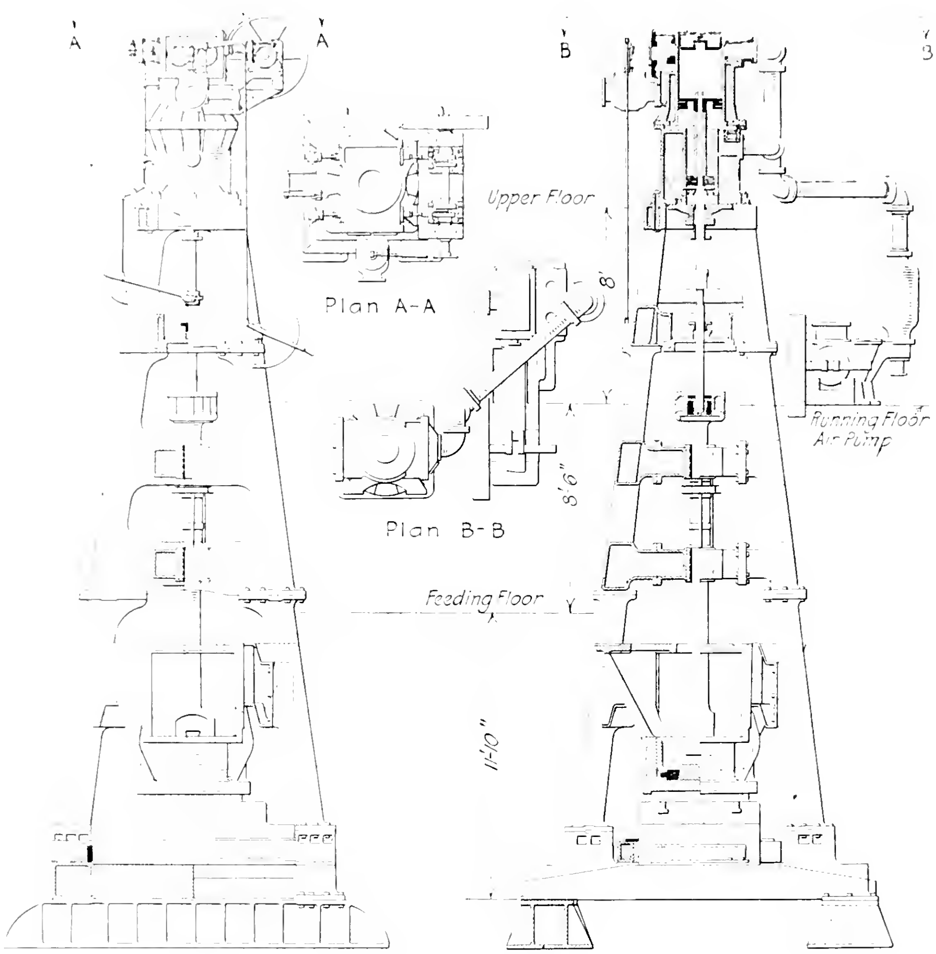

Fig. 8 Leavitt Ore Stamp

Further improvements are unquestionably possible in turbines operating under present conditions, and improvements are also possible in boiler-room equipment and practice, but the results now reached in modern plants are so near to those theoretically attainable under the conditions of operation that no improvements of sweeping magnitude may be expected along such lines. It seems probable that the conditions of operation will have to be radically changed if any great reduction in fuel per unit is to be achieved.

Two revolutionary suggestions to this end have been made within the last few years. It was pointed out by Robert Cramer that increasing the initial pressure by several hundred pounds would make it possible to increase materially the theoretical efficiency of present-day cycles, and S. Z. de Ferranti suggested a new form of turbine cycle in which much greater use was made of superheated steam.

The highest steam pressures now commonly used with steam turbines are in the neighborhood of 200 to 250 lb. per sq. in., and the highest steam temperatures are about 600 deg. fahr., corresponding roughly to about 200 deg. of superheat. The highest pressures for which boilers can be built and the highest temperatures which turbine parts can be made to stand are still unknown. The steam tables carry pressures to 600 lb. abs. and total temperatures to about 1000 deg. fahr.

The suggestion of Ferranti contemplated a radical change of cycle. At the present time it is impossible to say whether turbines will ever be constructed commercially to operate on this cycle. There are many mechanical difficulties to be overcome, but they do not appear to be of as great magnitude as were those that were met and overcome in the early days of turbine construction. It is therefore conceivable that turbines may be built to operate on the Ferranti cycle or some modification thereof.—C. F. Hirshfeld, Mem. Am.Soc.M.E., in *Power*, September 18, 1917.

THE TRUMBLE REFINING PROCESS

A New Departure in the Methods of Oil Distilling, Effecting a Marked Saving in the Percentage of Oil Required as Fuel

By N. W. THOMPSON,[1] SAN FRANCISCO, CAL.

The first step in the refining of oils is to obtain the different fractions or distillates of the crude oil. Some of these are ready marketable products and others need treatment. To obtain these distillates it is necessary to distill or boil them over in a still and separate them according to boiling points.

The old method was to fill a cylindrical still with the crude oil and boil off the lighter distillates, then the next heavier, and so on. After being condensed these distillates were run through a steam still and the still kept to a certain temperature until all of the lighter fraction or first cut was obtained, then the temperature was raised for the next fraction, and so on.

A large number of the refineries at the present time continue this system, and others put a number of crude stills in series and run them continuously,—that is, the residuum or bottoms of the first still run to the second still where they are heated to a higher temperature, and so on to the last still, from which the residuum flows to a cooler and then to the tank. This residuum is generally fuel oil.

In these stills there is a large volume of oil over the fires and also an expensive installation to build and maintain. There can be no seams in the bottom of the stills necessitating very large plates, and it is necessary to have perforated steam pipes in the bottoms to agitate the oil so as to keep the bottoms from burning, etc.

Large surfaces are necessary when the heating is done in this way. There is low heat transfer on account of slow velocities and the low specific heat of the liquid and about one-third of the surface of the still cannot be heated and must be highly insulated to avoid excessive radiation. However, the radiation losses are considerable even in the best settings.

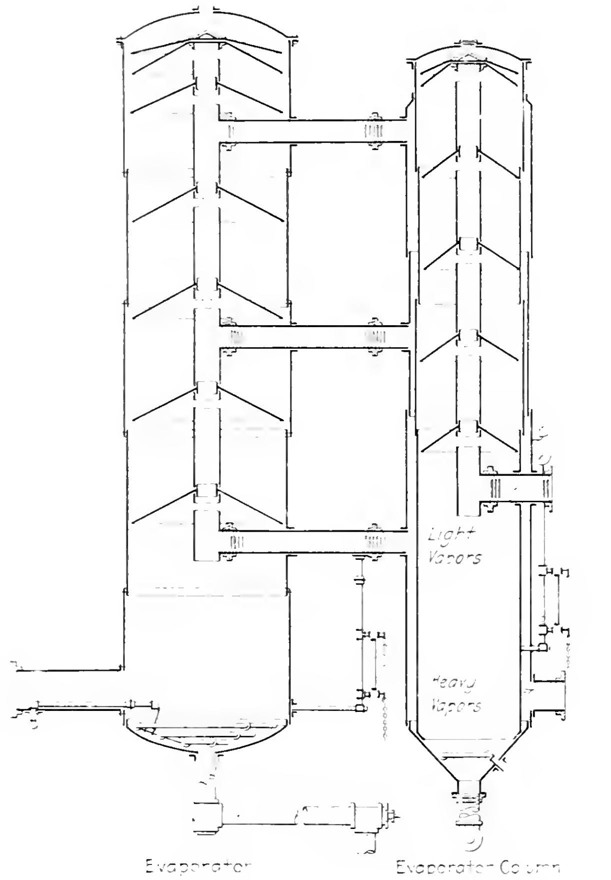

Fig. 1 Evaporator and Evaporator Column

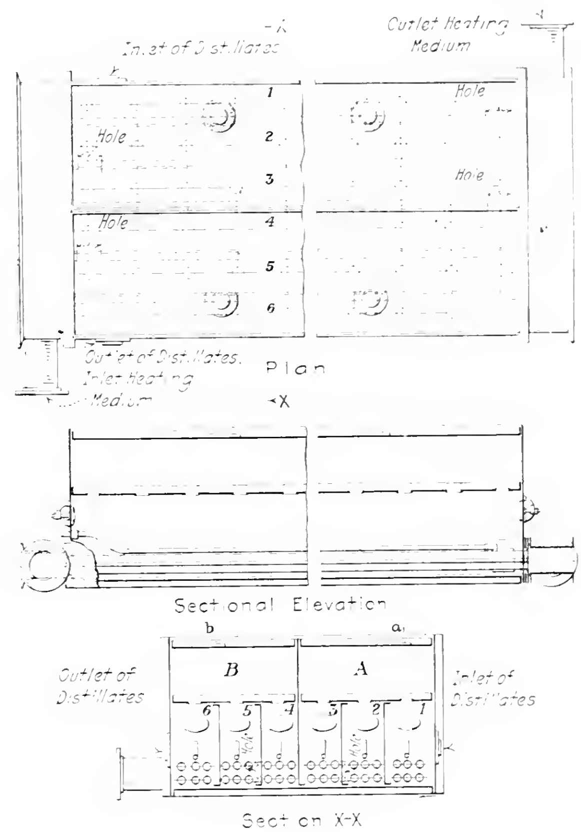

Fig. 2 Separator

The Trumble distilling apparatus is quite a departure from that used in the method described and has proved very successful in the plants where it has been installed. The principal parts of the apparatus are shown in Figs. 1, 2 and 3.

In Fig. 1 is shown a Trumble evaporator, to which in this case is connected an evaporator column. The evaporator con-

[1] Engineer, Simplex Refining Company, San Francisco, Cal.

Presented at a meeting of the San Francisco Section of The American Society of Mechanical Engineers, December 8, 1916. For presentation at the Annual Meeting, December 4 to 7, 1917. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

sists of a closed cylindrical metal shell, vertically disposed, to which heat is applied from the outside in any convenient manner, as for example, by flue gases or by vapors from another evaporator.

Inside the evaporating chamber is arranged a central vertical pipe having umbrella shaped devices attached thereto at intervals, which are called "spreader hoods," so that oil when fed to the apex of these hoods will flow down over their sides in a thin film after the analogy of rain flowing down the outside of an umbrella. The lower edges of these hoods are at a little distance from the sides of the wall of the evaporating chamber, and in operation the oil flows down and over the hood and strikes against the interior wall of the evaporating chamber and flows down the wall in a thin continuous film. In case any of the oil should not strike against the wall in the evaporating chamber, but should drop off the edge of the hood and fall vertically; or in case there should be a tendency to bubbling or foaming on the wall of the evaporating chamber whereby a portion of the oil may be thrown back toward the center of the evaporating chamber, such oil will be caught by the next spreader hood and will flow down the surface thereof, thereby insuring an ultimate spreading of the oil on the wall of the evaporating chamber.

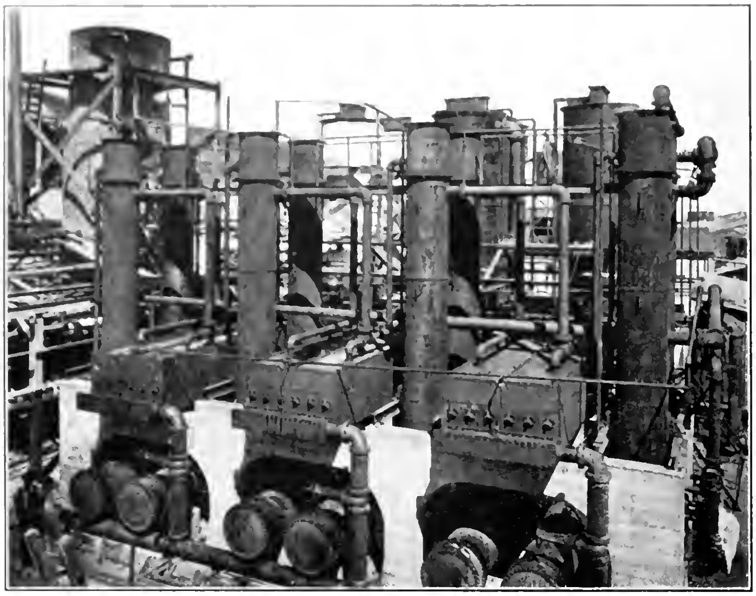

Fig. 3 General Arrangement of Plant

The oil to be operated on is fed through a supply pipe to the top of the evaporating chamber and discharges downward on the apex of the uppermost hood. The oil then flows down this hood in a thin stream and is delivered against the interior wall of the evaporating chamber as above described.

The centrally arranged vapor take-off pipe in the evaporating chamber, to which the spreader hoods are attached, is provided with perforations underneath each of the hoods, and through these perforations the vapors pass from the evaporating chamber into the vapor take-off pipe. Located in this vapor take-off pipe are lateral branch pipes, and these branches extend through the wall of the evaporating chamber to the outside of the apparatus.

Fig. 2 shows the construction of the separator. This is a rerun still for distillates from bottom of dephlegmators, or from any other source, if these need fractioning. The distillate flows into compartment (1) over a number of pipes through which a heating medium is passed, either residuum or vapors as the case may be, and then passes through opening at end of compartment (1) into compartment (2) and back through compartment (3), and so on, leaving at end of compartment (6). The vapors evolved in compartments (1), (2), and (3) pass through openings into vapor compartment A and out through opening a_1 to the condenser or through dephlegmator to condenser, depending upon the fractionation required. The vapors evolved in compartments (4), (5), and (6) pass into vapor compartment B and out through opening b_1, to condenser, etc.

The manifolds on the ends of the separators are provided with covers having stuffing boxes through which valves are operated to regulate the flow through tubes in each compartment, thereby controlling the heat in these compartments.

The illustrations, Figs. 3 to 6 inclusive, are from photographs taken during the construction of a plant employing the Trumble system. Fig. 3 gives a general view. In the foreground, at the left, is the pipe heater and located in the brick stack at the left is the evaporator. In the distance are the dephlegmators, in the foreground the separators and the vertical condensers for the vapors from the separators. Under the arches are the coolers for distillates. The pipe lines in the trench are the distillate lines from the condensers and coolers carrying the cooled products to the receiving boxes. The arrangement of these receiving boxes is shown in Fig. 4. Behind the boxes are dewatering traps for separating the water from the distillates. Fig. 5 shows the dephlegmators with the heat exchangers underneath. Fig. 6 shows the operating valves for the distillates from the dephlegmators. These valves as well as all operating valves are handled from one platform.

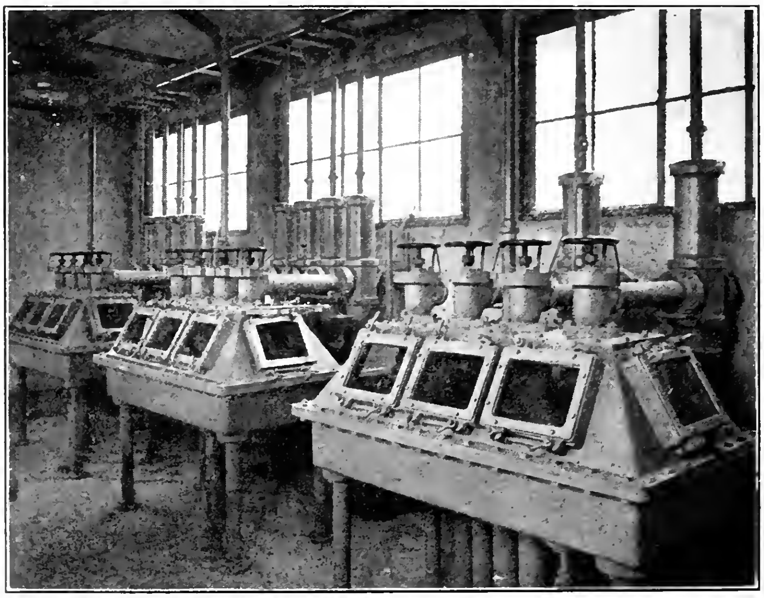

Fig. 4 Arrangement of Receiving Boxes

All plants are designed to meet the conditions under which they are to be used, but they are very flexible and are able to take care of a very wide range of conditions by controlling the heat of the furnace and the velocity of the oil which runs through it. It will be impossible to go into the many different arrangements of plant design but the following will make clear the running of a typical and successful plant.

The flow of the crude oil through the plant is indicated by the flow sheet in Fig. 7. The oil enters through a 6-in. line and is used as a cooling medium in the six coolers shown. These coolers are of the horizontal tubular type, 30 in. in diameter, with sixty-two 2-in. by 18-ft. tubes. The oil enters at the bottom and passes through the tubes, making four passes, and comes out at the top and goes into a header, through which it passes into the four heat exchangers or coolers for the residuum.

These heat exchangers are 48 in. in diameter and have 178 2-in. by 18-ft. tubes. The crude oil enters the first heat exchanger at the bottom and passes through the tubes, making six passes, and out at the top into the bottom of the next exchanger, and so on, to the heater pipes, where it is split in two, each half passing in series through seventy-two 18¾-ft. lengths of 4-in. pipe, flowing back and forth and upward at all times, and then into the top of the evaporator, where it flows down the sides in a thin film.

The oil in passing through the heater pipes and evaporator is heated by the flue gases. The vapors evolved are separated in the evaporator and taken care of later. The oil is maintained at a constant level in the bottom of the evaporator and runs out of the bottom of it as residuum. A perforated steam coil is placed in the bottom of the evaporator under the liquid and superheated steam is passed through it in order to drive off any of the lighter distillates which may drop back from the vapors. However, very little steam is necessary in this case, as the heat losses are supplied by the flue gases.

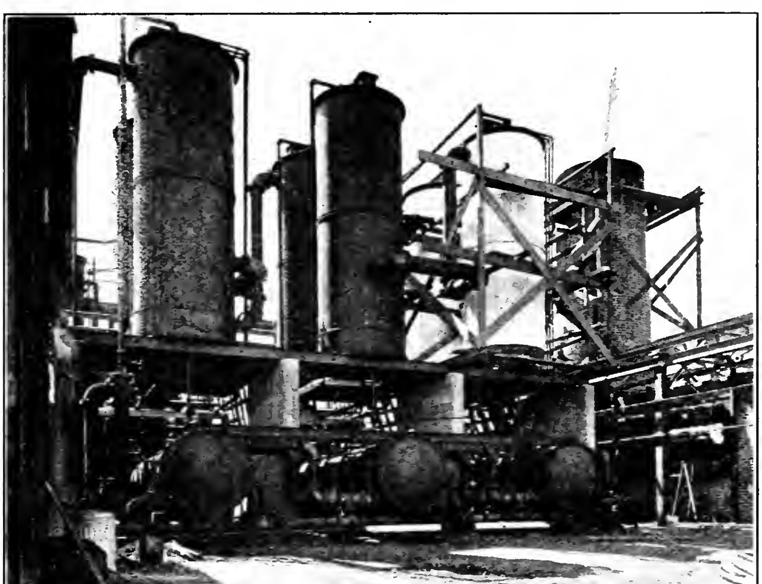

Fig. 5 Dephlegmators with Heat Exchangers Underneath

After leaving the evaporator the residuum is used as a heating medium for redistilling the distillates passing through the separators, and then flows through the heat exchangers countercurrent to the crude oil. The residuum enters the first heat exchanger at the top and makes two passes around the tubes and out at the bottom, then into top of the second exchanger, and so on through the five heat exchangers and through a standpipe, which is vented and which controls the head of residuum in the bottom of the evaporator, and then to the storage tanks.

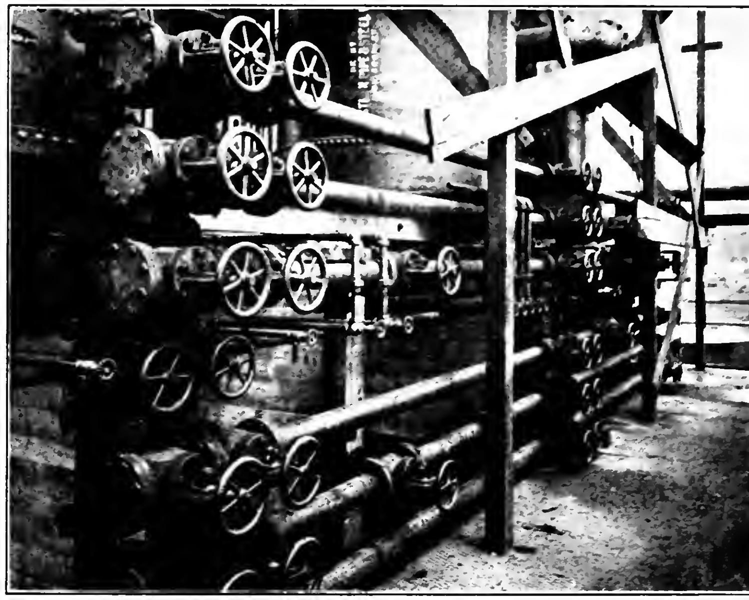

Fig 6 Operating Valves for Distillates from Dephlegmators

Having followed the course of the crude oil through the apparatus, showing the separation of it into vapors and residuum, it remains to dispose of the vapors shown on flow chart in Fig. 8. The vapors from the central vapor column of the evaporator are taken out through a shell and connected into a header. The vapors pass from this header through an oil catcher similar to a steam separator, the condensate passing out of the bottom of it into the bottom of the evaporator. They then pass through six large dephlegmators in series, flowing into the bottom of each and out at the top. In each dephlegmator a partial condensing of the vapor takes place, thus forming a liquid in the bottom of that particular dephlegmator. From some of the dephlegmators this condensed liquid is a ready product; from others it lies just between two different products.

A system of water circulation is used as a cooling medium for the vapors from the dephlegmators and separators. The vapors are cooled in vertical tubular condensers and about twenty barrels of water are required per barrel of distillate cooled. Superheated steam is used in the bottom of the evaporator, separators and dephlegmators as an agitator to relieve the lower boiler point fractions from the bottoms. About 30 lb. per barrel of distillate are produced.

With two Trumble plants in operation continuously for eight months, the company for whom these plants were installed has averaged a run of 16,000 barrels of crude oil per day of 24 hours through both plants, 30 per cent of this crude

oil being vaporized and fractionated into ready marketable distillate products. During this time 1.1 per cent of the total amount of crude oil run was used as fuel to do this work, and the refining losses were 0.75 per cent of the total amount of crude oil run.

Five men are required for operating the two plants per shift, i.e., one head stillman over both plants, one stillman at each plant, one fireman for both plants, and one receiving-house man for both plants.

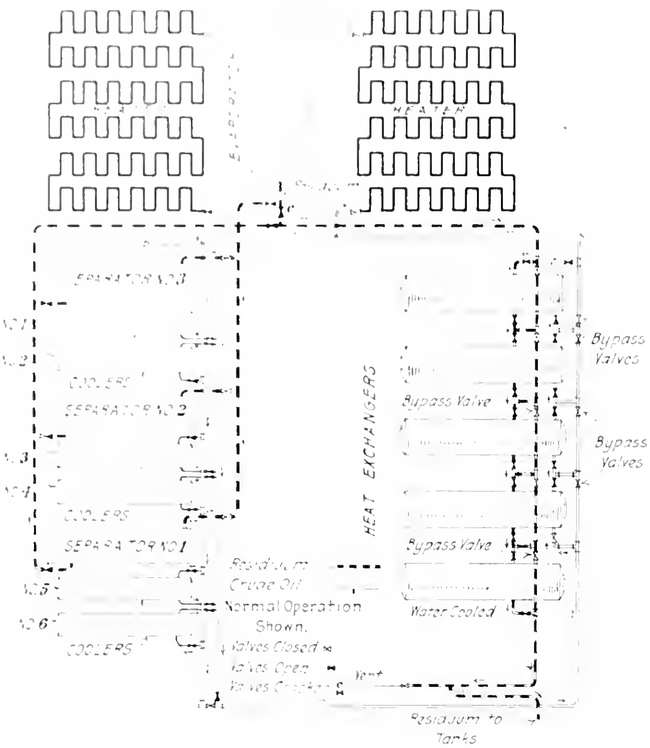

Fig. 7 Crude Oil and Residuum System

At the present time the necessity for conserving the fuel oil and labor around an oil refinery is imperative. The whole subject is a matter of heat units and their proper conservation.

In the Trumble system the products to be re-run in the separators are condensed but not cooled, thereby saving heat. The oil is in a very thin film on the shell of the evaporator and is being heated in its downward flow. The vapors being evolved have a free relief and have no opportunity of dropping back into the residuum.

There is considerable work for the mechanical engineer in conservation of heat units around an oil refinery and in most all branches of the oil industry. There are large refineries operating today and using four to five hundred per cent more fuel than is necessary to do the work. It is possible to save, by proper distribution of the heat available around the oil refineries in the United States, at least 2 per cent of the total crude oil put through these refineries. There are large oil refineries operating today that are using as fuel 4 per cent of the crude oil run through them to do less work than the plant described is doing on 1.1 per cent of the crude oil run through as fuel, and the losses due to non-condensable gases, etc., are 2 per cent against 0.75 per cent.

A typical layout such as is required for accommodating the officers and men at a National Army cantonment comprises, in round numbers, 1500 separate buildings, requiring approximately 30 million feet of lumber. Each cantonment requires a complete system of water supply and sewage disposal, the piping alone for which amounts to more than 50 miles. General warehouses, with necessary trackage, have also been provided. Where the facilities are not available in near-by cities, complete refrigerating and laundry plants have been built.

CROSS-CURRENT PREDETERMINATIONS FROM CRANK-EFFORT DIAGRAMS

A Research Study into the Cause of Excessive Cross-Current Flow Between Paralleled Alternators When Driven by Reciprocating Engines

By LOUIS ILLMER, MILFORD, CONN.

Member of the Society

WHENEVER alternating-current generators are driven by reciprocating engines, the fluctuating crank effort causes oscillatory movements to be superimposed upon the rotating armature parts. In parallel operation, such displacement movements are subject to a peculiar cumulative action, which, under adverse conditions, is liable to become so violent as to drive the armature far out of its course of uniform rotative speed. The present paper deals with the cause and effect of such cumulative action.

Acting alone, the irregular primary crank effort of the reciprocating engines accounts for but a relatively small portion of the excessive displacement movement to which the armature is subjected in parallel operation. Such small armature oscillations do, however, give rise to cross-current forces, which in turn tend to set up independent armature-displacement movements. The combined action of these two distinct periodic forces is likely to superimpose cumulative armature-displacement movements upon the rotating armature of far greater amplitude than could be produced by either component force acting alone.

The method deduced in this paper for arriving at such resultant armature-displacement increments is based upon finding the equivalent effect of the crank-effort and the cross-current-pull forces in terms of their respective sinuous sequence of force application. It will be shown that the actual crank-effort curve of any normal reciprocating engine may be approximated quite closely by means of an equivalent sine curve and that its characteristic accelerating effects may be expressed in terms of fairly simple harmonic-motion formulæ. Furthermore, the independent sinuous oscillations which the periodic cross-current pull tends to superimpose upon paralleled armatures may likewise be taken into account by formulæ of this kind.

It will further be shown that when a sinuous crank effort of a reciprocating engine works against a variable resistance, as fixed by the surging cross-current pull of the generator, the conditions become favorable for imposing cumulative oscillations upon the rotating armature and wheel parts. These parts are then alternately accelerated and retarded by the combined action of two distinct periodic forces, each of which has an independent period and each tends to set up independent armature oscillations. At times these two forces will be acting together, while at other times they will be acting in opposition, thus subjecting the armature and wheel parts to a cumulative oscillation about an imaginary position corresponding to that of uniform rotation.

The derived formulæ make possible the predetermination of the probable ultimate armature-displacement shift as measured from an imaginary reference position, for any given set of assumptions as to characteristics of generator construction, crank effort, and wheel weight. The character and maximum amplitude of the cumulative armature movements are found to depend largely upon the relation between the time period of the sinuous crank-effort curve and that of the cross-current-pull curve. Under normal conditions, the difference in period between these two curves is most readily controlled by the selection of a suitable wheel weight.

When a light wheel is used for paralleled reciprocating engines, the armatures oscillate in a relatively rapid period and the maximum cumulative armature-displacement shift is shown to be approximately twice as large as when a relatively long resultant period of oscillation is obtained by the use of a heavy wheel.

The secondary effects which accompany the use of a light wheel are more likely to upset the engine regulation and in other ways lead to detrimental electrical disturbances. In the event that the wheel weight and governor characteristics are not aptly chosen, the resulting cumulative armature oscillations may set up a heavy cross-current flow of such magnitude as to interfere seriously with the successful operation of the paralleled generators.

The subject will be treated in the following order, viz.:

a Principles underlying harmonic motion and their application in estimating initial armature displacements that result from the uneven primary crank effort of a reciprocating-engine drive

b The effect of such periodic displacement movements upon a single a.c. generator when connected to independent bus bars

c The effect of periodic armature oscillations upon paralleled generators in setting up a variable resistance against which the engine must work; discussion of the cumulative oscillations which are likely to occur whenever a variable load of this kind is driven by the fluctuating crank effort of a reciprocating engine

d Conclusions

e Appendix: Characteristic behavior of an alternating-current generator and other electrical aspects of the parallel-running problem relating especially to cross-current pull and its effects in causing periodic variations in the engine load.

INTRODUCTORY

When a reciprocating engine works against a *constant* load, the increment of flywheel displacement resulting from its uneven crank effort is dependent upon the inertia of the wheel. Its mass is alternately accelerated and retarded in proportion to the undulating character of the crank-effort forces, and for present purposes the resultant change in the wheel velocity may be taken as a convenient measure of such crank-effort irregularity.

For presentation at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 4 to 7, 1917. The paper is here printed in abstract form and advance copies of the complete paper may be obtained gratis on application. All papers are subject to revision.

The average wheel velocity may be assumed to coincide with that of an imaginary wheel rotating at absolutely uniform speed, such that any velocity change induced by the variable crank effort will cause the actual wheel to lag or lead with respect to the virtual position fixed by the reference standard.

Expressed mathematically, the foot-pounds of energy absorbed in raising the flywheel velocity from V_2 to V_1 is

$$\frac{1}{2}m\,(V_1^2 - V_2^2) = m\left(\frac{V_1 + V_2}{2}\right)(V_1 - V_2) = 2\,mV_0v_0 = \Delta W_0 \ldots [1]$$

where $V_0 = (V_1 + V_2)/2$ = reference standard for uniform rotation, i.e., synchronous speed as measured by the average crankpin velocity in ft. per sec.

$v_0 = (V_1 - V_2)/2$ = maximum crankpin velocity change as measured with respect to the reference standard V_0

$2v_0/V_0 = \delta_0$ = coefficient of speed fluctuation as determined from the primary crank-effort diagram

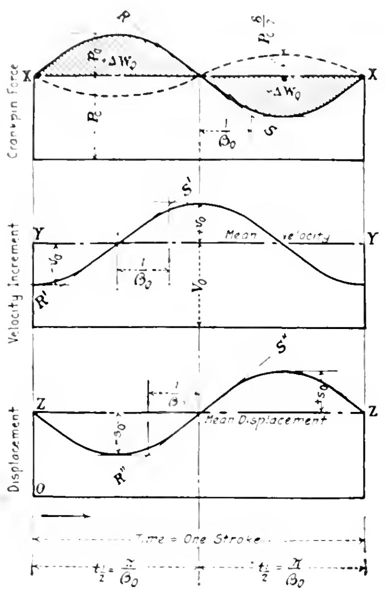

FIG. 1 SINUOUS CRANK-EFFORT DIAGRAMS

$m = \frac{G}{g}\left(\frac{\rho}{R}\right)$ = equivalent units of wheel mass transferred to the *crankpin* radius R.

$\Sigma\frac{G}{g}\rho^2$ = equivalent moment of inertia of the crankshaft weights, g being gravity acceleration at 32.2 ft. per sec. per sec.

G = equivalent rim weight of wheel, lb., which is equal to the weight of the rim plus about 1/10 rim weight for arm allowance, plus the armature weight as transferred to the center of gravity of the wheel rim ρ.

ΔW_0 = foot-pounds of fluctuating energy as measured by one-half the total lobe areas enclosed by the crank-effort diagram per stroke

Assuming a reciprocating engine to work with a sinuous crank effort, the phase relation between the velocity change and displacement increment which it imparts to the wheel is shown in Fig. 1. The common abscissa is taken on a time basis which is proportional to the travel of the crankpin.

The upper sine curve represents the variable crank-effort force drawn about the base line XX, which ordinate represents the mean turning force P_c acting normal to the crankpin radius. The sectional area $\pm\Delta W_0$ denotes the fluctuating energy that must be successively taken up and given out by the flywheel parts in order to equalize the sinuous crank effort.

The resulting velocity change as measured at the crankpin is indicated by the sinuous line superimposed upon the mean or synchronous velocity base YY. The sequence of the displacement increments is indicated by the lower sine curve plotted with respect to the base line ZZ, which represents the reference position assumed by the crankpin when rotating at the uniform synchronous speed V_0.

Restricting the interplay of the fluctuating energy ΔW_0 to that exchanged during any one stroke period of the engine, the coefficient of energy fluctuation becomes equal to

$$K = \Delta W_0/W_0 \ldots\ldots\ldots [2]$$

where

K = coefficient of energy fluctuation, which is also equal to one-half the mean ordinate of the lobe area ΔW_0 divided by mean turning effort P_c

$W_0 = P_c \times \pi R$ = foot-pounds of effective work done per stroke, i.e., mean engine turning effort P_c multiplied by the crankpin path during one stroke

P_c = b.hp. $\times\, 550/V_0$ = average crankpin force (in lb.) acting normal to the crankpin radius R, measured in feet.

HARMONIC-MOTION FORMULÆ

A sinuous crank effort, as measured with respect to the mean axis XX of Fig. 1, sets up a change in the synchronous velocity of the rotating-wheel parts within the limits $V_0 - v_0$ and $V_0 + v_0$, in accordance with the law of simple harmonic motion. The principles underlying such motion are easily established since the average ordinate of the sine-lobe area ΔW_0 bears a simple fixed relation to the maximum accelerating force P_0.[1]

[1] Starting with the general equation for accelerated motion,

$$a_0 = P_0/m \ldots\ldots\ldots [3]$$

where

a_0 = maximum acceleration acting upon the mass m as measured in ft. per sec. per sec.

P_0 = maximum accelerating force in pounds, as measured at the middle of the sinuous crank-effort lobe.

Since the average ordinate under the sectioned sine lobe ΔW_0 is equal to $(2/\pi)P_0$, the maximum velocity increment will be

$$v_0 = (2/\pi)\,a_0t_m \ldots\ldots\ldots [4]$$

where

t_m = time equivalent one-half length of the sine lobe as measured in seconds, which in angular measure corresponds to $\pi/2$ radians.

The resulting maximum displacement being proportional to the average velocity change multiplied by time, it follows that

$$s_0 = (2/\pi)\,v_0t_m = (2/\pi)^2\,a_0t_m^2 \ldots\ldots\ldots [5]$$

where

s_0 = maximum linear displacement or amplitude of oscillation (in ft.) resulting from a sinuous velocity change whose maximum is v_0.

As a further condition for simple harmonic motion, the maximum acceleration a_0 must be directly proportional to the displacement s_0, which expressed mathematically takes the convenient form

$$a_0 = \beta_0^2s_0 \ldots\ldots\ldots [6]$$

where

β_0^2 = specific acceleration of the sinuous crank effort at unit displacement, as measured with respect to the synchronous reference position ZZ of Fig. 1.

For the critical value $s_0 = 1$ ft., the factor a_0 becomes equal to β_0^2; substituting this value in [5] and transposing, the following relation is obtained, which shows that the time period for harmonic motion is independent of its amplitude; thus,

$$t_m = \pi/2\beta_0;\quad t_n = \pi/\beta_0;\quad t_1 = 2\pi/\beta_0 \quad\ldots\ldots [7]$$

where t_m, t_n and t_1 are the respective times of a quarter, half and complete period of harmonic oscillation.

It will be seen that the constant β_0 converts the time factor into angular or π measure. It also fixes other important characteristics of simple harmonic motion, as is evident from the following substitution in Equation [4], viz.:

$$v_0 = (2/\pi)\,a_0\,(\pi/2\beta_0) = a_0/\beta_0 = \beta_0 s_0 \quad\ldots\ldots [8]$$

When a body oscillates harmonically, the characteristic relations existing between the acceleration, velocity and displacement factors are definitely fixed by the basic constant β_0 as given in Equation [8].

Applying these deductions to the case of a sinuous crank-effort diagram for a single-cylinder engine, the time period of a complete oscillation is that required for one stroke, which is equal to

$$t_1 = 60/2N = 2\pi/\beta_0 \quad\ldots\ldots [9]$$

where N = revolutions per minute.

The corresponding basic value of the primary crank-effort constant β_0 may be found by substituting the above value of t_1 in Equation [7]; thus,

$$\beta_0 = 2\pi/(30/N) = 0.21\,N \quad\ldots\ldots [10]$$

The other basic values required to characterize the harmonic wheel motion set up by a sinuous crank effort when making a complete oscillation in a time period of one stroke as per

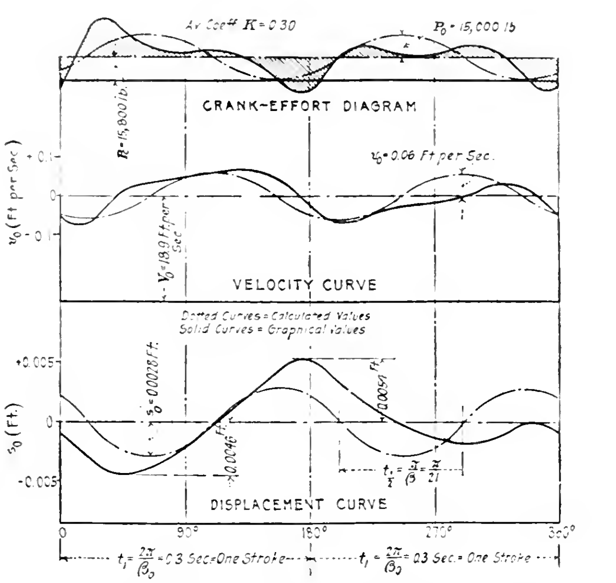

FIG. 2 CRANK-EFFORT DIAGRAMS FOR SINGLE-CYLINDER 500-B.HP. KOERTING GAS ENGINE

Cylinder dimensions, 25 × 43⅜ in.; speed, 100 r.p.m.; piston-rod diameter 6½ in.; wheel weight at 17½ ft. outside diameter, 24,000 lb.; equivalent mass m at crankpin, 12,000 units; load condition, maximum.

Eq. [9], may be found by substituting in Eq. [1]; thus,

$$v_0 = \Delta W_0/2mV_0 = \beta_0 s_0 \quad\ldots\ldots [11]$$

where $V_0 = 2\pi RN/60$ = mean crankpin velocity in ft. per sec.

v_0 = maximum velocity increment superimposed upon V_0

s_0 = corresponding maximum displacement (in ft.) as measured from the synchronous reference position ZZ.

For a single-cylinder engine the pitch length of its crank-effort lobe, i.e., the space passed over by the crankpin in the time period of one-half stroke, is equal to $\pi V_0/\beta_0$, and since $(2/\pi)P_0$ represents the average accelerating force acting upon the crankpin during this period, then

$$\Delta W_0 = \frac{2}{\pi}P_0\left(V_0\frac{\pi}{\beta_0}\right) = \frac{2P_0V_0}{\beta_0} = 2mV_0v_0 \quad\ldots\ldots [12]$$

In a similar manner it will also be found that

$$\Delta W_0 = KW_0 = KP_cV_0\,(2\pi/\beta_0) \quad\ldots\ldots [13]$$

For a single-cylinder engine the maximum velocity increment v_0 may be found in terms of known constants by substituting the above values in Eq. [11]; thus,

$$v_0 = \frac{2\pi KP_cV_0}{\beta_0}\cdot\frac{1}{2mV_0} = \frac{\pi KP_c}{m\beta_0} = \beta_0 s_0 \quad\ldots\ldots [14]$$

From the above it also follows that

$$P_0 = m\beta_0^2 s_0 = \pi KP_c \quad\ldots\ldots [15]$$

Fig. 2 shows that the average results obtained graphically from an actual single-cylinder crank-effort diagram can readily be evaluated on the basis of the sine-curve approxi-

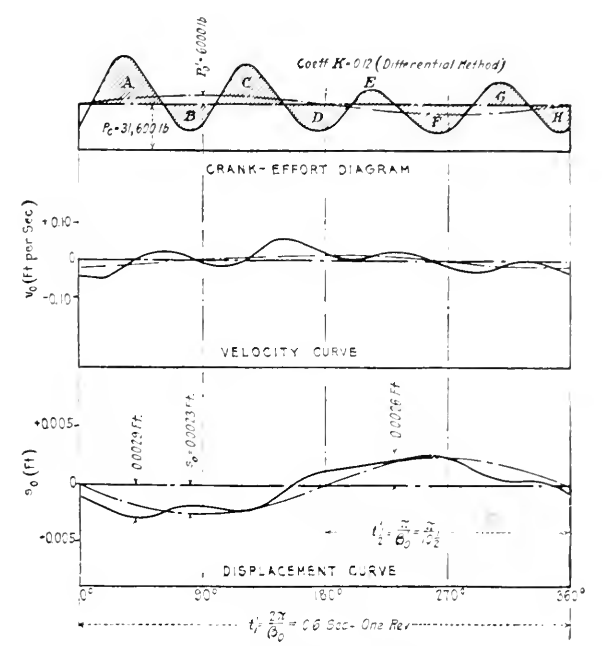

FIG. 3 CRANK-EFFORT DIAGRAMS FOR TWIN-CYLINDER 2 x 500-B.HP. KOERTING GAS ENGINE

Cylinder dimensions, 25 × 43⅜ in.; wheel weight at 17½ ft. outside diameter, 48,000 lb.; equivalent mass m at crankpin, 24,000 units; load conditions, maximum.

mation, and that the resulting average velocity and displacement increments may be determined with a fair degree of accuracy by means of the given equations. This figure represents a crank-effort diagram for a single-cylinder 500-b.hp. double-acting Koerting gas engine operating at maximum load.

A corresponding diagram for a set of twin-cylinder engines of the same make and size is shown in Fig. 3. In both diagrams due allowance has been made for the inertia effect of the reciprocating parts, angularity of connecting rod, and the like.

ARMATURE-DISPLACEMENT INCREMENTS FOR SINGLE NON-PARALLELED GENERATOR UNITS

It is to be borne in mind that the harmonic-motion formulæ thus far deduced apply only to the case of a reciprocating engine whose sinuous crank effort works against a *uniform* or straight-line resistance XX, such as would be encountered in a lineshaft drive and the like.

These simple relations may be materially modified when reciprocating engines are used to drive alternating-current generators, especially those connected in parallel. In that event the armature oscillations resulting from the irregular crank effort set up a periodic cross-current pull which is capable of producing a cyclic variation in the engine load. This reactive effect is dependent upon the characteristic behavior of the driven a.c. generator, the essential features of which are best represented graphically by means of vector diagrams as elucidated in the Appendix included in the full paper.

Touching upon the principles underlying electric-power generation by means of an alternator, it may be pointed out that such a generator running at synchronous speed can only deliver current to the bus bars when the armature is made to lead with respect to the neutral position assumed by the armature when running at no load. That is to say, the application of engine power forces the armature ahead of this neutral phase position by a certain angular displacement lead such that it will still be running at synchronous speed but out of phase with its neutral phase position by an angular displacement lead $+\alpha_0$, on the other hand, when an external resisting force causes the armature to lag with respect to the neutral phase position by an angle $-\alpha_0$, this reverse action will convert the machine into a synchronous motor.

TABLE 1 COMPARATIVE DISPLACEMENT VALUES FOR SINGLE ENGINE

Items	Estimated by Formulæ	Graphical Determinations
P_c	15,800 lb.	....
β_0....	21	....
K...	0 30	0 24 to 0.39
P_0......	15,000 lb.	10,000 to 27,000 lb.
ΔW	27,000 ft-lb.	20,400 to 33,200 ft-lb.
$(2\pi v)$ (avg. velocity) ...	0 038 ft. per sec.	0 011 ft. per sec.
$(2\pi s_0)$ (avg. displacement)....	0 0018 ft.	0 0021 ft.

As explained in the Appendix, the mean angular displacement lead α_0 is dependent upon the construction characteristics of the alternator and serves as a measure of the full-load output delivered by this type of generator. Assuming the driving torque and output to remain constant, then the uniformly rotating armature will maintain a constant lead angle α_0 with respect to its neutral or no-load phase position. In case, however, the generator is driven by a reciprocating engine, its irregular crank effort will cause a periodic shift in the armature displacement equal to $\pm\alpha_x$, as measured with reference to the mean lead angle α_0.

Applying these deductions to the case of a *single* alternating generator driven by a reciprocating engine, the resulting speed fluctuation as measured by the coefficient δ_0 will cause the armature lead angle to vary within the limits $\pm\ {}^1\!/_2\,\delta_0\alpha_x$. This periodic shift in the armature lead angle α_0 serves to produce a corresponding change in the generator output. Hence the effect of varying the resistance against which the engine has to work may be embodied in its crank-effort diagram by substituting a sinuous curve for the straight base line XX of Fig. 1. As shown dotted, the phase and period of this new resistance curve for a single-cylinder unit coincide with those of its primary displacement curve, while the amplitude of such initial armature oscillation may be fixed at ${}^1\!/_2\,\delta_0 P_c$, as plotted upon the reference line XX.

CUMULATIVE DISPLACEMENT EFFECTS FOR PARALLELED GENERATOR UNITS

Turning now to the electrical conditions under which alternators operate in parallel, such armatures are no longer locked with the external circuit in the manner of a single generator; instead, the electrical tie assumes characteristics closely analogous to those of a flexible coupling between the two paralleled armature shafts, all of which is rather fully set forth in the Appendix.

The flexible nature of this coupling allows one of the paralleled armatures to lead periodically with respect to its mean lead angle α_0, provided the other armature simultaneously lags with respect to its α_0 by an approximately equal angular displacement shift α_x. This difference in armature positions sets up an equalizing or cross-current flow between the generators whereby the lagging armature may momentarily generate less power than its mate without materially affecting the combined output delivered to the common bus bars.

The cross-current pull is, however, capable of superimposing oscillations of considerable magnitude upon the rotating armature. The amplitude of such oscillations is generally much larger than was found to be the case for the single generator connected to independent bus bars.

It will now be shown that this increment of displacement is due to the cumulative action which results in parallel generators whenever the variable generator load, as fixed by the periodic cross-current pull, is combined with an uneven sinuous crank effort having a different period.

The resultant periodic armature oscillation produced by the combined action of two such forces, i.e., excess crank effort P, and cross-current pull P_{cc}, is likely to become cumulative when the period of the pull P_{cc} bears certain critical relations to the period of the force P_0.

As given by Eq. [A] of the Appendix, the factor P_{cc} as taken in terms of the mean crankpin force P_c is equal to

$$P_{cc}/P_c = (\sin \alpha_x/\sin \alpha_0) \cos \alpha_0$$

Owing to the relatively small angular armature displacements permissible in good practice, the mathematical treatment of this portion of the discussion may be much simplified by substituting angular measure for the sine values of the lead and shift angles α_0 and α_x, and by further assuming that the value of $\cos \alpha_0$ in the above equation may be taken as equal to unity without serious error. On the basis of this approximation, Eq. [A] reads

$$P_{cc}/P_c = \alpha_x/\alpha_0 = s_x/s_0$$

or

$$P_{cc}/s_x = P_c/s_0 = F = m\,\beta_x^2 \ldots\ldots\ldots\ldots [16]$$

where α_0 = mean angular displacement lead of the armature as measured in electrical radians

α_x = angular displacement shift of the armature as measured with respect to mean lead position α_0

$s = \alpha_0 R$ = arc length in feet, corresponding to the armature-displacement lead angle α_0 as measured at the crankpin circle

$s_x = \alpha_x R$ = arc length in feet, corresponding to the armature-displacement shift angle α_x.

In the above equation the constant F represents the specific accelerating force (in lb.) of the cross-current pull when the linear displacement $s_x = 1$ ft., as measured at the crankpin circle. Eq. [16] further shows that the cross-current pull P_{cc} may be taken as directly proportional to the linear shift s_x

and that it becomes approximately equal to the mean engine turning force P_c when $s_x = s_a$. The constant β_x fixes all of the characteristic relations of the harmonic armature movements resulting from the action of the cross-current pull except that of the amplitude limit.

Since the angles α_0 and α_x are measured in electrical radians, Eq. [16] may also take the form

$$\frac{F}{m} = \beta_x^2 = \frac{P_c}{m}\cdot\frac{n}{Ra_0}\ldots\ldots\ldots\ldots\ldots\ldots[17]$$

where β_x^2 = specific acceleration of the cross-current pull at $s_x = 1$ ft. linear armature displacement as measured at the crankpin circle

$\pi R/n$ = generator pole pitch as measured (in ft.) at the crankpin circle = π electrical radians.

n = number of pole pairs = cycles per sec. $\times(60/N)$.

The resulting cross-current pull corresponding to a given armature shift s_x is dependent upon the constructive characteristics of the generator, which are largely fixed by the

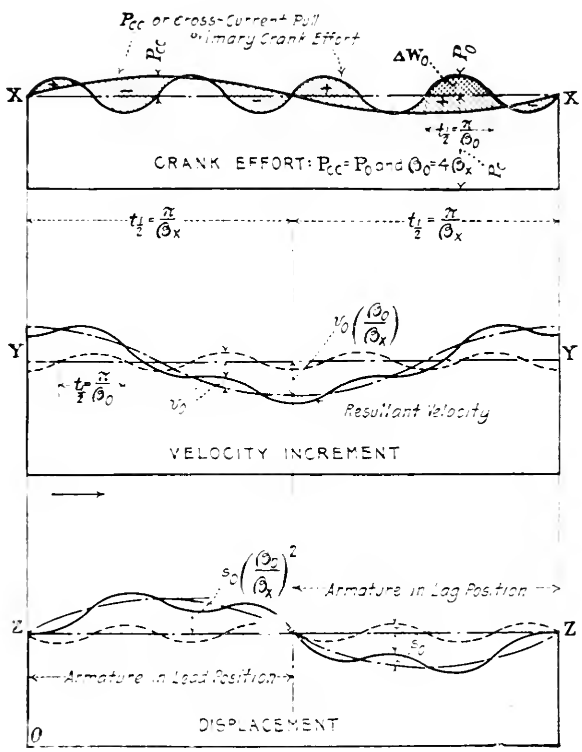

FIG. 4 DIAGRAM SHOWING CUMULATIVE EFFECT OF CROSS-CURRENT PULL FOR $\beta_0/\beta_x > 7/2$

value of s_a. Accordingly, the relation of the basic constants β_0 to β_x may also be expected to be dependent upon the factor s_x. For single-cylinder engines the numerical value for this relation may be arrived at as follows:

Transposing Eq. [14] to the form $\beta_0^2 = \pi K P_c/ms_0$ and dividing by Eq. [17], gives

$$\frac{\beta_0}{\beta_x} = \sqrt{\frac{(\pi K/s_0)}{(n/Ra_0)}} = \sqrt{\pi K\frac{s_x}{s_0}} = 0.21\,N\sqrt{\frac{Ra_0}{n}\cdot\frac{m}{P_c}}\ldots\ldots[18]$$

When $\beta_0' = \frac{1}{2}\beta_0$, the corresponding equation for twin-cylinder engines becomes equal to

$$\frac{\beta_0'}{\beta_x} = 0.105\,N\sqrt{\frac{Ra_0}{n}\cdot\frac{m}{P_c}}\ldots\ldots\ldots\ldots[18a]$$

The above equations fix the vital relations required for cross-current determinations in paralleled generators; they show that the important ratio of the constants β_0/β_x is independent of the coefficient K, and secondly that this ratio is largely dependent upon the speed factor N.

Since the value of the primary displacement s_0 is usually quite small in comparison with s_a, the period of oscillation set up by the cross-current pull when acting alone is a relatively long one, being equal to

$$t_{\frac12} = \pi/\beta_x \quad\ldots\ldots\ldots\ldots[19]$$

It will be seen that the paralleled armatures are acted upon by two distinct periodic forces, i.e., excess crank effort and cross-current pull, whose time periods are π/β_0 and π/β_x, respectively. Each of these forces tends to set up independent oscillations, but they combine to swing the armatures in a

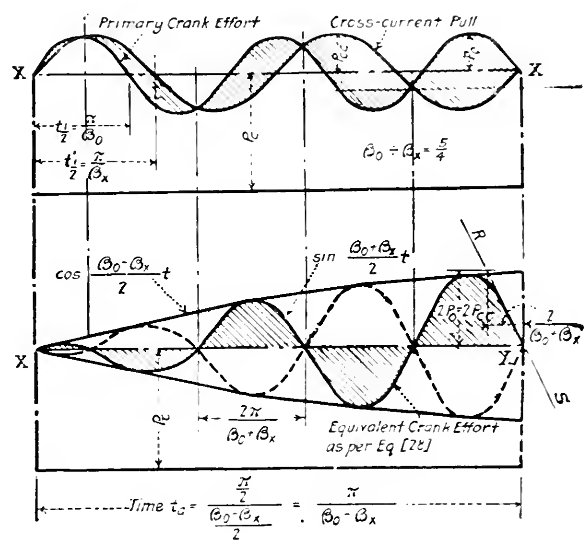

FIG. 5 DIAGRAM SHOWING CUMULATIVE EFFECT OF CROSS-CURRENT PULL FOR $\beta_0/\beta_x > 7/2$

resultant period which may be found by replacing the straight resistance line XX of the crank-effort diagram by a sinuous resistance or load curve having a relatively large amplitude equal to the cross-current pull P_{cc}, as indicated in Fig. 4.

In the case of paralleled generators, the resultant sectioned lobe area of the crank-effort diagram is to be taken with respect to the resultant sinuous resistance line P_{cc}, since this area fixes the period and generally determines the character of the final armature movements.

The cross-current pull will continue to superimpose cumulative oscillations upon the rotating armature, until the condition of indifferent equilibrium is finally reached where $P_{cc} = P_0$.

The consideration of this problem may be further simplified by taking into account only the two limiting conditions as to time of oscillation: namely, (1) the case in which the ratio of β_0/β_x is a relatively large one, i.e., 7/2 or over, by which assumption the period and amplitude of the cross-current pull is made to dominate and fix the character of the resulting armature movements as shown in Fig. 4; and (2) the case in which the factors β_0 and β_x are approximately equal, the effect of which is to produce a series of comparatively rapid armature oscillations, whose amplitude rises and falls periodically in accordance with the sine law, as indicated in Fig. 5.

CASE I: CUMULATIVE ARMATURE DISPLACEMENTS FOR $(\beta_0/\beta_x) > 7/2$

Taking up the first of these cases in detail and referring to Fig. 4, the average velocity change produced upon the armature and wheel parts will be a function of the resultant sectioned area lying between the crank effort and the sinuous resistance or load curves. For the condition that $P_{cc} = P_x$, it will be apparent that the total area under one of the cross-current or P_{cc} sine lobes as measured with respect to its straight base line XX becomes equal to $(\beta_0/\beta_x)\Delta W_0$, i.e., equal to the sum of all the ΔW_0 lobe area enclosed by the primary crank effort curve in the time period π/β_x. If then such a cross-current pull were acting alone upon the armature parts, the energy absorbed during the time period $\pi/2\beta_x$ would, according to Eq. [1], impart a maximum velocity change equal to $(\beta_0/\beta_x)v_0$. This value serves to fix the amplitude of the fundamental velocity curve shown dotted and dashed in Fig. 4.

The cross-current pull when acting alone may be expected to set up armature oscillations closely following the laws of simple harmonic motion, because the accelerating force P_{cc} is approximately proportional to the displacement shift s_x. In addition to this motion, the irregularity of the crank effort sets up independent sinuous velocity changes of smaller magnitude as drawn dotted upon the axis YY, which superimposed upon the fundamental curve produces the resultant velocity shown by the full-lined curve of Fig. 4.

The corresponding maximum linear armature-displacement shift resulting from the combined action of the cross-current pull and irregularity of crank effort, becomes equal to

$$s_x = v_x/\beta_x = s_0(\beta_0/\beta_x)^2\,[1 + (\beta_x/\beta_0)] \;\ldots\ldots \qquad [20]$$

by Eq. [18] $= \pi K s_0 [1 + (\beta_x/\beta_0)]$ for a single-cylinder engine.

Equation [20] fixes the actual limiting displacement shift s_x that may be expected when two paralleled alternators have settled into equilibrium as regards the interchange of cross-current energy.

The corresponding mean shift angle α_{xav} measured with respect to α_0 becomes approximately equal to

$$\alpha_{xav} = \frac{2}{\pi}\frac{s_0}{R}\left(\frac{\beta_0}{\beta_x}\right)^2\left(1 + \frac{\beta_x}{\beta_0}\right) = \frac{2}{\pi}\,\alpha_x\left(1 + \frac{\beta_x}{\beta_0}\right) \qquad [21]$$

This angle α_{xav} is fixed by the average ordinate of the sectioned area lying between the crank effort and the sinuous load curve as indicated in Fig. 4.

The correctness of the above deductions has been checked by means of actual cross-current measurement tests conducted upon a set of single-cylinder 500-b.hp. Koerting gas engines having heavy flywheels and driving three-phase alternators on an induction-motor load.

The crank-effort diagram for these engines is almost identical with that given in Fig. 2. The comparative results attained with these two similar units, running at a practically constant load, are given in Table 2.

The pulsations recorded by the ammeter readings, as measured from maximum to maximum, showed 35 to 38 beats per min. as against an estimated period for such beats of $2\pi/\beta_x =$ 1.9 sec., or about 32 beats per min.

CASE II: CUMULATIVE DISPLACEMENTS FOR $(B_0/B_x) < 7/2$

The foregoing formulæ for the displacement shift angle α_x were based upon the condition that the ratio β_0/β_x shall not fall below the critical value 7/2. At this juncture the time periods of the crank-effort and of the generator-load curves become more nearly equal, and as a result the combined or resulting sectional area lying between these curves assumes an essentially different character from that shown in Fig. 4. The armature movements which take place when the ratio of β_0/β_x is relatively small are still found to act cumulatively until the cross current pull p_{cc} reaches its critical value P_0, but the effect produced is a series of rather rapid armature oscillations which periodically rise and fall in amplitude as indicated in Fig. 5. In order that such armature movements may occur without giving up energy to the external power circuit, one of the paralleled armatures must lead at approximately the same instant that its mate lags, in the manner shown respectively by the full- and dotted-lined oscillations in the lower crank-effort diagram.

The equation for any ordinate P_x of the sectional area lying

in the upper crank-effort diagram of Fig. 5 takes the following form:

$$P_x = P_0\,(\sin\beta_x t + \sin\beta_0 t)\ldots\ldots\ldots\ldots\ldots [22]$$

Combining the factors of this equation on the basis of the trigonometrical relation for the sum of sine values,

$$P_x = 2P_0\left(\sin\frac{\beta_0+\beta_x}{2}t\,\cos\frac{\beta_0-\beta_x}{2}t\right)\ldots\ldots\ldots\ldots [23]$$

This equation, as graphically analyzed in the lower crank-effort diagram, shows that the component oscillations as fixed by the sine factor vibrate cumulatively within the limit line fixed by the cosine factor. The time period of the component oscillation is determined by the mean value of β_0 and β_x, while the period of the limit line is fixed by their difference. The characteristics of the resulting velocity and displacement curves will be identical with those of the equivalent crank-effort curve shown in the lower diagram.

The time required for the cumulative oscillations to change from minimum to maximum amplitude is equal to

$$t_a = \pi/(\beta_0 - \beta_x)\ldots\ldots\ldots\ldots\ldots\ldots [24]$$

which holds good for all values of β_0/β_x less than 3 and greater than unity. The maximum velocity increment attained by the wheel parts due to the accumulation of energy cannot

at any time exceed the energy equivalent of the sectioned area as fixed by the largest one of the sin $\frac{1}{2}(\beta_0 + \beta_x)$ lobes, shown in Fig. 5. The corresponding maximum acceleration is limited to $2P_0/m$, and since the resulting velocity is proportional to $1/(\beta_0 + \beta_x)$ and not to $1/(\beta_0 - \beta_x)$, it will be seen that even for long periods that accompany small differences of β_0 and β_x the cumulative energy does not under any conditions tend to produce an infinite armature deflection. This point is brought out because Bonte,[1] among others, has advanced contrary views as based upon the Rosenberg theory previously discussed.

For the cumulative oscillatory movements indicated by Fig. 5 the maximum angular displacement shift cannot exceed

$$\alpha_x' = \frac{2P_0}{P_c}\alpha_0 = \frac{2P_0}{P} \cdot \frac{san}{R} \qquad [25]$$

$$\alpha_{x\,av}' = \frac{2P_0}{P_c}\alpha_0\left(\frac{2}{\pi}\right)^2 - \frac{2}{\pi}\left(\frac{\alpha_x'}{2}\right)^4_\pi \qquad [26]$$

The deductions embodied in the last two equations have been checked by the graphical determinations shown in Fig. 6, as based upon the assumed specifications noted below. These curves were kindly worked out for the author some years ago by Mr. Erich C. Rassbach. At that time the present mathematical basis had not yet been developed, and in order to determine the probable course of the resultant armature oscillations for small values of β_0/β_x, it became necessary to resort to a tedious graphical solution. The comparative figures given in Table 3 show satisfactory agreement.

The principles underlying the formulæ herein developed may also be used in solving the more general problems relating to cumulative oscillatory movements, such as are involved in hunting rotary converters and the like.

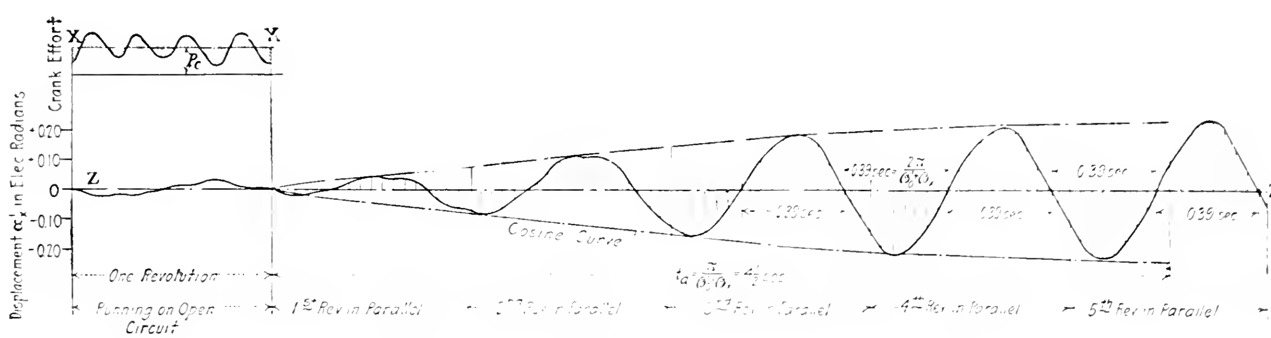

Fig. 6 Graphical Determination of Cumulative Armature Oscillations for $\beta_0/\beta_x = 1.09$

The measured cross-current flow is determined by the average armature-displacement shift, and while α_x' for Case II is approximately twice as large as α_x as found for Case I, the average shift is almost identical with that given by Eq. [21], as is evident from the following relation:

TABLE 3 COMPARATIVE VALUES FOR TWIN ENGINES ($\beta_0/\beta_x = 1.09$)

ASSUMED SPECIFICATIONS

Type of engine......	Twin-cylinder double-acting two-stroke gas engine with tail rod
Cylinder dimensions.....	38 x 66 in.; speed, 80 r.p.m.
Piston-rod diameter.......	10 in.
Assumed load....................	4000 b.hp. = max. capacity
Moment of inertia of wheel.......	$\frac{113{,}000\text{ lb.}}{32} \times 9.65\text{ ft.}^2$
Total mass m.....	43,500 units at R = 2.75 ft.
K' by differential method	0.072
P_0 from crank-effort curve........	48,000 lb. = 0.48 P_c
Lead angle α_0	about 16½° = 0.29 elec. radian
n...........................	20 pole pairs
β_0'..........................	0.105 N = 8.4

RESULTS

	Calculated by Formulæ	Graphical Determinations
$(2/\pi)\ r_0'$ when K' = 0.072.	0.02 ft. per sec.	0.026 ft. per sec.
$(2/\pi)\ s_0'$ when K' = 0.072.........	0.0027 ft.	0.0022 ft.
β_x by Eq. [18a]..................	7.7 = $\beta_0'/1.09$	....
$\pi/(\beta_0' - \beta_x)$ by Eq. [24]..........	4½ sec. = 6 rev.	about 5½ rev.
Angle α_x' by Eq. [25]............	0.96 α_0	About 0.85 α_0
Angle α_{xav}' by Eq. [26]...........	0.37 α_0	....
Displacement shift s_x'............	About 9 s_0'	About 8 s_0'
$2\pi/(\beta_0' + \beta_x)$................	0.39 sec.	0.39 sec.

CONCLUSIONS

On the basis of the principles enunciated, it may be concluded that when two alternators are thrown into parallel the resulting cross-current flow, as measured by means of ammeters, will be largely independent of the wheel weight used, except in so far as this weight may influence the character of the regulation rendered by the governor.

The difficulty that may be involved in the use of a light flywheel resides in the detrimental secondary effects that may arise. When the ratio of β_0/β_x is less than 7/2, as is likely to be the case when using a light wheel, the oscillatory peak movement indicated in Fig. 5 becomes about twice as large as would be produced by the use of a heavy wheel operating under conditions represented by Fig. 4. This difference in maximum angular displacement shift may become so marked that the armature working with a relatively light wheel may be thrown far over into the negative or motor position. Such excessive shift in the armature displacement may readily create serious electrical disturbance, for should the angle α_x' plus α_0 at any time exceed $\pi/2$ electrical radians, i.e., one-half pole pitch, the paralleled generators would immediately fall out of step.

The best results in parallel operation may, therefore, be expected when the ratio β_0/β_x is kept as high as 6 or possibly 8. As is evident from Eq. [18] and [18a], this condition is more readily complied with in the smaller short-stroke engines running at a relatively high speed. However, in order to avoid excessively heavy wheels for the long-stroke, slow-speed engines, it is found advisable to keep the wheel weight in a constant relation to the engine output.

The foregoing deductions do not take into account any beneficial effects which dampening coils and like devices may be able to exert upon the cumulative armature oscillations. The purpose of the present investigation was simply to find

the most favorable inherent conditions when operating without compensating adjuncts of any kind.

The formulæ given are further conditioned upon identical constructive characteristics for all the paralleled engine and generator units. Any important difference in this respect may involve a considerable increase in the minimum expected cross-current flow as fixed by the given formulæ.

Finally, attention is called to the need of properly selecting the coefficient of speed fluctuation for the engine governor. The extent to which the primary speed coefficient may be increased by the cumulative displacements arising in paralleled engine units is indicated by the ratio of s_1/s_0 as given in Tables 2 and 3. The governor characteristics should be such that this increased "factor of irregularity" will not throw the governor gear into resonant oscillation with the cumulative wheel period.

The use of additional wheel weight is able to effect an important change in the period of the cumulative wheel swing, and this, in turn, may make it far easier to meet the governing requirements. On the whole, therefore, it may be concluded that owing to the beneficial secondary effects the most satisfactory results in the parallel operation of reciprocating-engine units are to be attained by the use of reasonably heavy flywheels, as prescribed.

The author desires to express his indebtedness to Prof. C. D. Albert, of Cornell University, for reviewing the manuscript of this paper and for the helpful criticisms which he has made.

In marked contrast with the ordinary formal official report, the chapter on fuels and mechanical-equipment investigations in the year book of the Bureau of Mines (Department of the Interior) is of readable interest and practicable value to all concerned in fuel economy and conservation. It is stated that last year 500,000,000 tons of coal was burned, but of this amount the bureau estimates fully 125,000,000 tons, or 25 per cent. was wasted through incomplete combustion and other preventable waste. The function of the Bureau of Mines and the results obtained through its extensive investigations are also set forth in the publication.

A cobalt-chrome-carbon steel is now being made by a Sheffield works, for which it is stated that the property of red-hardness is obtained without the addition of tungsten. This steel is said to melt at lower temperatures than tungsten high-speed steel, and to be so fluid as to be readily cast into intricate forms for milling cutters, gages and similar products. It may also be annealed in the usual manner to a sufficient degree of softness to be readily machined, and can be forged without difficulty. It can be hardened by heating to 1000 deg. cent. and cooling in still air without an air blast.—*The Ironmonger*, August 11, 1917.

Before means can be found to reduce smoke, it is obvious that the causes of its production must be understood. The erroneous opinion prevails that black smoke contains a large amount of combustible matter and that it is a sign of greatly reduced economy. The most dense black smoke does not commonly contain more than ½ of 1 per cent of the combustible fired. The extreme fineness and the distribution of the carbon particles bestow upon them a high coloring power. The losses are negligible in comparison with those due to incomplete combustion or excessive air, which generally accompany combustion without visible smoke. The carbon particles producing visible smoke are not derived from a lifting of fixed or solid carbon from the grates, but they are formed from gases during the combustion process.—*Power*, September 18, 1917.

The War Convention of American Business, brought together at the call of the Chamber of Commerce of the United States, met at Atlantic City, September 17 to 21. The chief topic of discussion was the regulation and control of prices by the Government, the organization of war production, and the adjustment of business during and after the war. Suggestions were made that a war board should be created, similar to the Ministry of Munitions in England, which would control purchases for the Government, determine prices and control priority in distribution in order to do away with the competition between Government demands and those of private industry, which at present is working considerable hardship on business men over the country.

Among the educational institutions which have been patriotically devoting the summer recess to the intensive training of enlisted men should be mentioned Wentworth Institute. The institute has been giving such training to the men of the 101st Massachusetts Engineers, who have received quite a comprehensive outline of the essentials of machine-shop operations, steam engines, pumps, electrical construction and steam and electrical power-plant practice. An enormous amount of practical work has been accomplished and the thorough manner in which these young engineers have constructed a long series of trenches, bomb-proof shelters of reinforced concrete, dug-outs, etc., with all of the latest devices, emergency exits, drainage provisions, wire entanglements, suspension and pontoon bridges, electrical generating stations for use in the field to supply power, light and telephone and telegraph facilities for field operations, ensures their early participation in the actual operations in the field.

The present national crisis brings home to us the crying needs of the nation in availing itself of the knowledge and ability at its command. Fifty thousand specialists in applying scientific knowledge to practical problems as well as scores of research laboratories have offered their services to the nation. But problems requiring investigation are slow in being developed. Once they are formulated and given to the engineers of the country, few will remain unsolved very long.

It is for the engineer to apply the results of research to practical problems and to carry practical problems demanding general research back to the research laboratories. To the engineer, every special problem requires a special application of fundamental principles. Is it too much to hope that the day is rapidly approaching when all great problems, particularly those of our national and state governments, will be automatically placed in the hands of trained specialists? Not self-seeking politicians, nor yet men with mere theories, but engineers with a real command of fundamental principles, men with an unbroken record of big achievements and no failures, men ever ready to stake their all on their ability to handle problems in their specialty.—*Science*, September 14, 1917.

THE TRANSFER OF HEAT BETWEEN A FLOWING GAS AND A CONTAINING FLUE

By LAWFORD H. FRY, BURNHAM, PA.

Member of the Society

THE transfer of heat between a flowing gas and the wall of a metallic flue through which the gas flows is one of the most important processes in mechanical engineering, and as such has been the subject of much study by physicists and by engineers. All attempts, however, to bring the process under the yoke of a general formula have been very imperfectly successful.

The author now offers the formula described below, which within a wide range of conditions will represent with all the accuracy needed for practical work the processes of heat transfer between a gas and a metallic flue wall.

The formula applies equally well to the loss of heat by a hot gas in a cooler flue and to the gain of heat by a cool gas in a hotter flue, and although it has been established by purely empiric methods, yet the accuracy with which it conforms to the results obtained by various observers using widely differing experimental methods leads to the belief that it represents closely the fundamental law by which heat is transferred under the conditions under consideration.

The wide range of the experimental data on which the formula is based is shown in Table 1 and may be summarized briefly as follows:

Gases. The gases experimented with were products of combustion, lighting gas, CO_2 and air, all at atmospheric pressure; also air at pressures ranging from 0.15 to 140 lb. per sq. in. abs.

Rate of Flow of Gas. The rates of flow ranged from 0.5 to 650 lb. per hr.

Flues. Flues of annular and circular cross-section were used, with effective diameters ranging from 0.5 to 2.0 in., and of lengths from 0.64 to 20 ft.

Temperatures. The inlet gas temperatures ranged from 2340 deg. fahr. with the products of combustion being cooled, to 55 deg. fahr. with air being warmed.

In all of the experiments throughout this wide range of conditions the transfer of heat is satisfactorily represented by the general formula proposed below.

GENERAL FORMULA FOR HEAT TRANSFER

The type of formula used is adapted from that suggested by Fessenden and Hedrick.[1] No attempt is made to measure the rate of heat transfer per square foot of heating surface per degree of temperature difference, but an expression is given for the rise or fall in temperature of a gas in its passage along a flue the wall of which is at a higher or a lower temperature than the gas.

If a gas flows at the rate of W lb. per hour through a flue of which the hydraulic depth is $d/4$ in. (in a flue of circular section the diameter corresponding to this hydraulic depth is d in.), and if the temperature of the gas be T_1 deg. in any given section and T_2 deg. in a section x ft. distant in the direction of the flow, and if the mean flue temperature between these two sections be t deg., all temperatures being measured from the absolute zero in any scale; then, if the gas temperature be higher than the flue temperature,

$$^{2}\text{lolog } T_1/t - \text{lolog } T_2/t = Mx \ldots\ldots\ldots [1]$$

and if the flue temperature be higher than the gas temperature,

$$\text{lolog } t/T_1 - \text{lolog } t/T_2 = Mx \ldots\ldots\ldots [1a]$$

where M is a constant in any given case, being dependent only on W the rate of flow of the gas, and on $d/4$ the hydraulic depth of the flue. In the experiments under consideration there is a critical rate of flow at about 5 lb. of gas per hr. At all rates of flow above this the value of the coefficient M is accurately given by the equations

$$\text{Log } M = A - m \log W \ldots\ldots\ldots [2]$$

where

$$A = 1.558 - 0.185d \ldots\ldots\ldots [3]$$

and

$$m = 0.14 + 0.083d \ldots\ldots\ldots [4]$$

The application of Equation [1] is illustrated by Figs. 1, 2 and 3, which are based on one of the Babcock and Wilcox experiments in which products of combustion at a high temperature were passed through a water-jacketed flue and the temperature determined at a number of points along the flue.

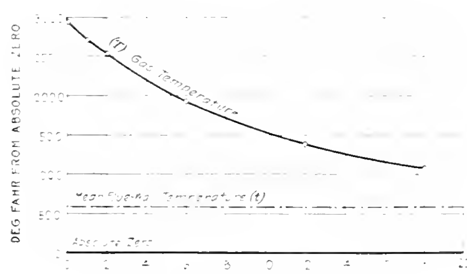

FIG. 1 MEAN GAS TEMPERATURES AND MEAN FLUE TEMPERATURE

(B. & W. Test 1, April 13.)

The abscissæ in all three figures are distances in feet from the furnace end of the flue. In Fig. 1 the ordinates of the curve are the gas temperatures T in degrees fahrenheit above the absolute zero. A horizontal line is also drawn having as ordinates the mean flue-wall temperature t.

In Fig. 2 the ordinates are the logarithms of the ratio of gas temperature to mean flue temperature, $\log T/t$, while in Fig. 3 the ordinates are the logarithms of the ordinates in Fig. 2, that is, they are the logarithms of the logarithms of the temperature ratios, [log (log T/t) or lolog T/t]. In Fig. 3 the points plotted fall on a straight line and it is obvious that if

[1] Trans. Am.Soc.M.E., vol. 38, p. 407.

[2] Chappell's very convenient logarithmic notation is used, by which "lolog N" denotes "the logarithm of the logarithm of the number N," all logarithms being to the base 10. (Five Figure Mathematical Tables, by E. Chappell.)

For presentation at the Annual Meeting, December 4 to 7, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Pamphlet copies of the paper may be obtained gratis upon application. All papers are subject to revision.

T_1 be the gas temperature at any point and T the gas temperature at a point x ft. further along the flue the relation between the two temperatures is given by the equation

$$\text{lolog } T_1/t - \text{lolog } T/t = Mx \quad \ldots\ldots\ldots [1]$$

where M is the slope of the line.

The purpose of the present paper is (1) to show that this relation is a general one, and (2) to show how M, the coefficient measuring the slope of the lolog line, is affected by the rate of flow of the gas and by the flue diameter. It should be noted that the coefficient M is dependent not on the actual diameter of the flue but on the hydraulic depth, that is, on the quotient of the area divided by the perimeter. In the case of a flue of circular cross-section the hydraulic depth is one-quarter the diameter, and it is immaterial whether diameter or hydraulic depth be taken as argument in establishing the relationship with the coefficient M. As most of the present work concerns circular flues, it is convenient to use the "effective diameter" d in determining the relation between flue section

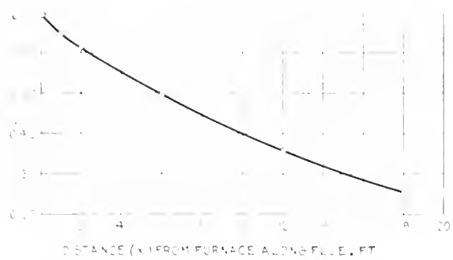

Fig. 2 Logarithm of Ratio of Gas Temperature to Flue Temperature

(B. & W. Test 1, April 13.)

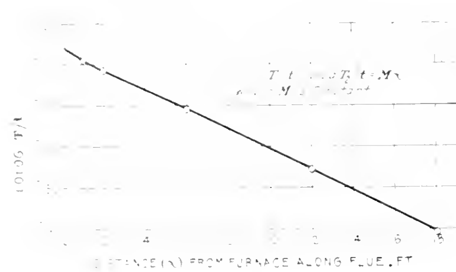

Fig. 3 Logarithm of Logarithm of Temperature Ratio

(B. & W. Test 1, April 13.)

and the coefficient M. This "effective diameter," being defined as four times the hydraulic depth, is the same as the actual diameter in a flue of circular cross-section. Examination of the experimental data has led to the conclusion that the relation between the coefficient M, the rate of flow of gas W, and the effective flue diameter d, is that shown above in Equations [2], [3] and [4].

EXPERIMENTAL DATA

The data on which the conclusions stated above are based have been derived from a total of 205 experiments, the range of conditions covered by them being shown in Table 1. These experiments fall into six groups, each of which is due to a different experimenter. The Jordan[3] experiments are among the most accurate, and as they cover a wide range of flue diameters, have played a considerable part in establishing the formulæ. They comprise five series, each with a flue of a different section. Two of the flues were annular and three circular in section, the effective diameter ranging from 0.506 to 1.968 in. The gas used was air, the rate of flow ranging from 30 to 620 lb. per hr. and the inlet temperature from 238 to 750 deg. fahr. The air was passed through a vertical flue 3.28 ft. long, surrounded by cooling water flowing in the opposite direction to the air. Inlet and outlet temperatures of the air were measured.

The Nusselt[4] experiments were made with air at a pressure of 140 lb. per sq. in., and with air, CO_2 and lighting gas at atmospheric pressure. These gases at atmospheric temperatures were passed through a horizontal flue 0.868 in. in diameter surrounded by steam at atmospheric pressure, and the rise in temperature measured. The length of flue in which the temperature rise took place varied from 0.64 to 1.96 ft. The rate of flow of gas varied from 1 to 400 lb. per hr. These experiments were carried out with great care and are valuable on account of the wide range of rate of gas flow, and because gases of various compositions were used. The Josse[5] experiments, like those of Nusselt, were made with a horizontal steam-jacketed flue, through which air at atmospheric temperature was passed and the rise in temperature measured. Pressures of 1.5, 7.5 and 15 lb. per sq. in. were used, the rate of flow ranging from 0.5 to 71 lb. per hr. The flue was 0.905 in. in diameter and 4.34 ft. long. The Babcock and Wilcox[6] experiments considered here are seven in number, taken at random from an elaborate series in which the products of combustion from a gas furnace were passed through a water-jacketed flue 2 in. in diameter and 20 ft. long. The gas inlet temperatures ranged from 1750 to 2350 deg. fahr., and as the water jacket was divided into twenty compartments each one foot long, the drop in temperature of the gas along the flue could be determined by measuring the amount of heat absorbed in each compartment of the jacket. The mean water temperature was approximately 160 deg. fahr. The Fessenden[7] experiments were very similar to the Babcock and Wilcox, but in one series a flue 1.816 in. in diameter and 10.95 ft. long, and in the other series a flue 0.816 in. in diameter and 10.44 ft. long, was used. In both series the jacket was divided into ten compartments in which water was allowed to boil at atmospheric pressure. Inlet and outlet temperatures were measured, and the drop of temperature along the flue could be found by measuring the amount of heat given up to each compartment of the jacket. The Pennsylvania Railroad[8] experiments are taken from tests of locomotives on the Altoona locomotive testing plant. One boiler had flues 2 in. in diameter and 18.75 ft. long, the other had flues 1.75 in. in diameter and 15 ft. long. The firebox and smokebox temperatures were measured in each experiment and the weight of the products of combustion determined from the flue-gas analysis.

DERIVATION OF FORMULÆ FROM EXPERIMENTAL DATA

The process of studying the validity of Equation [1] and of arriving at the law expressed by Equations [2], [3] and [4] is illustrated by Figs. 4 to 7.

The first step was to calculate from the figures obtained experimentally the value of the coefficient M in Equation [1]. This having been done and the results tabulated, it became evi-

[8] Locomotive Tests and Exhibits; The Pennsylvania R. R. System, 1905. Tests of an E2A Locomotive; Locomotive Testing Plant Bulletin No. 5; Pennsylvania R. R. Co., 1910.

dent that in each series of experiments made with the same diameter flue the values of M decreased regularly as the rate of gas flow increased. In the search for the law governing this change the values of log M were plotted as ordinates over the values of log W as abscissæ, (W = lb. of gas per hr.). Fig. 5 showing the results obtained from Nusselt's experiments is typical and is of interest as covering the widest range of gas-flow rates and as covering gases of three different compositions and of widely different pressures. From this plot it appears that there is a critical rate of flow at about 5 lb. of gas per hr., $W = 5$, log $W = 0.699$, and that for rates of flow greater than this the relation between log M and log W is a well-marked straight line of the form log $M = A - m$ log W (Eq. [2]).

Before examining the numerical values of the coefficients in this equation, attention will be directed to the meaning of the two formulæ which have been set up. In Fig. 6, which is Fig. 5 redrawn in diagram form, AB represents the lolog of the temperature ratio at a given cross-section of the flue and CD the lolog of the temperature ratio at a section x ft. further along the flue. Then the slope of the line AC is determined by the value of the coefficient M. If the coefficient has a larger value, say M', the line will have a sharper slope and the value of lolog t T_2 will be $C'D$, which is less than before. This means that the temperature T_2 will be greater than before. An increase in the value of the coefficient M corresponds to a more rapid interchange of heat between flue wall and gas, and consequently in the case under consideration, to a greater increase in the temperature of the gas.

The influence of the rate of gas flow on the coefficient M in any given flue is well illustrated by Fig. 5. As the rate of flow is increased the value of the coefficient M decreases, that is to say, the amount of change in the temperature of the gas between any two points decreases. For example, in Fig. 5 the line drawn through the plotted points of the Nusselt experiments shows the following values for log W and log M:

log W =	1.0	1.505	2.00	2.70
log M =	$\bar{1}.123$	1.017	$\bar{2}.905$	$\bar{2}.755$

From which the following values are found for W and M:

W =	10	32	100	500
M =	0.1328	0.1040	0.08036	0.05689

If an initial gas temperature of 70 deg. fahr. be assumed, the temperature of the gas after passing 1 ft. along the flue which is maintained at 212 deg. fahr. will vary as follows:

Rate of flow, lb. per hr., W =	10	32	100	500
Temperature, deg. fahr. T_2 =	105.5	98.5	92.5	86.0
Rise in temperature, $T_2 - T_1$ =	35.5	28.5	22.5	16.0

The rise in temperature becomes less and less as the rate of flow is increased. If the amount of heat transferred to the gas is calculated from the foregoing, assuming a specific heat of 0.238, the following figures are obtained:

Rate of flow, lb. per hr. .... W =	10	32	100	500
Heat transfer, B.t.u. per hr.. $0.238\ W(T_2 - T_1)$ =	84.6	217	536	1910

From this it will be seen that when flowing at the rate of 10 lb. per hr. the temperature of the gas is raised 35.5 deg. out of a possible 42 deg., the transfer of heat being at the rate of 84.6 B.t.u. per hr., while if the rate of flow is increased to 500 lb. per hr. the temperature rise is only 16 deg., but the heat is transferred at the rate of 1910 B.t.u. per hr.

NUMERICAL VALUES FOR COEFFICIENTS

Returning to Equations [1] and [2] in order to evaluate the coefficients, Figs. 4 to 8 come under observation. The process adopted in deciding on the values given in Equations [3] and [4] was to plot on a fairly large scale values of log M as ordinates against values of log W as abscissæ. This having been done for the five Jordan series, for the Nusselt and for the Babcock and Wilcox groups of experiments, all of which can lay claim to a high degree of accuracy, it was evident that Equation [2], or log $M = A - m$ log W, was universally applicable if the coefficients A and m were properly chosen to suit each flue. This is made clear by Fig. 4, in which all of the seven series just referred to are brought together in one plot. It is evident from this that the coefficients A and m which determine the position of the lines in this plot depend on the ef-

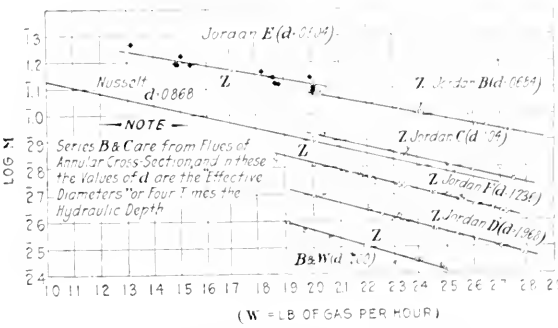

Fig. 4 Relation Between Coefficient M and Rate of Flow of Gas for Various Flue Diameters

All lines are represented by the equation

$$\log M = \bar{1}.87 - (2.23 + \log W)\, m,$$

which may be written log $M = A - m$ log W, where $A = \bar{1}.87 - 2.23\ m$. This indicates that all of the lines if extended will pass through the point at which log $M = \bar{1}.87$ and log $W = -2.23 = \bar{3}.77$.

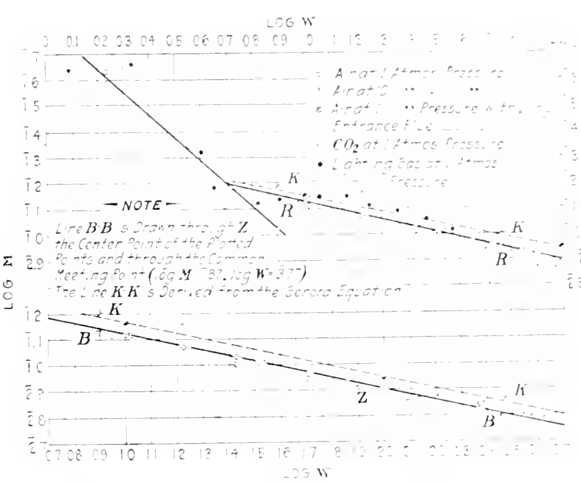

Fig. 5 Relation Between Coefficient M and Rate of Gas Flow from Nusselt's Experiments with Various Gases

fective diameter of the flue. The problem is then narrowed down to the selection of values for these coefficients which shall be in some regular relation to the effective flue diameter, and which shall at the same time harmonize with the individual points derived from the experiments.

In studying this problem it was found that in each series of experiments the points plotted in Fig. 4 could be closely represented by a group of straight lines and all the lines thus obtained passed through point (log $M = \bar{1}.87$, log $W = \bar{3}.87$). In other words, the points representing the relation between log M and log W for all the experiments in the seven series now under consideration lie on a series of straight lines radiating

from the common point ($\log M = \overline{1}.87$, $\log W = \overline{3}.77$). Having discovered this property, the positions of the lines shown in Fig. 4 were established by choosing for each series of experiments a center point (these are the points marked Z in Fig. 1) and drawing lines through the common meeting point and through these center points.

Table 2 shows in columns 3 and 4 the coördinates of the center points selected for each series, and in columns 5 and 6 the values of the coefficients A and m for each of the lines passing through these center points and through the common meeting point. To connect these coefficients with the effective flue diameter they are plotted as ordinates in Fig. 7 over the flue

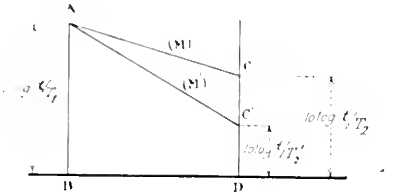

FIG. 6 DIAGRAM SHOWING EFFECT OF A CHANGE IN THE VALUE OF THE COEFFICIENT M

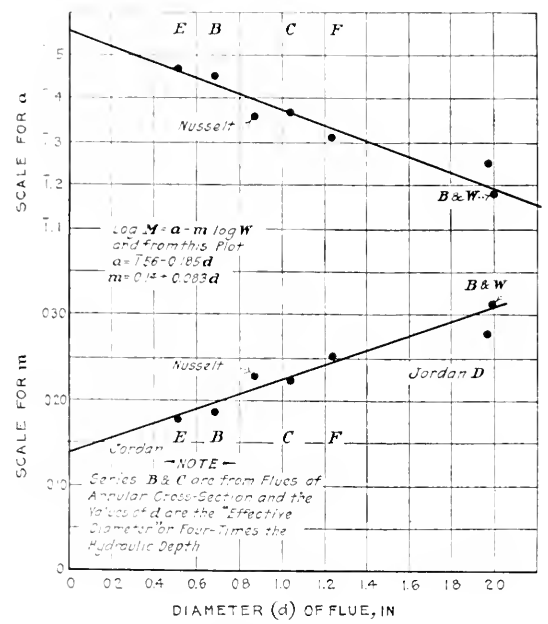

FIG. 7 RELATION BETWEEN FLUE DIAMETER AND COEFFICIENTS m AND A IN THE EQUATION LOG $M = A - m$ LOG W

The value of m being determined by the line drawn through the plotted values of m, the value of A follows from the equation $A = \overline{1}.87 - 2.23\ m$.

diameters d as abscissæ. All of the points lie fairly close to a straight line, and for the coefficient m a line with the equation $m = 0.14 + 0.083d$, or Eq. [4], was chosen as representing most satisfactorily the relation between m and d. Now since all of the lines in Fig. 5 are drawn to pass through the point ($\log M = \overline{1}.87$, $\log W = \overline{3}.77$), they can all be represented by the equation

$$\log M = \overline{1}.87 - (\log W - \overline{3}.77)\ m \quad \ldots\ldots [5]$$

which can be written

$$\log M = \overline{1}.87 - (2.23 + \log W)\ m \quad \ldots\ldots [5a]$$

since $\overline{3}.77 = -2.23$, or by regrouping,

$$\log M = (\overline{1}.87 - 2.23\ m) - m \log W \quad \ldots\ldots [5b]$$

Combining this with Equation [2], it follows that

$$A = \overline{1}.87 - 2.23\ m \quad \ldots\ldots [6]$$

and giving m the value found above in Equation [4], Equation [6] becomes

$$A = \overline{1}.56 - 0.185\ d \quad \ldots\ldots [3]$$

This completes the account of the development of the formulæ proposed. It now remains to consider their application to other independent experiments and to consider critically some portion of the work described above.

APPLICATION OF THE FORMULÆ TO OTHER EXPERIMENTS

In addition to those from the seven series of experiments considered above, experimental data from five other series are available for comparison. These are the two series by Fessenden, one by Josse, and two series of the Pennsylvania Railroad locomotive tests. For these experiments values of M were calculated as before and the values of $\log M$ plotted against $\log W$ in Figs. 8 to 11. In these figures the points are rather more scattered than in those previously considered, and the straight-line relation between $\log M$ and $\log W$ is not so clearly marked. This is probably due to a somewhat lower degree of accuracy in the experiments, and it was for this reason that these series were used for checking rather than for establishing the formulæ. The value of the coefficients A and m as determined by Equations [3] and [4] for the respective flue diameters are given for all twelve series of experiments in columns 7 and 8 of Table 2. The lines corresponding to these coefficients are drawn in in the various figures and marked K-K. In the Josse experiments, Fig. 8, the values of M given by the line K-K derived from Equations [2], [3] and [4] are slightly higher than those calculated from the experiments. The deviation of the line from the points is hardly greater than the discrepancies between the individual points. In view of the fact that no very elaborate precautions were taken to prevent errors in these experiments, it is quite probable that the formula represents the actual conditions at least as closely as do the figures derived from the experimental data. This series is also interesting, as it confirms the indication given by the Nusselt experiments of a critical gas speed at about 5 lb. per hr., $\log W = 0.699$. In the Fessenden experiments the points in Series I, Fig. 9, are very smoothly grouped and could hardly be better represented than they are by the line K-K given by the formulæ. In Series II, Fig. 10, the agreement between the calculated line K-K and the experimentally derived points is apparently not so close, but in this case the experimental conditions were such as to give a comparatively large variation in the coefficient M for a small variation in the heat absorption. In Fig. 10, for a rate of gas flow of 19.7 lb. of gas per hr., that is, $\log W = 1.295$, the value of $\log M$ from the formulæ as shown by the line K-K is $\overline{1}.15$, while the experimental points show $\log M = \overline{1}.05$. The experimental conditions corresponding to this rate of flow of gas show a temperature drop from 2003 deg. fahr. to 281 deg. fahr. in a flue 10.44 ft. long. The use of the calculated value of the coefficient M would change the outlet temperature from 281 to 238 deg. fahr., making the temperature drop 1765 instead of 1722 deg. This only means a difference of 2.5 per cent in the amount of heat absorbed from the gas, which is within the range of errors of observation in these experiments. There is therefore no real conflict between the experimental data and the formulæ proposed. The Pennsylvania Railroad locomotive tests, Fig. 11, show remarkably close agreement between the points derived from the experiments and the lines K-K given by the formulæ. A noticeable feature in this figure is the difference shown by the experiments in the value of the coefficient M in the two series of

CONCLUSIONS

firmed as to accuracy of results by the five series of Fessenden, Josse, and Pennsylvania Railroad experiments.

A DIAGRAMMATIC METHOD OF CONSIDERING THE PROCESS OF HEAT TRANSFER

Mechanism of Heat Transfer. In considering the problems connected with the transfer of heat between gas and flue wall, it is desirable to form some sort of mental picture of the physical processes which are in action. Fig. 12 is a diagram offered as a means to this end.

The gas is imagined to flow from left to right through the flue indicated in Fig. 12, while the dotted diagonal lines are intended to represent, in a very much simplified way, the path of individual particles of gas. Starting from a point in the center of the flue with a temperature of say T_{c_1}, a particle travels outwards and forwards until it impinges on the flue wall. For an instant the particle will flatten itself so to speak against the wall, and in this intimate contact will take on the temperature of the wall (T_w). It will then rebound at this temperature. During the rebound other particles approaching the flue wall will be encountered and there will be an interchange of heat and consequently of temperature, so that the temperature of the particles approaching the wall tends to approach the wall temperature before actual contact, while the particles leaving the wall tend to recover the center temperature T_{c_1}. As a consequence, when the particle first taken under consideration again reaches the center of the flue it will have a temperature T_{c_2}, which is higher or lower than T_{c_1} according as the wall temperature is higher or lower than the gas temperature. The process is repeated and on again

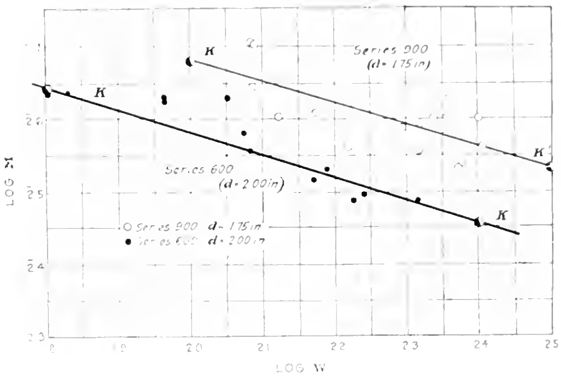

FIG. 11 RELATION BETWEEN COEFFICIENT M AND RATE OF GAS FLOW FROM PENNSYLVANIA RAILROAD LOCOMOTIVE TESTS

(Line K-K derived from the general formula.)

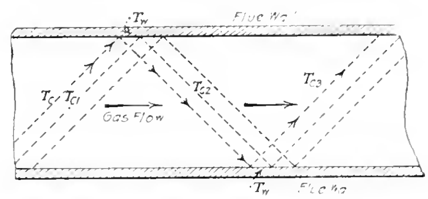

FIG. 12 DIAGRAM REPRESENTING PATH OF GAS PARTICLES AND TRANSFER OF HEAT

reaching the center the particle will have the temperature T_{c_3} and so on. This simplified way of looking at the heat-transfer process will give a correct understanding of the so-called film of dead gas supposed to adhere to the flue and to be scrubbed off to permit a more rapid rate of transfer when rate of flow of gas is increased. The particles, as has been said, are in contact with the flue wall for an instant and come away at the wall temperature, so that there is in effect a film of gas at the wall temperature close to the flue. This will to a certain extent protect the flue wall and cushion it against the particles coming from the center, but if the center particles do not strike the wall they impinge on the wall particles and effect an interchange of heat with these, some of which travel again to the wall, thus continuing exchange of heat between wall and gas.

If the amount of gas passing through the flue be increased heat is transferred between gas and flue at a faster rate, but this is not because the film of gas at wall temperature is swept off the flue wall, but because more particles are introduced to

bombard each unit of wall space. It must be remembered that while an increase in the rate of gas flow increases the rate of heat transmission, it at the same time reduces the efficiency of the process. This has already been dealt with, but in view of much that has been written on this subject, by Nicolson[9] among others, the point is worth emphasizing. Take the case of a boiler flue in which hot products of combustion are being cooled. A certain rate of flow gives a certain temperature drop and a certain amount of heat absorbed. If the rate of flow be doubled it will be found that the temperature drop is less than before; that is, the amount of heat absorbed from each pound of gas is less—the efficiency of the flue in absorbing heat has been reduced. Since, however, the weight of gas has been doubled while the amount of heat absorbed from each pound has not been halved, the total amount of heat absorbed is greater, that is, the effectiveness of the flue in absorbing heat has been increased. It would seem as though with the increase of gas flow there was an interference between the particles in their bombardment of the flue wall; although the number of hits is doubled the blows interfere with each other and are not so direct, with the result that though the amount of heat transferred is increased it is not doubled. In many cases advocates of high rates of gas flow fail to distinguish between effectiveness and efficiency.

The bombardment of the flue wall by the gas particles also serves to explain the effect of hydraulic depth on heat transmission. The hydraulic depth may be decreased either by reducing the diameter of the flue or by inserting a core so as to reduce the cross-sectional area while maintaining the perimeter (hydraulic depth = area perimeter). With a reduced hydraulic depth the particles have a shorter distance to travel between center and wall, and consequently the same number of particles will make a greater number of hits in the same time and they will therefore effect the transfer of a larger amount of heat.

Gas Temperature. In setting out the various formulæ for change of temperature along the length of the flue, the temperature of the gas at various points along the flue has been spoken of. This was done with the understanding that the "temperature of the gas" in this sense is a term needing careful definition. In any section of the flue perpendicular to the longitudinal axis the temperature will vary from center to wall. The gas therefore has no definite temperature at that section, but the term "gas temperature" as used in the paper is to be understood as meaning the mean temperature of the gas crossing the section under consideration, that is, the temperature at which the gas if uniformly heated would carry past the section the same amount of heat as is actually carried. This temperature cannot be measured directly by a mercury thermometer or by a thermocouple. Nusselt measured the mean temperature, apparently with a fair degree of success, by means of a resistance thermometer formed of a spiral of wire wound on a mica cross in such a way as to traverse practically the whole sectional area of the flue. In this connection he points out that with pyrometers or bulb thermometers the radiation effect between instrument and flue wall will prevent accuracy of measurement.

Heat Transfer and Loss of Head. On considering the action of heat transfer as outlined above it will be apparent that there must be an intimate relation between the rate of heat transfer and the loss of head by the gas. As each particle impinges on the flue wall it loses (or gains) a certain proportion of its heat, and at the same time must, unless the flue wall be perfectly smooth—which is of course physically impossible, lose some of its velocity in the direction of the longitudinal axis of the flue.

Nusselt pointed out that Osborne and Stanton have dealt with this phase of the question mathematically, and Stuart[10] in discussing the performance of coolers for lubricating oil says that in the case of the oil and of the water flowing through the coolers the relative friction drops are of the same order as the relative heat-transfer factors.

The laws governing the loss of head by a fluid passing through a flue are still but imperfectly established, and it is suggested that a formula of the type given in the paper for heat transfer might be worked out to serve as a general formula for loss of head.

Such a general formula would be valuable, as loss of heat represents the price that must be paid for heat transfer. In any attempt to increase the rate of heat transfer by increasing the rate of flow of the gas, the limit is set by the loss of head. Beyond a certain point the loss of head, or in other words the amount of energy required to drive the gas through the flue, makes the gain in heat transfer unremunerative.

A STUDY OF SURFACE RESISTANCE WITH GLASS AS THE TRANSMISSION MEDIUM

By H. R. Hammond[1] and C. W. Holmberg,[2] Brooklyn, N. Y.

In the study of heat transmission the determinations of the thermal resistances of material have been obtained in a more or less vague manner. At present the majority of coefficients used are combined coefficients; that is, no attempt is made at discriminating between the conduction of the material itself and the conductions of the two air spaces which exist adjacent to it. Consequently there are no standards by which surface resistance may be obtained. A method has been used by which the temperatures of the air, both outside and inside, were measured at a distance of 1 in. from the surface, but this has never been verified.

In an attempt to obtain some data on the subject of surface resistance with glass as the transmission medium, this paper will deal with the following points:

1 A study of the temperature gradients under various temperature differences between the inside and outside of the box

2 The relative values of conduction for the glass and for the air surfaces

[1] 256 Jefferson Ave.
[2] 354 Senator St.

For presentation at the Annual Meeting of The American Society of Mechanical Engineers, New York, December 4 to 7, 1917. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

3 The variation of the conduction values under the various temperature differences between the inside and the outside of the box.

THEORY

Heat may be transmitted from one side of a wall to the other in three ways: by radiation, by convection, and by conduction. In this paper, however, the radiation and convection factors will not be dealt with, and the formulæ which follow have to do only with conduction.

For total heat transmitted, we may write:

$$Q = kA(\Delta T) \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

where Q = total B.t.u. transmitted per hour

k = transmission in B.t.u. per hour per sq. ft. per deg. difference in temperature

A = area of the surface in sq. ft.

(ΔT) = temperature difference, deg. fahr.

The value of k depends upon several factors: the surfaces, the thickness and kind of material, air spaces, absolute temperature, temperature difference, and condition of air at the surfaces. The combined transmission coefficient of a com-

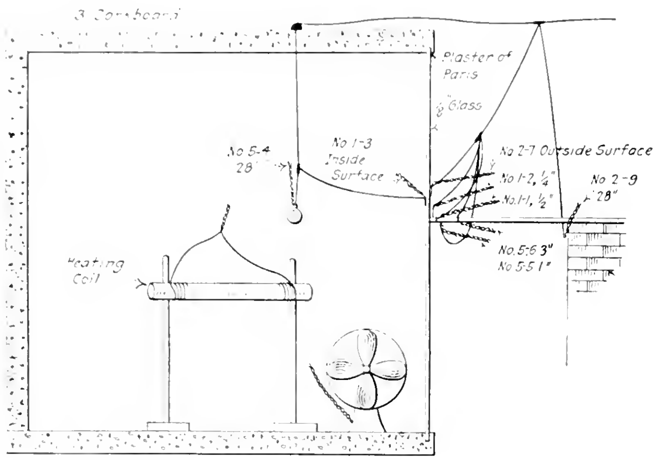

FIG. 1 APPARATUS FOR DETERMINING TEMPERATURE GRADIENT

pound wall is determined from the sums of the reciprocals of the various conduction coefficients, as follows:

$$k = \frac{1}{C_1} + \frac{x_2}{C_2} + \frac{x_3}{C_3} \cdots\cdots \frac{x_n}{C_n} + \frac{1}{C_{n_1}} \ldots\ldots\ldots [2]$$

where C_1 = conduction of inside air surface in B.t.u. per hr. per sq. ft. per deg. difference in temperature

$C_2, C_3, \ldots C_n$ = conduction of material per hr. per unit thickness per sq. ft. per deg. difference in temperature

C_{n_1} = conduction of outside air surface in B.t.u. per hr. per sq. ft. per deg. difference in temperature

$x_2, x_3, \ldots x_n$ = thickness of material in inches.

PROCEDURE

The experiments were carried on in the thermal testing plant of the Pennsylvania State College, which consists of a room 17 x 17 x 10 ft., well insulated with corkboard and kept at a constant temperature by means of brine coils placed around the wall. Bulletin No. 9, Vol. 1, published by the Pennsylvania State College Experiment Station, contains illustrations and a complete description of this plant.

The experiments were made with a corkboard box (Fig. 1) 5 ft. by 5 ft. by 5 ft. 1 in. in outside dimensions and having a mean surface area of 141 sq. ft. The temperatures were recorded by platinum-resistance thermometers made by the Leeds & Northrup Co. and specially designed for this plant. Carefully calibrated voltmeters and ammeters were used to measure the heat input to the box.

Before proceeding with the tests the resistance thermometers and the box were carefully calibrated. The thermometers were calibrated by comparison with a standard mercury thermometer reading to 0.2 deg. and estimated to 0.01 deg. The thermometers were placed in a small box to protect them from any air currents that might affect the readings. The readings on the mercury thermometer were taken through a telescope in order that they might be estimated more accurately and not be affected by heat radiation from the person taking them. The resistance-thermometer readings were indicated by the usual Wheatstone bridge as supplied by Leeds & Northrup Co. Readings were taken of the various thermometers every ten minutes, and after a series of tests under different temperatures, the calibration curves were plotted.

In calibrating the corkboard box for different ranges of temperatures from inside to outside, a thermometer was suspended midway between the top and bottom and 10 in. from the inside surface, and another placed outside in the room. The room was kept at a constant temperature by means of brine circulating through coils around the room. Inside the box was placed a fan for the purpose of circulating the air and thus keeping the box at a uniform temperature throughout. The desired temperature was obtained by means of an electric heating coil placed in the center of the box. During the tests, readings were taken every ten minutes of the temperature inside and outside the box and of the voltage and amperage input. When the readings became constant they were considered acceptable and the rate of transmission in B.t.u. per hour per square foot was calculated from the formula

$$k = \frac{3.412 \times A \times V}{\text{mean area of box surface} \times \Delta T} \ldots\ldots [3]$$

where A = ammeter reading in amperes.

V = voltmeter reading in volts

3.412 = heat equivalent of watts per hour

ΔT = temperature difference.

The calibration curve for the various temperature differences is plotted in Fig. 2.

After calibration the removable corkboard side was taken off and replaced by a glass plate ⅛ in. thick. Thermometers were placed at distances of ¼ in., ½ in., 1 in., 3 in., and 28 in. from the inside surface, also on the inside and outside surfaces and 28 in. from the outside surface. Tests were made in the same manner as when the box was calibrated.

All tests were run until the respective thermometers had maintained constant readings for some time. The arrangement of thermometers afforded ample opportunity to determine the temperature gradients.

Owing to the few available thermometers, it was not possible to run tests for inside and outside gradients simultaneously. Consequently the thermometers were rearranged as follows for the outside gradient tests: 28 in. inside, inside surface, outside surface, and ¼ in., ½ in., 1 in., 3 in., and 28 in. outside. All tests so far had been run with circulating air inside and still air outside. During this set-up, however, air currents were induced by a motor-driven fan which forced

air through a narrow slit-like aperture 1 in. wide and discharged across the surface of the glass with mean velocities at the thermometers of 800 and 1100 ft. per min. for two tests, respectively. Results of the outside gradient tests are plotted in Fig. 3, herewith shown. Two curves obtained under conditions of temperature and temperature range similar to those of the inside gradient tests were plotted in Fig. 4, together with the inside gradients as though they were obtained simultaneously.

On account of breakage, the plain glass window was now replaced by a four-pane window sash. Thermometers were placed at 28 in. inside, the inside surface, the outside surface and 28 in. outside the window. Tests were now run in the same manner as the preceding ones, especial care being taken to keep constant voltage and amperage in the heating coil, since these tests were primarily transmission tests. The combined transmission coefficient (k_1) of the window glass was calculated from the following formula:

$$k_1 = \frac{3.412\ V\ A - k_2\ S_1\ (\Delta T) - 0.8\ S_3\ (\Delta T)}{S_2 \times (\Delta T)} \ldots . [4]$$

where V = volts in heating coil

A = amperes in heating coil

S_1 = mean area of surface of 5 sides of corkboard box, sq. ft.

S_2 = mean area of surface of window panes, sq. ft.

S_3 = mean area of surface of sash (wood), sq. ft.

(ΔT) = temperature difference (inside—outside), deg. fahr.

0.8 = coefficient of transmission of wood

k_2 = coefficient of transmission of corkboard

The coefficient k_1 was calculated for various temperature differences as shown above and the results plotted in Fig. 5.

The conductions of the two air surfaces and the glass were determined similarly to the combined transmission coefficient, save that the value of (ΔT) in the denominator varied as the temperature differences of the various layers of material concerned. These curves are likewise plotted in Fig. 5 for the purpose of comparison.

SAMPLE CALCULATIONS

When (ΔT) = 23.15 deg. fahr.,

k_1 (combined transmission coefficient of glass) =

$$\frac{(3.412 \times 49.5 \times 4.51) - (0.8 \times 0.58 \times 23.15) - (117.3 \times 23.15)}{21.4 \times 23.15} =$$

$$\frac{770 - 10.75 - 277}{495} = \frac{482.25}{495} = 0.974$$

$$C_2 = \text{conduction of glass} = \frac{482.25}{21.4 \times 1.26} = 17.88$$

$$C_1 = \text{Conduction of inside air surface} = \frac{482.25}{21.4 \times 7.93} = 2.84$$

C_{o_1} = conduction of outside air surface =

$$\frac{482.25}{21.4 \times 13.96} = 1.615$$

DISCUSSION OF RESULTS

When plotted, all of the temperature gradients from the surface proved to be smooth curves. This result amply justified the method of testing which was employed during the entire series of tests, both gradient and transmission. In this method of testing the authors continued the test until constant readings in the respective thermometers had been maintained for some time. The time elapsing before this condition was obtained varied between two and eight hours.

The inside gradients bent down sharply within the first quarter of an inch. Then the curves grew flatter, until at a distance of ½ in. from the surface of the glass the curves became constant. The outside gradients were more gradual in character, the major part of the drop occurring in the first two inches from the glass for still-air conditions, while the gradients obtained under moving air were considerably flattened and reached a nearly constant value within the first inch.

These results would indicate that the circulating air inside

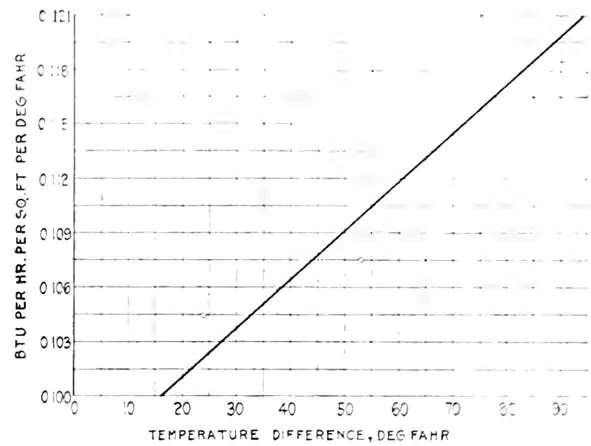

FIG. 2 TRANSMISSION OF CORKBOARD BOX

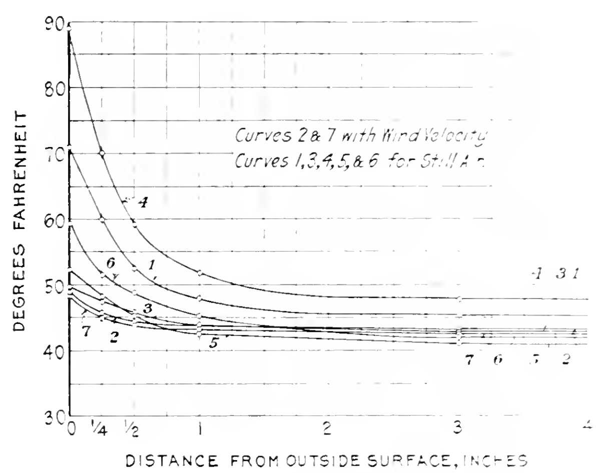

FIG. 3 OUTSIDE TEMPERATURE GRADIENTS

cut down the air resistance film at the surface of the glass and thus increased the conduction of the air layer.

Under still-air conditions the outside surface resistance was considerably greater than with moving air. This was undoubtedly due to the fact that much heat was carried away by convection.

These tests indicate that the resistance is greatest very close to the surface of the glass and that when performing experiments in heat transmission it is best to place the outside thermometer not less than 2 in. from the surface under still-air conditions; and not less than 1 in. under moving-air conditions when the air velocity is greater than 800 feet per minute.

The combined transmission coefficients and the conduction

values for the glass inside air surface and outside air surface were calculated by formula (1) and are as follows:

	Temperature Range, Deg. Fahr.			
	[illegible]	10–37	51–45	73–59
Combined transmission	0.971	1.070	1.130	1.165
Conduction of glass	17.880	18.050	19.800	19.890
Conduction of inside air surface	2.840	3.315	3.650	3.560
Conduction of outside air surface	1.615	1.750	1.850	1.900

The combined coefficient values check up fairly well with the values 0.96 (dry glass) and 1.1 (wet glass) for a single window 1/8 in. thick, given in Greene's Elements of Heating and Ventilation. Moreover, they show that the transmission varies linearly with the temperature differences, as the curve plotted in Fig. 5 will demonstrate.

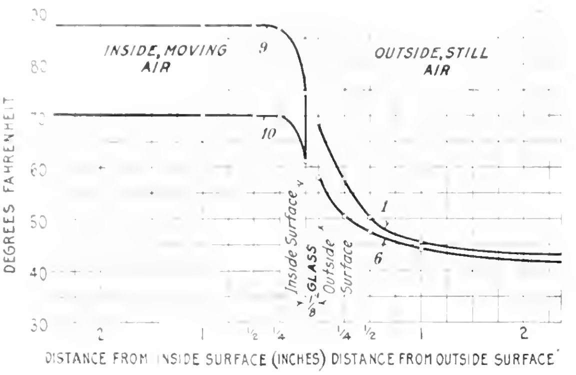

Fig. 4 Combined Inside and Outside Gradient

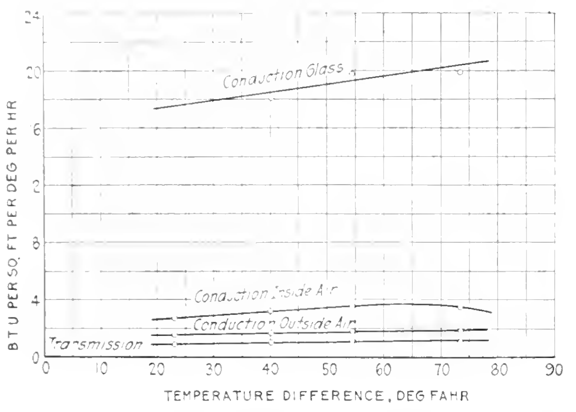

Fig. 5 Conductions Through Air Surfaces and Glass

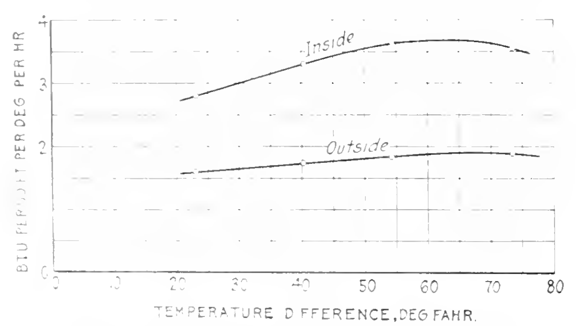

Fig. 6 Conduction Through Air Surfaces

The conduction values for the glass under the same temperature differences show that they also varied in the same way as the combined transmission values.

The conduction values for the air surfaces confirm the results of the gradients, in that the resistance of the outside air surface is shown to be considerably less than that of the inside air surface. Curves of the surface resistance plotted to an enlarged scale in Fig. 6 show that the conduction of the surfaces is greatest at points where the temperature ranges vary from 65 deg. to 75 deg. This seems to indicate that there is a saturation point at which the transmission through the air layer cannot be increased. The writers believe that it would be highly desirable that further investigations be undertaken in order to check up this point.

Fig. 5 shows the relationship between the conductions of the air surfaces and the glass. It can be seen that the resistance of the glass is very slight as compared with that of the air surfaces. This proves that in figuring transmission through glass the resistance of the air layers at the given conditions will be the primary factors, since from the figure it is shown that they form the bulk of the resistance which goes to make up the combined transmission factor. In connection with this point it is interesting to note the investigations carried on by Professor Moyer in the Pennsylvania State College Thermal Testing Plant, and described in the *A. S. H. E. Journal*, Vol. 2, No. 3. Professor Moyer's results indicated that the influence of air velocity on transmission through glass caused the transmission coefficient to vary from a value of 1.263 at zero velocity to 4.207 at a velocity of 1200 ft. per min. This illustration further proves the extreme importance of the air surface resistance on the combined transmission factor.

Consequently, the subject of air resistance seems worthy of careful investigation as to its behavior under varied conditions. The writers in suggesting further investigation along this line would say that they consider thermocouples preferable to resistance thermometers. Resistance thermometers, on account of their appreciable size and consequent susceptibility to radiation, make very accurate surface readings impossible, while the fine-point contact of the thermocouple makes it very desirable in this connection. Delay in obtaining thermocouples caused the writers to use resistance thermometers in these tests.

The writers are indebted to Prof. R. B. Fehr of the Pennsylvania State College Thermal Testing Plant for some of the data used.

CONCLUSIONS

A summary of the more important results obtained in the tests is as follows:

1 The gradient tests demonstrate that the greater part of the air-layer resistance occurs at the outside and within the first half inch of the surface.

2 Whenever glass or any other good conductor is used as the transmission medium, the resistances of the inside and outside air surfaces play the major part in determining the combined transmission coefficient.

3 The tests show that the transmission through glass and through corkboard with temperature differences ranging from 20 deg. to 80 deg. varies linearly with these temperature differences.

The writers wish to acknowledge much valuable assistance received from Prof. A. J. Wood and R. B. Fehr, and from the Penn State College.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Steam Locomotive Practice

To the Editor:

Among the papers constituting the Symposium on Steam Locomotives held by the Minnesota Section, I find a number of points of interest, which might be considered more extensively with profit. Prof. G. L. Hoyt calls attention to the fact that, in many cases, the use of special heat-treated steel has not been accompanied by a modification in design, so that the advantages of the higher-priced metal could be fully obtained. This is a point that is not readily understood, and is especially true in the case of springs, where the alloy steel costs double and should have double strength, but the manufacturers recommended the same load limits, viz., 70,000 to 80,000 lb. per sq. in., that had been used for years in plain carbon steels. It was explained that you had double the "factor of safety" that you obtained with carbon steel, but this never appealed to the writer as being a sound engineering argument. Factors of safety are too often "factors of ignorance," and as such are not desirable quantities to increase, especially at double the price.

These recommendations to use high-priced heat-treated alloy steels without realizing the benefits for which we pay by a reduction in the quantity of metal used, always convey the impression that the particular heat treatment used may *not* give us all that is claimed for it. Heat treatment is quite a difficult process to control properly in a large plant, where the conditions of operation are evidently very different from those that obtain in an experimental laboratory, where the whole treatment is under the eye of a specialist instead of depending upon ordinary labor. Pyrographic charts will tell what temperatures *have existed* at certain *points* in the *furnace,* but the temperature of the particular piece under treatment is quite another matter.

The writer does not wish to be considered skeptical of the value of alloy steels—far from it, but he has seen so many instances of things being "seldom what they seem" in the heat-treated line that he does not always have as much faith in the results of that process as he would like to have, and it seems possible that such fears may be the basis for maintaining old dimensions in the parts made of alloy steels.

Coming to Pulverized Fuel in Locomotives, the writer is in hearty accord with the efforts of Mr. Muhlfeld to obtain greater output from locomotives by this method of combustion. Many years before locomotive stokers achieved the success which they now enjoy, he (the writer) pointed out the necessity for increasing the steam output beyond the human muscular limits of the fireman, which were about 5000 to 6000 lb. of coal per hr., and favored the introduction of stokers on locomotives which should have the firebox especially designed for this purpose, instead of trying to crowd in the stoker apparatus and mechanism where the construction was not suitable for producing the best results. The same must be true of pulverized coal, and prejudice in adhering to conventional lines should not be allowed to interfere with the success of this method of firing locomotives. This has been the crucial point in many improvements, and fear to leave what our fathers have done has sounded the death knell of many valuable efforts for progress.

At the present time the success of feedwater heaters on locomotives seems to be more dependent upon the pump than any other feature of the device. Simple as this part of the problem seems to be, it is one very difficult of satisfactory solution. Reciprocating pumps jar themselves and their parts loose and go out of commission just when the engineer has neither time nor opportunity to "tinker" with them. Rotary pumps at high speed have difficulties of their own, due largely to the unsatisfactory foundations which must be furnished by the locomotive structure. Bent spindles and other troubles follow insufficient rigidity, and the small space available for this apparatus prevents securing the best results. The weakest link in a chain is often located where we least expect, and compromises the whole structure by its breakdown. So an unsatisfactory pump will put a "curse" upon a feedwater system that it cannot survive, no matter how efficient the heater.

Geo. R. Henderson.

Philadelphia, Pa.

To the Editor:

The symposium on steam locomotives, held by the Minnesota Section on March 10, was certainly most instructive, but I feel that one point in connection with the various appliances and devices described was not given sufficient importance. To one familiar with development of steam locomotives in the past few years, there is no question but that the superheater and brick arch have had a very intimate connection with the increase in size and power of our locomotives. The railways have been continually seeking for larger and larger units of power, with but slight changes in physical limitations under which this power must operate (weight per pair of wheels, height and width limits and amount of coal which can be fired per hour), and the increased capacity afforded by superheat and the brick arch has permitted an increase in the size of locomotives far beyond that which would have been possible without them.

In the papers which were read descriptive of various improvements, emphasis was laid upon the economies in operation which these improvements effected. It has been the history of railroading that advantage is at once taken of any device which makes for economy or efficiency in obtaining *additional capacity.*

How much has already been accomplished in this matter is evident from a comparison of the horsepower output of a typical first-class locomotive built about 1904-05 and that of one of recent design. An average fireman can handle about 5000 lb. of coal per hour. In 1904 we were obtaining from our best designs of simple locomotives without superheaters about 1100 to 1200 i.hp. per hour from 5000 lb. of coal. To-day we are obtaining from the same amount of coal about 2000 to 2100 i.hp. per hour.

These latter figures were obtained from locomotives having superheaters and brick arches, together with other refinements of design introduced in the past few years. It is evident that the enormous strides in increased capacity and size could not have been made had it not been possible to obtain more work from a pound of coal by taking advantage of the increased efficiency due to these improvements.

Two of the latest developments which will make possible still further increases in capacity and power, and which were not included in the above comparison of locomotives in 1901 and 1905 and at the present time, are the feedwater heater and the use of pulverized fuel. Both of these developments are unquestionably capable of yielding material economies which will undoubtedly be utilized in still further increases in the capacity of locomotives.

In the past there have often been statements made that we had reached the limit of size and power of locomotives, but it is significant that of late there have been fewer of such statements. The improvements and developments which were described at the meeting of the Minnesota Section have removed many of the limitations which previously confronted locomotive designers, until at the present time men who are familiar with the latest developments in this field hesitate to make any predictions as to limits of capacity and size of future steam locomotives.

W. E. WOODARD.

Lima, Ohio.

Mobile Armament for Defense

TO THE EDITOR:

Replying to the comments of Mr. Arthur F. Cary on Mobile Armament for Defense, published in the September issue of THE JOURNAL, I beg to state:

1 The standardization of ammunition for various calibers of guns is a very interesting matter, but is foreign to the subject under discussion.

2 As to the practicability of the gun having a breech block sliding against a surface plate: There is no tendency to dent the surfaces, which are hardened and are of sufficient area to withstand the load imposed. This load is a static pressure and is not in the nature of a blow; means being provided to bring the surfaces in contact, although a working clearance is allowed when elevating the gun.

3 With reference to the methods of supporting railroad cars from which guns of moderate size are fired: The outriggers and jackscrews have been adopted for the reason that they admit of adjustment to almost all conditions of the roadbed. In order to secure mobility it is necessary to keep the supports as nearly as possible within the limits of the roadbed. Beyond the actual roadbed the ground may be unsuitable to support any load. The tripod arrangement suggested by Mr. Cary presents several difficulties. The struts would have to extend from a point only a little below the trunnions, otherwise they would be subjected to a bending movement and would have to be made heavy. It would be interesting to see this tripod arrangement worked out for firing a gun from a car on a banked track say eight feet above a New Jersey marsh.

4 The independent drive for railroad cars is in use to some extent on the Pacific Coast. This is one of the good things that come from the West and travel East. It may replace the horse cars in some parts of New York.

ANDREW M. COYLE.

New York, N. Y.

Strength of Boiler Furnaces

TO THE EDITOR:

Referring to Par. 6 of the letter from Mr. John Airey in the July number of THE JOURNAL, I will quote the part of the Board of Trade rules pertaining to pressure allowance on plain circular furnaces, as follows:

$$\text{Plain Furnaces}^1. \quad \text{W. P.} = \frac{C \times T^2}{D(L+1)}$$

TABLE OF VALUES FOR C

Longitudinal Seams of Furnace	Iron		Steel
	Drilled	Punched	Drilled
Single butt straps double-riveted, or double butt straps single-riveted	90 000	85,000	99,000
Single butt straps single-riveted, or lap beveled and double-riveted......	80,000	75,000	88,000
Lap not beveled, double-riveted .	75,000	70,000	82,500
Lap beveled, single-riveted..... ..	70,000	65,000	77.000
Lap not beveled, single-riveted......	65,000	60,000	71,500
Longitudinal seams welded	90.000		99,000

In no case should the working pressure exceed the values found by the following formulæ:

$$\text{W. P.} = \frac{9000\ T}{D} \text{ for iron}$$

$$\text{W. P.} = \frac{9900\ T}{D} \text{ for steel.}$$

From this it will be noted that for a plain circular furnace

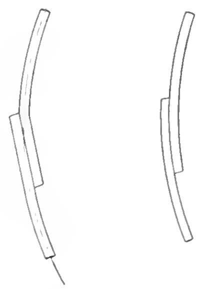

FIG. 1 FIG. 2

FIG. 1 BEVELED LAP SEAM

FIG. 2 ORDINARY LAP SEAM

with a single-riveted lap seam the formula is: $\frac{77{,}000\ T^2}{(L+1)D}$. This gives a pressure of 75 lb. on the furnace of the dimensions given by Mr. Airey, as stated in my communication in the February issue of THE JOURNAL. The constant 77,000 pertains to furnaces in which the single-riveted lap seam is properly formed or "beveled" so that the furnace cross-section is a true circle (Fig. 1).

When such a joint is made as shown in Fig. 2 the constant to be used is 71,500, which would give a pressure of 69 lb. without further deduction for the efficiency of the longitudinal joint.

Comparing the above constants and assuming 100 per cent for the collapsing strength of a flue with a welded seam or one with a double butt-strap joint, which are the easiest to make truly round, we get an efficiency of 71,500/99,000 = 72.2

[1] Copied from quotation of Board of Trade rules in Stromeyer's Marine Boiler Management and Construction.

per cent allowed by the Board of Trade rules for the kind of joint shown in Fig. 2.

While Mr. Airey's mathematical analysis of the efficiency of this joint in compression, which was published in the Journal of the American Society of Naval Engineers, appears a safe approximation, it would not seem that the theoretical result of 27.6 per cent (or about two-fifths of the Board of Trade allowance) he thus obtains need seriously be considered in view of the experience of several decades during which the Board of Trade constants have been operative unchanged in localities where boilers with (riveted) furnace flues always have been proportionally far more numerous than in the United States. It appears quite probable that the failure of the actual flue mentioned by Mr. Airey was due to general out-of-roundness in addition to the fact that the most unfavorable joint was used.

Upon the strength of Mr. Airey's analysis he is not justified in referring in a general way to "the weakness of a lap joint," since a lap joint that is properly formed as in Fig. 1 does not produce the unfavorable feature of making a cylinder out of round, and his analysis pertains only to Fig. 2.

One important point this discussion has brought out is that from the present wording the A.S.M.E. Boiler Code rules may be construed as permitting the use of longitudinal lap joints that are not properly formed for furnace flues, as all lap joints in compression should be, so that true circularity is obtained. It might be well to specifically prescribe this in the various paragraphs of the Code where longitudinal lap joints for flues are mentioned, just as the proper curvature for longitudinal joints of boiler shells now is prescribed.

H. J. Vanderéb.

Hartford, Conn.

WORK OF THE BOILER CODE COMMITTEE

Ten Years of Boiler Standardization

The conception of a standard specification for steam boilers was first advocated, I believe, by Mr. Joseph H. McNeill, who for many years was the very able chief inspector of the State of Massachusetts Boiler Inspection Department, and through the very earnest endeavors of Mr. McNeill and the operating engineers of Massachusetts, most ably sponsored by the late Hon. Curtis Guild, Jr., Governor of Massachusetts and later Ambassador to Russia, the Massachusetts Board of Boiler Rules was created. The writer looks back with pleasure to being one of the members of the original Board, on which he represented boiler-using interests, and which included Joseph H. McNeill, Chairman; Frederic H. Keyes, representing boiler-manufacturing interests; Robert J. Dunkle, representing boiler-insurance interests, and William M. Beck, representing operating engineers.

Upon the retirement of Mr. Frederic H. Keyes, Mr. Bartholomew Scannell, of Lowell, Mass., one of the patriarchs of the boiler industry in this country, was appointed in his place. Upon Mr. Scannell's resignation, Mr. Henry H. Lynch was appointed.

The late Mr. Thomas R. Armstrong was also a member of the Massachusetts Board of Boiler Rules at one time.

The first meeting of the Board was held on July 5, 1907, in a very small and hot room on the fifth floor of the State House at Boston. At this meeting Mr. McNeill stated to the other members of the Board his ideas of a standard specification for all stationary boilers to be used within the Commonwealth of Massachusetts.

We forthwith set to work to formulate a standard which would be first of all safe, and second commercial. We held meetings weekly and oftener for practically the first three years of the service. Incidentally it might be mentioned that the correspondence was very prolific; it came from all known authorities whom we could interest enough to send us any good data they had on boilers which would make the steam boiler of the future reasonably safe, and almost without exception we had prompt and efficient replies from all those well qualified to give advice.

From time to time, as we were in a position to do so, we issued pamphlets of instructions to boiler manufacturers and inspectors, stating how the rules should be applied in the construction of boilers, until we published the Rules of August 5, 1909, which was the last and main issue made by the original members of the Massachusetts Board of Boiler Rules and embodied all that was necessary for the guidance of those manufacturing and inspecting stationary steam boilers for the Commonwealth of Massachusetts for that period.

While this work was going on, the forces in the Inspection Department were augmented, more rigid watch was kept of existing boilers, and more thought, patience and skill put into the manufacture of new boilers; in other words, the educational process was advanced and has advanced ever since Mr. McNeill started this system.

In the meantime, the writer made a trip to Europe and interviewed several of Europe's greatest boiler engineers with special reference to additions or deductions from our Rules, and we were very highly complimented in Europe on the rules formulated.

The present Massachusetts Board of Boiler Rules consists of

Geo. A. Luck, Chairman.

Frederick A. Wallace, Representing Boiler-using Interests.

Henry H. Lynch, Representing Boiler-manufacturing Interests.

Robert J. Dunkle, Representing Boiler-insurance Interests (member of Board since its inception).

Edward D. Mullane, Representing Operating Engineers.

In addition to its boiler-standardization work the Board has formulated very valuable air-tank regulations.

In 1911 the late Col. E. D. Meier, then president of The American Society of Mechanical Engineers, suggested in his wonderful foresight that The American Society of Mechanical Engineers undertake the work of standardization of steam boilers in a more complete manner than was possible with the State of Massachusetts, and the writer was appointed Chairman of the original committee of The American Society of Mechanical Engineers for the purpose of creating a standard for that Society. This committee was called The Committee to Formulate Standard Specifications for the Construction of Steam Boilers and Other Pressure Vessels and for their Care in Service, and originally consisted of

John A. Stevens, Chairman	Chas. L. Huston
Wm. H. Boehm	Edward F. Miller
Rolla C. Carpenter	H. C. Meinholtz (Deceased)
Richard Hammond	E. D. Meier (Deceased)

Upon the death of Mr. Meinholtz, Col. E. D. Meier was appointed in his place.

Colonel Meier took a most active part in the formation of the A.S.M.E. Boiler Code, and up to within a few days of his death had it constantly before him. It is one of the regrets of the members of the Boiler Code Committee that he could not have lived to have seen the fruition of the work he so wisely started.

The A.S.M.E. Committee proceeded on similar lines to those followed by the Massachusetts Board of Boiler Rules in counseling with all qualified authorities, manufacturers and large users of boilers, producing its preliminary report and thereafter issuing at different times other preliminary reports up to the issue given to the public in 1914.

At one stage in the work it was found advisable and necessary to amplify the original Committee by appointing an Advisory Committee composed of some of our most celebrated steam engineers, for it was believed that the great interests of our country should not have "taxation without representation," and it has always been admitted that boilers built to the standard of The American Society of Mechanical Engineers cost more money than boilers built otherwise, and are indeed worth more.

In appointing the Advisory Committee, men were chosen to represent all of the large interests affected, such as railroads, consulting engineers, large manufacturers of different types of boilers and engineering schools. Their keen interest was thus secured in the promulgation of standards among our engineering institutions, steam-heating boiler manufacturers, water-tube-boiler manufacturers, boiler-insurance companies, threshing interests and boiler users.

The members of this Advisory Committee consisted of the following:

F. H. Clark, Railroads.
F. W. Dean, Consulting engineers.
Thos. E. Durban, Boiler Manufacturers' Association, Uniform Specifications Committee, for all types of boilers.
Carl Ferrari, National Tubular Boiler Manufacturers' Association.
Elbert C. Fisher, Scotch marine and other types of boilers.
Arthur M. Greene, Jr., Engineering education.
Chas. E. Gorton, Steel heating boilers.
A. L. Humphrey, Railroads.
D. S. Jacobus, Water-tube boilers.
S. F. Jeter, Boiler insurance.
Wm. F. Kiesel, Jr., Railroads.
W. F. McGregor, National Association of Thresher Manufacturers.
M. F. Moore, Steel heating boilers.
I. E. Moultrop, Boiler users.
Richard D. Reed, National Boiler & Radiator Manufacturers' Association.
H. G. Stott.[1] Boiler users.
H. H. Vaughan, Railroads.
C. W. Obert, Secretary to Committee.

In the appointment of the Advisory Committee, we were most fortunate in selecting men who proved to be real workers, and who moreover were naturally possessed of analytical minds, men not afraid to admit when they were wrong and not afraid to be insistent when they were right.

The writer wishes to mention especially the great assistance given the Committee throughout the early stages of the formulation of the A.S.M.E. Boiler Code by Mr. Henry Hess, Vice-President of the Society, who counseled with and guided us with special reference to our conferring with other large societies interested in standardization work, notably the American Society for Testing Materials, and also other societies which were more or less interested in a boiler standard. He also very wisely advised us not to have anything to do with legislation or politics; had we not heeded this advice we would probably have caused the downfall of the Code early in its life.

Space prevents mentioning the great assistance accorded the Committee by manufacturers of boiler material, irrespective of their own desire to manufacture only one standard material for boilers, also the great help given by the boiler-insuring interests, and that offered by the railroad interests of America, and by the large boiler users.

Throughout the entire formulating period of this work the writer was most ably assisted by his associate-engineer, Mr. Walter Slader, and he wishes here to give this gentleman credit for the very valuable work he did throughout this long and arduous task. In passing, he wishes also to give all due credit to *Power*, *The Boiler Maker*, and several other engineering periodicals which have from time to time issued articles in sympathy with the movement.

The work of the Boiler Code Committee of The American Society of Mechanical Engineers was founded on the standards originated by the Massachusetts Board of Boiler Rules, but it should be noted that the work is a great deal more complete and far-reaching than the Massachusetts Standard. In the first place, the A.S.M.E. Code specifies in detail the chemical and physical properties of all material entering into the construction of boilers, and gives rules, formulæ and tables which have been checked and rechecked by men of national reputation and in many cases verified by testing laboratories; that is to say, in many cases, rules or formulæ were withheld until actual tests in laboratories had been made in order to prove the mathematics.

Therefore, it is with pleasure that we note that the Code has been adopted, or is in the process of adoption, in great states such as New York, New Jersey, Pennsylvania, Ohio, Indiana, Michigan, Wisconsin, Minnesota and California, and such cities as Kansas City, Scranton, Pa., and St. Louis, Mo., and even in the Argentine Republic and the Republic of Paraguay, South America.

This would indicate that the Code has been through a very severe process of trial and has been found to be, as stated, the best in existence for governing the construction and inspection of stationary boilers.

It is also gratifying to the writer to note that, according to Specification No. 2362 for power-plant equipment at the Naval Training Station, Newport, R. I., boilers and accessories used by this department are to be in accordance with the A.S.M.E. Boiler Code.

As the writer has many times stated in public, the Boiler Code of The American Society of Mechanical Engineers is intended for the young engineer. Many of our older engineers know all that is in the Code and more, but in looking forward to the future, the writer, for one, is always especially careful in the endeavor to see to it that our young engineers are started correctly.

It is interesting to the writer to review the enormous amount of money spent directly and indirectly by the engineers having to do with the standardization of boilers in America. It was stated authoritatively in New York at the completion of the A.S.M.E. Boiler Code, Issue of 1914 with Index, that the work, if paid for at ordinary professional rates, would have cost at least a quarter of a million dollars.

[1] Deceased.

Further, it was stated by a member of the Boiler Code Committee in New York recently that by the time the Code is universal in the United States, the cost will approximate a million dollars.

To promulgate the Boiler Code throughout the Union, a group of public-spirited citizens organized what is known as the American Uniform Boiler-Law Society, the officers of which are:

Thomas E. Durban, Chairman Administrative Council.
E. R. Fish, American Boiler Manufacturers' Association.
H. P. Goodling, National Association of Thresher Manufacturers.
F. W. Herendeen, National Boiler and Radiator Manufacturers' Association.
M. F. Moore, Low-Pressure Steel Boiler Manufacturers.
I. Harter, Jr., Water-Tube Boiler Manufacturers.
John H. Wynne, Locomotive Manufacturers.
Walter Plehn, Steam-Shovel Manufacturers.
H. N. Covell, Hoisting-Engine Manufacturers.
Chas. S. Blake, Boiler Insurance Companies.
John Hunter, National Electric Light Association.
D. J. Champion, Boiler Materials.

The Chairman states that this organization has expended on an average $1000 per month since starting on the work of interesting the States to adopt the A.S.M.E. Code. This money is being spent to bring the Code prominently before the people and to explain the advantages accruing from its use.

On December 4 and 5, 1916, the American Boiler Code Congress was held at Washington, D. C., at which the official representatives of twenty-three states were present, and it was unanimously voted to approve the Boiler Code of The American Society of Mechanical Engineers.

We also had a very able sponsor from Toronto, Canada, in Mr. D. M. Medcalf, Chief Boiler Inspector of Ontario, who is fully alive and awake to the advantage of having the same Code in force in the Canadian provinces as in the United States.

The writer would mention that whatever assistance he has given to this work has been given in the spirit of true Americanism: to wit, "for the good of the service"—and incidentally this service has been of great educational value to him. He has made acquaintances everywhere and a great many friends in the pursuit of this work and has had the pleasure of acting as Chairman of The American Society of Mechanical Engineers' Boiler Code Committee since its inception.

For those who do not know, the idea of standardization is strictly American, being an American creation: for instance, the standard fire-hose coupling, the standard berry basket, the standard electric-lamp socket, the standard cement specification, standard structural shapes, standard screw threads, and of late, the standard ship and the standard aeroplane engine; and a standard boiler construction using one standard of boiler materials and accessories would naturally appeal to the highest and broadest type of business men in the spirit of maximum conservation and efficiency.

For the states which have not adopted a standard, the only work that is necessary is of an educational nature: for, when the entire case is fully explained, the Code is usually adopted. To those states which have not adopted the A.S.M.E. Code, the writer would recommend its adoption as being the most complete boiler law of any in existence at the present time.

Further, a permanent committee has been established by The American Society of Mechanical Engineers for adding to and deducting from the A.S.M.E. Code as the art advances, and also to assist in the interpretations of the Code in states and municipalities where the engineers are not conversant with its rulings. In other words, The American Society of Mechanical Engineers very advisedly puts itself in the position of a "clearing house" for boiler engineering.

The writer's thought has always been to have the Code so complete that all that was necessary in ordering boilers was to name the type, amount of heating surface required and the working pressure desired, and where credits and reputations were good, a postal-card order might suffice, since the fact that a boiler had been properly stamped with the symbol of The American Society of Mechanical Engineers would be positive proof that all the purposes of the contract and every detail of the Code requirements were fulfilled.

The A.S.M.E. Code is the result of the combined ideas of several thousand engineers who have assisted the Committee from the start up to the present time in producing the right recommendations.

The Code is now under its first revision and the revised printing will be ready for the public within a few months. The proposed revisions are being published from time to time in The Journal with the idea that all those interested be given an opportunity to discuss them before they are brought to their final form for adoption. The greater part of the revisions will be made to clarify the text but not to change the intent of the original Code.

The writer has often been asked how many boilers there are in America, to which he would answer that as near as he can glean there were about 600,000 power boilers in 1914. He would also state that the boiler business in America is said to amount to $500,000,000 per year.

In closing, let it be said that it is the earnest wish of the writer that all those not conversant with the Code may become so, and may assist in putting it into general service at the earliest opportune time. He also wishes to thank all those who have assisted in any way in the promulgation of the A.S.M.E. Standard.

John A. Stevens.

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee.. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in The Journal, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 158, and 167-172, inclusive, as formulated at the meeting of July 27 and approved by the Council on August 15, 1917. In this report, as previously, the names of inquirers have been omitted.

Case No. 166

Inquiry: Is it permissible under Par. 331 of the A.S.M.E. Boiler Code to omit the stamping from tube heads of boiler drums where they are so flanged and corrugated, as shown in Fig. 1 that the original stamping cannot be preserved, or would it be allowable to stamp the heads with lot numbers as they come off the press so that they may be identified afterward?

Reply: It is the opinion of the Committee that the construction shown is classed with headers and does not require the stamp to be visible after the part is formed.

Case No. 167

Inquiry: Can some allowances be made by the Boiler Code Committee in the specifications for steel castings in the Boiler Code, with regard to the chemical composition of the ladle analysis, to compensate for the difficulty at the present time in obtaining castings low in sulphur and phosphorus?

Reply: The matter of modifications in the specification for steel castings has already been referred to the American Society for Testing Materials, and the question is up for consideration at this time, but no decision has been reached.

Case No. 168

Inquiry: Referring to Case No. 113d, are we to understand that all plates forming any part of a boiler, no matter

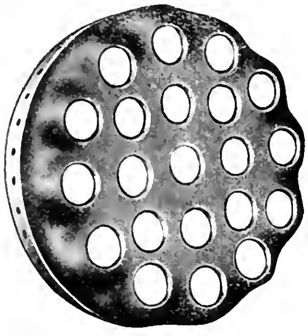

Fig. 1 Flanged and Corrugated Tube Head

whether they are used flat, bent, or flanged, either hot or cold, must be finished on all edges by either planing, milling, or chipping?

Reply: The word "calking" was inadvertently omitted from the reply in Case No. 113*d*, and the inquiry is answered by the reply in that Case which should read as follows:

> *Inquiry: d* Is Par. 257 intended to do away with the bevel shear for finishing the calking edges of plates, and does it mean that the plate edges may only be planed, milled or chipped?
>
> *Reply: d* According to Par. 257 of the Code, in order to eliminate the incipient cracks left by shearing, the *calking* edges of the plates must be finished by planing, milling or chipping, whether they are sheared straight or beveled.

Case No. 169

Inquiry: Can a check valve where a valve stem is provided to permanently close the valve when the stem is screwed down, and thus form a combination stop and check valve, be regarded as both a stop valve and a check valve as required by Par. 317 of the Boiler Code? A device of this character is commonly applied to feed connections on one type of water tube boiler. Is it necessary where this fitting is used on the feed connection of a boiler set in battery to provide such connection with an additional check valve and a globe valve between such check and the source of supply?

Reply: It is the opinion of the Boiler Code Committee that this combination check and stop valve should be classed only as a stop valve.

Case No. 170

Inquiry: Can staybolt iron made from hammered blooms consisting of wrought iron horseshoes, be considered as meeting the requirements of the specification in the Boiler Code for staybolt iron, if the horseshoes are originally made from puddled iron?

Reply: It is the opinion of the Committee that Pars. 139 and 140 in the specifications for staybolt iron require that the material forming the box pile shall consist of bars the full length of the pile. If the horseshoes which are used are first worked into the bars described in Par. 140*b*, then cut to the necessary full length and made into the box pile as described, the material will meet the specifications. It is essential that purchased scrap be eliminated.

Case No. 171

Inquiry: Is it essential that the 10 per cent limit of variation allowed in Par. 285 of the Boiler Code for the springs of A.S.M.E. Standard Safety Valves, be met where it entails serious hardship to obtain springs so close? Certain manufacturers supply only three springs for the entire range from 25 to 250 lb.

Reply: It is the opinion of the Committee that this is a matter to be taken up with the particular valve manufacturer in question, as the variation called for in the Code can be and is being met.

Case No. 172

Inquiry: a Is it to be understood from Par. 296 that ordinary commercial iron or steel pipe may be used from the steam space of a boiler to the upper connection of the water column and that the connection from this pipe to the steam gage may be made of copper pipe?

b Is it permissible under Pars. 320, 321, and 322 of the Boiler Code which require the water connections to water columns to be made of brass and provided with a cross to facilitate cleaning, to connect a drain pipe into one unused opening of the cross and insert a cast iron plug in the other?

c Relative to the arrangement of connections indicated in Inquiry *b*, is it allowable under Pars. 320, 321, and 322 of the Boiler Code to use a malleable iron bushing and a commercial iron or steel pipe to which the drain valve may be connected?

Reply: a This understanding of the requirement of Par. 296 is correct.

b The Boiler Code requires a brass connection from the boiler to the water column including the cross. Any other part can be as described in the inquiry.

c The arrangement described would be considered as in accordance with the Code.

According to *Motorship*, there has been considerable discussion in the last year in regard to the feasibility of concrete ships, and now an experiment is to be made and an ocean-going vessel of large size, in this material, is to be thoroughly tried out. Plans for the ship have been prepared by Leroy Caverly, a marine engineer of San Francisco, and if tests now under way are successful, work on the vessel will shortly be commenced. As planned, this experimental concrete ship is to be 300 ft. over all, 46-ft. beam, with a depth of 24 ft., and be 5000 gross tonnage and powered by steam turbines of 2500 hp. It is claimed that such a craft will have a dead weight no greater than a wooden vessel of the same size, and can be completed in ninety working days at a cost of only $64 a ton. It is not probable that power will be installed at once, but the hull will be towed on a test sea trip.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

THE Secretary is frequently asked what the Society is doing in connection with the war, and he is happy to say that the Society is not only individually rendering a special service, but it is also coöperating with the other societies in most constructive work. It might be well to here review the several activities of the Society which have bearing on the war situation, but before doing so it should be mentioned that the special activity now occupying our attention to the greatest degree is the work of the Engineering Resources Committee, Mr. George J. Foran, Chairman—that of furnishing specialists for the numerous demands of the Government and the industries generally.

Our circular letter to the membership enclosing the Personal Classification Blank has brought in to date over six thousand replies, and upward of four thousand of these have been collated in the most complete manner. To carry out this work of collation the systems employed by the universities in similar work, by the insurance companies, the Census Bureau and the Bureau of Mines, were all carefully studied and all their good features incorporated in our own system of classification.

The Society is now furnishing names literally by the hundred in response to numerous requests for men familiar with munitions work and with researches in the widest variety of war subjects. One recent letter from Washington opens: "Our Bureau has been asked to assist in getting about one hundred of the very highest-class men having business and executive experience. These men are needed to go to France immediately to take charge of organizing ———. Please send the names and experience of any men who satisfy our requirements and who could go." Another letter from an important committee in Washington begins: "We shall consider it a favor if you could give us the names of as many as fifty mechanical engineers who meet the specifications presented in the enclosed bulletin. We should like not only the names but any ratings which you have adopted in your classification."

A further corroboration of the large number of calls being made on the Society for men is furnished by a study of the columns of the Employment Bulletin in this and the last issues of THE JOURNAL. The Positions Available section of the Bulletin last month was the largest we had ever published. This month's Bulletin is even larger than last month's.

To those members who have patriotically offered their services to the Government through the medium of the Society's Engineering Resources Committee, but who have not yet been rewarded by the assigment to duties under the Government, we can only say that their names have invariably been forwarded and that in due time, as the demand for their particular kind of service is created, the Government will undoubtedly take advantage of it.

Passing in review over the steps the Society has taken in connection with the war situation, it is interesting to state: First, the Committee on Engineer Officers' Reserve was directly responsible for the inclusion in the Hay Bill of 1916 of what is known as the Engineer Officers' Reserve Corps.

Second, the Military Engineering Committee of the Engineering Societies participated in the Preparedness Parade, in New York City, in which 10,000 engineers marched; this committee also conducted a series of lectures on Military Tactics by officers assigned by the War Department, and, further, it recruited an entire corps of 1167 men, plus about 160 others, which has already been sent to France. The expense contributed individually by twenty or more members of the Military Engineering Committee was over five thousand dollars.

This Society also took up energetically at the Spring Meeting in Cincinnati, in May last, the matter of Standardization of Gages, and an officer of the Society went to Washington and discussed the case with some of the Bureau heads, and we have reason to believe that this helped in the passing of an act providing for the work now being developed in the Bureau of Standards.

We have also a General Engineering Committee of the Council of National Defense, and the American Engineering Service Committee and War Committee of Technical Societies of the Engineering Council.

In another column the membership will be delighted to read of the prospective meetings in the West which will be attended by the president. It is a noteworthy occasion when an engineering society can obtain a visit from its president. Dr. Hollis is sacrificing both time and strength to make this tour. It is also a source of satisfaction to announce that Mrs. Hollis will accompany him.

CALVIN W. RICE,
Secretary.

Amendments to the Constitution

The following amendments to the Constitution are to be presented at the Annual Meeting, to be held in New York, December 4 to 7, 1917.

Portions in brackets show additions to the present wording of the Constitution, and portions in parentheses show deletions.

These proposed amendments were approved by the Council, presented at the Spring Meeting at Cincinnati, 1917, for discussion, and under the requirements of C57 and C58 will be presented for final vote by letter ballot.

C26 The affairs of the Society shall be managed by a board of directors chosen from among its Members, Associates and Associate-Members, which shall be styled "The Council." The Council shall consist of the President of the Society, who shall be the presiding officer, six Vice-Presidents, nine Managers, the Treasurer, and the five surviving Past-Presidents who have last held office. [The number of persons constituting a quorum of the Council shall be determined by the By-Laws.] The Secretary may take part in the deliberations of the Council, but shall not have a vote therein.

C45 The Standing Committees [of Administration] of the Society (to be appointed by the President) shall be:

(1) Committee on Finance
(2) Committee on Meetings [and Program]

(3) Committee on Publication [and Papers]
(4) Committee on Membership
(5) [Committee on Local Sections]
(6) Committee on Constitution and By-Laws
(Library Committee)[1]
(House Committee)[1]
(Research Committee)[1]
(Public Relations Committee)
(Committee on Standardization)[1]

[The appointment, organization, duties, and terms of service of Standing Committees shall be as the By-Laws provide. The Chairman of each Standing Committee shall have a seat in the Council of the Society but no vote.

There shall be other standing committees of the Society as the By-Laws provide and the Council approves.]

C47 The Annual Committees shall be:
An Executive Committee, appointed by the Council;
A Nominating Committee, appointed by the President;
Tellers, as required by the By-Laws, appointed by the President;

[1] To be designated Standing Committees, in distinction from Standing Committees of Administration, and to be provided for in the By-Laws.

[Such other committees as may be required from time to time.]

C55 The Society shall not be responsible for statements or opinions advanced in papers or in discussions at its meetings. Matters relating to [partisan] politics or purely to trade shall not be discussed at a meeting of the Society, nor be included in the Transactions.

C56 The Society shall not (approve or adopt any standard or formula, or approve any engineering or) [endorse any] commercial enterprise. It shall not allow its imprint or name to be used in any commercial work or business.

C58 The letter-ballot, accompanied by the text of the proposed amendment, shall be mailed by the Secretary to each person entitled to vote, at least thirty days previous to the closure of the voting. The ballots shall be voted, canvassed, and announced as provided in the By-Laws. The adoption of the amendment shall be decided by a majority of the votes cast. An amendment shall take effect on the announcement of its adoption by the Presiding Officer of the Semi-Annual Meeting next following the closure of the vote. [Any changes in the order of consecutive numbering of existing articles of the Constitution, made necessary by such adopted amendment, shall be made under the direction of the Council.]

A LOOK AHEAD

A Review of the Prospective Work of the Society for the Coming Year

HUNDREDS of calls are coming to the engineering societies of the country for help and coöperation in meeting the needs of the war. Highly-trained men are wanted in large numbers, besides technical advice and information on innumerable subjects. In all such work concerted action is necessary and the avoidance of duplication; hence the importance of the Engineering Council and its War Committees, representing collectively the several engineering societies as described by President Hollis, Chairman of the Council, elsewhere in this number.

In a look ahead the greatest promise for effective service to the Government by the Society appears to lie in the part which it will play in this united service by the engineers of the country.

Acting as a separate unit, however, the Society has already done enormous work in this direction largely through its Engineering Resources Committee, George J. Foran, Chairman, which has classified and indexed with respect to their specialties 4000 members and hopes eventually to have similar data for every member to use in supplying the war needs of the country.

DEVELOPMENT OF THE SECTIONS

Last year five new sections were organized at Baltimore, Detroit, Erie, Indianapolis and New Orleans, making a total of 21 sections. The Committee on Sections recognizes that these local organizations emphasize the national scope of the Society and intends to continue this development by the addition of several new sections besides the organization of the Connecticut Section with its five branches, announcement of which has already been made.

This organization of state sections is of more than passing interest. The Minnesota Section was the first and the Atlanta Section has aimed to administer to the requirements of several of the Southeastern group of states, but Connecticut is the first state to have a number of Branches holding meetings in their respective localities, and all contributing in addition to the development of the Society throughout the state. The plan of organization is explained more in detail under another heading.

It is the purpose of the Sections Committee to encourage the sections to identify themselves with local, civic and municipal affairs inasmuch as they relate to engineering projects. An effort will also be made to obtain united action by the several sections on work proposed by the various standing committees of the Society: as for example, if the Research Committee were to outline a series of investigations it is thought that they would be much more successful if the local sections joined in the conduct of the work.

The sections benefit the membership at large by the publication of the section papers in THE JOURNAL. The committee has therefore suggested as a uniform practice that each local section make a special effort this year to contribute technical papers and data, through the establishment of the following organization:

1. The appointment of a committee of three, particularly qualified, to study the local field and determine what papers and data the section is best qualified to contribute; solicit the contributions of papers from local engineers and report to the Committee on Sections. Attention is called to the fact that papers need not be long. In fact, brief, concise statements of valuable information often are of interest and value.
2. Select a committee of two, qualified by broadness of vision, to investigate what researches may be most effectively carried out because of the particular engineering work being done in the locality. Appoint those particularly fitted to organize and conduct these researches and report the findings to the Committee on Sections.

   These researches need not necessarily be in the nature of obtaining original data but may be reports of progress or achievements made in any branch of the profession or consist in the arrangement in convenient form of the best information available on any particular subject. Good technical reports on local engineering developments will also be excellent material.

   There are many well-qualified young men in each locality who will be glad to undertake to accomplish the results if properly encouraged.

It has been suggested that this organization be effected at once in order that one of the first meetings this fall may be given over to the promotion of these results.

In accord with the plan previously announced to have the sections brought into closer contact with the activities of the Society, the Committee on Sections will visit the St. Louis, Milwaukee, Chicago and Detroit Sections this month for the purpose of acquainting those sections with the needs of the Society as outlined in the preceding paragraphs.

In connection with the work of the sections it is pleasing to note that the members at Seattle, Wash., and Portland, Ore., have invited President Hollis to visit them, and for the first time in the history of the Society the members of the Society in those Northwestern cities will come together at a meeting held under its auspices. This will indeed be a momentous occasion and it is fitting that the President of the Society should be the guest of honor. It would not be surprising should the organization of a section in that locality result because of the spirit and enthusiasm which Dr. Hollis brings to all those who have the opportunity of hearing him promulgate his doctrines on the opportunity of the engineering profession to take a leading part in making the world a democracy.

MEMBERSHIP WORK

The work of the sections is closely allied to that of the Committee on Increase of Membership because it is the latter which often makes possible the establishment of a section by securing the strength in numbers to make possible successful meetings. The committee plans to continue during the coming year its established policy of conservatively encouraging the members of the Society to bring within the pale of its influence all mechanical engineers of proven ability and to continue the acquaintanceship work at meetings which it has conducted in the past. The present membership is over 8200.

STANDING COMMITTEES

The Finance Committee has prepared its budget for 1917-18, including a report for the past year, showing that the annual income has passed the $200,000 mark. Next year it is estimated to reach $228,500. In preparing the budget the usual plan is followed of providing for only 90 per cent of the expected income and for half of the initiation fees to be placed in the reserve fund. As a result of this sound policy, the Society holds an enviable position among other organizations as one of unquestioned strength and stability and prepared for any call upon its resources which is likely to arise.

The Committee on Meetings, which has conducted in the past year what are generally considered to have been the two most successful conventions of the Society, has plans well developed for the coming Annual Meeting, elsewhere outlined. Of the sub-committees, the Committee on the Protection of Industrial Workers has now under preparation a number of safety codes including codes for elevators, machine-shop guards and woodworking-machinery guards, which they hope to bring before the Annual Meeting in December.

The Publication Committee has rounded out the year with The Journal covering the mechanical engineering field through its reports of meetings of the Society and reviewing the engineering press more thoroughly than ever before. New departments have been added, the circulation is now considerably above 10,000 and the advertising is constantly increasing. While no radical changes are expected, it is intended to maintain this substantial development and growth; and this applies as well to the annual volume of Transactions and the annual volume of Condensed Catalogues.

The House Committee has completed extensive alterations in the Society's rooms. By the removal of partitions better facilities have been provided, the most modern lighting system has been installed, the acoustics have had most careful attention. The office is now located in two large rooms, one devoted to the publication and engineering work and the other to the business and secretarial departments. Later the reception and reading rooms, the Secretary's office and the Council room will be redecorated.

The Committee on Constitution and By-Laws has had under consideration for some time a number of amendments necessitated by the growing membership of the Society and the larger demands by other societies and the Government upon its facilities. A complete report of these amendments will be found in another part of this issue of The Journal.

TECHNICAL COMMITTEES

The Standardization Committee expects to continue its work in connection with the American Engineering Standards Committee. This committee has drawn up a constitution, and deems this to be only the beginning of what is hoped will eventually fill a very important national and international need. It is expected that with time there will be found to participate in the work of this committee every technical association or society whether of an engineering or other nature, not only in the United States, but abroad. A beginning in this direction has already been made in that the British Engineering Standards Committee has invited this American Engineering Standards Committee to send delegates to London to consider a change in the British standard Whitworth thread to the simpler cross section of the United States screw thread and to consider also the question of metric threads.

The Boiler Code Committee has the following program under consideration for the coming year:

The completion of the first revision of the Boiler Code, in pursuance to a recommendation which was accepted by the Council of the Society and which was as follows:

"Your Committee recommends that you appoint a permanent committee to make such revisions as may be found desirable in these Rules, and to modify them as the state of the art advances, and that such committee should hold meetings at least once in two years at which all interested parties may be heard."

The regular monthly meetings of the committee will be held for the purpose of considering communications relative to the Boiler Code and rendering interpretations thereon.

The Committee on Flanges and Pipe Fittings has the following topics: A 50-lb. low-pressure standard for steam, water and air, etc.; a 600-lb. standard for superheated steam; 800, 1200 and 3000-lb. standard for water, air, gas, etc., with ratings proportionate to shock or no shock conditions. Malleable iron pipe fittings and unions are also scheduled for the Committee's consideration.

The A.S.M.E. and the Manufacturing Standardization Committee have been working jointly in the compilation of drawings, tables and data, most of which should be available for the committee's discussion during the coming years.

The Research Committee has several sub-committees which have investigations or reports in process, outlined in what follows.

Lubrication: Research on cylinder lubrication under both steam and gas engine conditions is expected to be undertaken by Professor Flowers of Ohio State University. This

would call for an appropriation of $600 for the ensuing year to carry it through. The apparatus has been especially built for the purpose and is the only one of its kind in this country.

Cutting Action on Machine Tools: In conjunction with the Bureau of Standards, this committee is to carry out an investigation of the stresses and conditions involved by change of shape and material, cutting speed, etc., on a special planer equipped with a dynamometer at the Bureau of Standards. An investigation is also to be undertaken on the action of the De-Leeuw rotary cutter, which gives a very large increase in cutting capacity over the old type stationary tools, using the same materials. This work should prove very valuable from a production point of view and therefore would appear to be of considerable interest to the Government in connection with its munitions work.

Worm Gearing: This committee has prepared a study of the important American patents on the subject of bearing metals and expects to make a study during the following year of the foreign patents also. It has in view to collect all patent data before reporting; it will take at least a year to do this.

Flow Meters: This committee is preparing what is practically a complete text on the theory, formulae, accuracy, cost and desirability of various types of commercial flow meters now on the market. This is being written in six sections, at least two of which will be ready for publication in December.

The general plan upon which all of the sub-committees are working, is that all previous work upon the particular subjects involved should first be collected by means of a bibliography and written up in a compendium, so that reference outside of the report would not be needed. The principal reason for adopting this plan was to avoid the unnecessary duplication of work which so often occurs in committee activities.

Several of the other committees have standardization work under way upon which it is not possible to announce future plans at the present writing. So extensive has become the professional work of the active committees of the Society, however, that the Secretary has under advisement the organization of a department of the office staff to attend solely to the committe requirements.

THE ENGINEERING COUNCIL

THE formation of an Engineering Council is the outgrowth of a real need for proper consideration of questions of general interest to engineers and to the public, and to provide the means of united action upon questions of common concern. Many such questions have come up in the past and will arise in greater number in the future. This war has brought out very impressively the actual need for united action of some kind. At present the Council is concerned only with four societies because that seemed the most practical way of getting a group of men together to answer the immediate needs, but these societies do not assume to speak for all engineering societies in the country. Criticism that they are exclusive in any way is utterly mistaken. There is the hope that such a Council by proving itself effective may lead to much wider coöperation in a strictly representative body for all engineers, and thus pave the way for a very much larger union in the future.

How can the Council be enlarged? By a union of all societies either as the outgrowth of the present Council or by a congress of engineers leading to united action by all societies. The first method will be the most natural one because many local societies and national societies also have a large membership in the four societies at present concerned. We have three classes of engineers to reach: First, those who are members of local societies and not members of national societies; second, those who are members of national societies and not members of local societies; and third, those who are members of no society. The last-named class constitutes a very large number in our profession.

We engineers are almost as mixed as American citizenship, and we suffer therefrom just as much as America with a population representing every race and every people in Europe. There can be no question of the enormous advantage of union. That union should be completed by strengthening the existing agencies and not by the formation of new societies. The national societies are thoroughly national notwithstanding the occasional complaint that they are run by New York. If they have not been able to express the democratic spirit of our country as fully as might be desired, it is the fault of the members in all the states and not of the city in which the principal offices are located.

The four societies concerned at present are the American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers and the American Institute of Electrical Engineers. They have come together from time to time in the past for special purposes and there have been general conferences on subjects requiring immediate settlement, but until the Engineering Council was definitely organized in June there was no permanent body to advise all the societies. We have had many fruitful discussions in the past leading to useful action. The Standardization Committee which has been organized to represent five societies has passed upon commercial standards of all kinds. This committee has great possibilities and it should be enlarged enough so that its influence may become very widespread.

Many problems have already been presented before the Council. Its personnel, made up of twenty-four men representing equally the four societies, is well-balanced and judicial. The first duty was necessarily the organization and appointment of standing committees, which have already been reported in the press. They might with advantage be mentioned here:

1 Committee on Public Affairs, comprising Messrs. C. W. Baker, G. F. Swain, S. J. Jennings and E. W. Rice.

2 Committee on Rules, comprising Messrs. J. P. Channing, Clemens Herschel, N. A. Carle and D. S. Jacobus.

3 Committee on Finance, comprising Messrs. B. B. Thayer, I. E. Moultrop, Calvert Townley and Alex. C. Humphreys.

Certain questions relate, however, to the war and the assistance that engineers can render. A committee to be called the American Engineering Service Committee was appointed with instructions to invite the coöperation of all engineering societies. This committee in the first instance consists of A. D. Flinn of the Civil Engineers, A. S. McAllister of the Electrical Engineers, George J. Foran of the Mechanical Engineers, G. C. Stone of the Mining Engineers, and E. B. Sturgis of the Mining and Metallurgical Engineers. Its present duty is the tabulation and listing of the members of the five societies represented, in order that we, as a profession, may be in a position to take a larger part in the industries

after peace is declared. This tabulation has already in part been done, but in a rather unsystematical and unequal way. It is hoped that the new committee by having additions from other societies may make a final and lasting tabulation of all the engineers in the United States. The list is to be kept in the Engineering Building for general use in Government problems and in the industries. At present the committee is devoting its attention to the immediate need of the hour, namely, the procurement of men for special service in the Government. A list of specialists in the societies has already been completed.

There are three methods by which engineers may enter United States service: first, through some organization; second, through individual application to a department of the Government, and third, through selection by the Conscription Law. But this is war service wholly and not civil service, which is the same now as it has always been. As a matter of fact, a great many engineers have already entered through the engineering societies, through colleges and through various special boards in Washington. The importance, however, of a complete list of engineers and their professional specialties cannot be overrated. Such a complete list can be made only with the help of the local as well as the national societies. The committee mentioned above is organized with George J. Foran as chairman and A. S. McAllister as secretary. All societies should respond to the request for coöperation.

Another committee, of which Harold W. Buck is chairman, is called the War Committee of Technical Societies. The members are Messrs. H. W. Buck, A. M. Greene, Jr., R. N. Inglis, C. R. Corning, G. C. Stone, D. W. Brunton, J. M. Boyle, J. V. Davies, Joseph Bijur, A. S. McAllister, W. D. Richardson and Charles Baskerville. It was appointed to assist any organization in Washington, such as, for instance, the Council of National Defense, the National Research Council and the Naval Consulting Board, in any way in which it can bring to the attention of the engineers of the country the necessity for thought and help in the numerous problems that arise.

A Council organized by the enlargement of the present Engineering Council can be very effective in many ways without interfering with the autonomy of any individual society. Every society has some definite purpose of its own and also some which it holds in common with all other societies. One of the latter purposes relates to public service and to coöperation. To the end that all societies may understand fully their opportunity, the committee of which Mr. Foran is chairman has made a complete list of all the societies and their officers, and communications are being sent out inviting coöperation; and it is hoped that the Council may be successful in arousing sufficient interest to bring about a larger and better Council for all engineers.

In organizing the Council, provision was made for the election to membership of other national engineering and technical societies. There is no doubt that rules can be made under which these societies may become members, but this will involve consultation and discussion in the future.

The office of the Council is in the Engineering Societies Building, 29 West 39th Street, New York City.

(Signed) Ira N. Hollis, *Chairman*,
Worcester, Mass.

Calvert Townley, *Secretary*,
115 Broadway, New York City.

THE COMING ANNUAL MEETING

The time is past when engineers, citizens of a country at war, can with equanimity sit in convention to discuss details of engineering practice. Their thoughts are on the great problems of the war and on the service which they can render their country.

With this in mind the Committee on Meetings has planned a program for the Annual Meeting which is designed to be of definite and constructive value for those in the service of the Nation. While a sufficient number of excellent technical papers will be provided on general subjects to uphold the standard of the Society's Transactions for reference purposes, emphasis will be placed on a series of addresses to be given on some of the broad problems that now confront the engineer in his endeavor to give his country the mastery in the great struggle which is to make the "world safe for democracy."

On Tuesday evening will be an address by Hon. Wm. H. Taft, former President of the United States, and conferring of honorary membership on Maj.-Gen. Geo. W. Goethals, events of the greatest interest and satisfaction to every member.

The business meeting on Wednesday morning will be followed by a session in charge of the Committee on Local Sections. The importance which the Sections have assumed in the Society and the possibilities they offer for a broadening influence in the Society's affairs have led to the assignment of this as the opening session, and a very full discussion of the topics to be presented is hoped for.

An intimate account of the engineering achievements of the late Mr. E. D. Leavitt will be presented by Mr. F. W. Dean.

All are agreed that to win the war there must be conservation of resources, including food, fuels and supplies of all kinds; higher efficiency in industry and transportation; unlimited production of munitions and appliances of war; willing coöperation on the part of every citizen, regardless of his status in life; and the greatest possible development of American inventive and productive talent.

The question of the solution of such problems as the foregoing will form the basis of the keynote session on the general subject of Service of the Engineer to the Public. This session will last all day Thursday, December 6, and will be opened by President Hollis who will speak on Universal Public Service in Peace and War. He will be followed by other speakers treating of the topics given below:

The Agricultural Machinery Problem.
Topical Discussion on Machinery of Food Production.
Railroad Transportation.
Motor Transportation.
The Aircraft Problem.
Topical Discussion on Aviation.
Special Education in Time of War.
Engineering Research.
Building a Merchant Marine in a Hurry.

Certain of the foregoing subjects, notably Agricultural Machinery and Aviation, will be discussed in detail, with papers on steam, gas and electric power on the farm, farm transportation and the machinery of canning and preserving. In the case of the aircraft problem there will be discussed the

selection and training of aviators, and problems of aircraft engineering and aircraft production.

At the Cincinnati meeting last spring the three sessions on the principles involved in the manufacture of munitions were among the most enthusiastic and largely attended meetings ever held by the Society, with members in attendance from all sections of the country and Canada. In order to carry this work further a session has been arranged for the Annual Meeting by the Sub-Committee on Machine Shop Practice, upon the subject of inspection. At this session an attempt will be made to present, on the one hand, the requirements of the Government, and on the other, the difficulties encountered by manufacturers in interchangeable manufacture, with the object of defining as far as possible the philosophy of inspection and offering constructive suggestions for carrying out its underlying principles.

Two other sessions by sub-committees have been arranged, one by the Sub-Committee on Textiles and the other by the Sub-Committee on Air Machinery. The former, like the session on the subject of inspection, will deal with broad principles applicable alike to textile manufacture and to other lines of industry, two of the topics being questions of labor turnover and safety in textile mills.

Another timely subject under the present condition of affairs where manufacturers are working under tremendous pressure is that of industrial management and methods of increasing production. There will be a session on management at which one topic, a comparatively new one, will relate to the employment of women in the skilled industries, with special reference to machine-shop and heavy work. Bearing on this also will be addresses on the relation of industrial management to the engineer, to indicate the broadening field of the engineer and the extent to which his efforts must lie in the direction of the management of men, both in respect to efficiency and to social service. It is hoped that arrangements can be made for a luncheon for the membership on one day of the convention at which certain of these matters will be discussed in after-luncheon addresses.

It is expected further that Dr. Brashear will be with his friends of the Society again and deliver the lecture on the Beautiful in Commonplace Things which he was to have given last year, but was prevented from doing by his trip to the Orient. This lecture will be as an oasis in a desert in these war times when we are prone to forget that there are larger, higher and more important things in life than strife among nations.

As for the past two years, there will be a smoker on Wednesday evening for the membership and while the program has not been definitely concluded, several members have expressed the desire that Past-Presidents John R. Freeman, Ambrose Swasey and John A. Brashear may be prevailed upon to tell at that time some of the incidents of their trip to the Orient during the past year. Nothing, surely, could be more pleasing to everyone than this.

WAR CONVENTION OF AMERICAN BUSINESS

Chamber of Commerce of the United States of America, Atlantic City, N. J., September 17-21

THE program of the great convention of American business, just held at Atlantic City, was representative of all walks of life—cabinet officers, captains of industry, engineers, bank and railroad officers. Never has the Secretary attended a meeting from which emanated so impressive and vital a message for the engineers of the country who are holding the pivotal points on the firing line of industry. In some small measure the Secretary desires to pass on the message to every member of the Society.

The earnestness of the speakers and the seriousness of the situation in which the country finds itself at the present time were emphasized throughout the meeting. All the resources of the nation's business were whole-heartedly and unreservedly pledged to help win the war. *This includes us!*

It would be impossible to portray the fervor of the convention, and in the space available in THE JOURNAL no more than an outline can be given of the more important addresses. Those desiring a complete statement may obtain it in the next issue of *The Nation's Business*, published monthly by the Chamber of Commerce.

The addresses covered in the following notes are those of President Rhett, Secretary of War Baker, the Secretary of the Interior, Mr. Lane, and the Russian Ambassador, given Tuesday; those of President Bedford of the Standard Oil Co., Past President Harry A. Wheeler, Mr. Herbert C. Hoover, Mem.A.I.M.E., and Lord Northcliffe on Wednesday; and those of the Secretary of Labor, Mr. Wilson, and Mr. L. A. Osborne, Mem.Am.Soc.M.E., on Thursday.

The chairman of the Munitions Board, Mr. Frank A. Scott, Mem.Am.Soc.M.E., was absent on account of illness.

President Rhett said:

"The Chamber has not only called together the delegates from its own 950 commercial organizations' members, representing over 400,000 individuals, firms, and corporations, and its own individual and associate members numbering over 6000, but it has extended invitations to other commercial organizations of the country not members of the Chamber, to be represented here, and to unite with it in sending out a message from the business men of America which will let the world clearly understand that whatever the cost, whatever the sacrifice, they propose to place every resource at their command behind the Government, and its Allies in their determination to see that liberty, democracy, civilization, and humanity shall not perish.

"There may be those who would sacrifice any national welfare, present or future, to their own ambitions, possibly to their own comforts, but, thank God, in this splendid democracy of ours, they can constitute a very small minority, and in the ranks of business their number is negligible. Let us make this number infinitesimal by such vigorous pronouncements and by such united action both in convention assembled and in business engaged that every impulse to selfish or sordid action may be suppressed and a great wave of enthusiasm may move us on to such achievement in service and in sacrifice as shall constitute a compelling influence for a speedy conclusion to this war—a conclusion that will bring us a real peace—a peace for this generation and generations to come—a peace that will secure for all times to mankind its most precious possessions which in their aggregate we call civilization and humanity."

Secretary of War Baker struck the keynote of the conference when he declared at the morning session:

"American business has been at the right hand of the Government since the moment war was declared. We want every man that can be influenced by you, every woman, and every child enrolled in another great army, the army of American business."

Secretary Baker's speech was intensely human and forceful, and was so clear-cut and compelling that when he had finished he had given the big business men in attendance a clear idea of the reasons why business and the Government had at times been wide apart, and why they were now so closely welded together in a common cause.

Secretary Lane's speech was the feature of the afternoon session on Tuesday, and the audience, estimated at three thousand, cheered him again and again as he recounted the situation. Among other things he said:

"We of America, it is conceded, know how to make money, and we will prove that we know how to make war, wholehearted, resolute war, war that means organization, machinery, science, war that means men by the million and money by the billion, war that means heartbreakings, ruined hopes, a little glory perhaps, a certain self-respect, a world that men can grow in.

"If there is a danger in this country it is not that our men will not be brave, that our guns will not be great, that our troops will have no ammunition and our generals no strategy, but it will be the danger coming from discontent with domestic conditions. The business man can prove his loyalty most surely in fixing prices, in marking down the shoe lace, the loaf of bread, the hatchet, the coat, the beefsteak, all the commonplace things of life, than in any other way. There is not a business man in this hall who does not carry in his hand the future of this war."

The evening session was opened by an address by Charles Edward Russell, who was a member of the Root Commission recently returned from Russia.

He impressed his audience with the seriousness of the situation by emphasizing that

"A thin Russian line of soldiers is all that stands today between the Kaiser and his goal; all that stands between the principle of freedom and the triumph of autocracy. There are upon the Russian line from Rumania to Riga, 153 army divisions. Upon the entire French front there are only 123 German divisions. Let Russia collapse and the German flood will sweep aside anything of resistance that is now there. The Russian people are self governed and they look to us as their brothers. Instead of being bankrupt, they are the richest people on earth, richest in natural resources, richest in character.

"This is our opportunity to save the nation. Let us give freely. Let us show to them that we are really a United States and that we will fight for freedom to the end."

The Russian Ambassador, after a complete statement of conditions, exclaimed:

"What Russia needs most of all is improvement of railway transportation, reorganized agricultural production and a diligently executed possible restitution of supply of general commodities, whether manufactured within the country or imported. Railway materials of all kinds and primarily rolling stock machinery for repair; agricultural implements; machine tools, instruments and raw materials for improving the production within the country; certain commodities of everyday life, that is what Russia needs and needs badly. And, gentlemen, for these requrements to be fulfilled, outside of credits, she needs ships, ships and ships."

President Bedford of the Standard Oil Company urged both economy and increase of production, giving statistics to show the inadequacy of the present supply.

The most eloquent words of the entire convention was the peroration of Past-President Harry A. Wheeler, chairman of the Chamber's Committee on Transportation. He predicted federal control of railroads.

Thursday evening Herbert C. Hoover warned the nation of the penalty of failing to aid the Government, and that inability of business men to realize their responsibilities and coöperate adequately with the Government might result in socialism.

Speaking of Russia, he said:

"Justifiable as this revolution may have been and as great a cause of liberty as it may result, no one can deny that the whole trend of this revolution has been socialistic, and the latest phase is a development into practical socialism. The strain in the revolution, I am convinced from much experience in Russia, was the reaction from failure of the Government and the commercial classes to meet their public duty.

"The other end to be attained is of profound importance. The alternative to failure of our commercial system to maintain its place and at the same time serve public interest is rigid autocratic governmental organization of industry of the German type. Such organization is autocracy itself—it breeds beaurocracy and stifles initiative, and thus democracy, at its birth. We must organize—we must mobilize—our every national energy, if we are to win this war against the organization perfected by autocracy. Either we must organize from the top down or from the bottom up. One is autocracy itself—the other, democracy. If democracy cannot organize to accomplish its economic, as well as its military defense, it is a false faith and need be abandoned."

These are momentous words.

Lord Northcliffe, the head of the British mission, followed with a tribute to the ability and bravery of Mr. Hoover. He further prefaced his remarks by stating that he was engaged in directing one of the largest businesses in America, that of expending $50,000,000 per week.

He went into the exact details of the war as it pertains to us. The following is an example:

"You will require vast refrigerating stores for the preservation of meats and other foods for your armies. At this time six months from now you will probably have between 600,000 and 800,000 men in France. Think of the refrigeration machinery you must establish.

"This war is the greatest business the world ever knew and in our country we are doing nothing else. Let me tell you that you will have to furnish between five and six pairs of shoes a year in the easiest parts of the lines at the front and twelve pairs a year at the hard parts for each of the 600,000 or 800,000 men you will soon have on the front."

Lord Northcliffe pointed out that the average life of a rifle is six weeks as one instance in addition to those already cited of the amount of business organization that must be created in the United States on account of the war.

Thursday morning the third member of the Cabinet to address the meeting, Secretary Wilson, gave a condensed statement of why we were at war, and followed by an exhortation equally to the laboring man and to employers to remember that neither may take this opportunity of the nation's distress to gain advantages that could not be obtained in times of peace, and that the sole idea of all must be to coöperate to win the war.

On Friday the resolutions approved by the Resolution Committee and unanimously adopted by the convention were principally as follows:

"Assembled on the call of the Chamber of Commerce of the United States and representing more than half a million business men and every industry in every state in the Union, this convention promises to our people that business will do all in its power to prevent waste of men and material and will dedicate to the nation every facility it has developed and every financial resource it commands on such terms and under such circumstances as our Government shall determine to be just."

Next to the general pledge to the Government, the most important resolution was the second, which read, in part:

"Be it resolved by the representatives of American Business met in War Convention, that all war buying should be assembled under the control of one board or executive department; and

"Be it further resolved, that this war supply board or department should be given full power to procure war supplies to the best advantage to the Government as to price, quality, and deliv-

[illegible] a way to maintain essential industrial life without disturbing social and economic conditions, including the power to fix prices not only to the Government but to the public on essential products and to distribute output in a manner to promote the national defense and the maintenance of our industrial structure.

This proposal is one which the members of the chamber, particularly those of them who have had occasion to do war business in Washington, feel most strongly is essential to the effective prosecution of the war; and while there is variance of opinion as to the reasons for the present confusion, nearly everybody is agreed that centralization is the obvious remedy.

Another most important development which is only beginning—a very promising start has been made in some industries already—was the recommendation that every industry organize a war committee of its leading men to coöperate directly with the Government in finding a way to meet every demand that the Government makes on industry.

It will then be seen that this Society, "The Society of the Industries," is vitally affected by the decisions of this convention and as executives to carry them to a successful conclusion.

Calvin W. Rice.

Visit by the President

President Hollis will leave Worcester on October 14 for a visit to several Sections and Student Branches of the Society in the far West. His itinerary includes visits to the following cities: St. Louis, El Paso, Los Angeles, San Francisco, Seattle and Portland. Upon the completion of this trip Dr. Hollis will very nearly have accomplished his aim to visit every Section of the Society during his term of office, something which no other President of the Society has been able to do. Wherever Dr. Hollis has spoken, before Student Branches and Sections, he has been uniformly successful in creating unusual enthusiasm.

Including the visits made by the Secretary practically every Student Branch and Section of the Society, numbering 59 in all, will have been visited within the year ending November first.

The following table shows in detail what has been done, H indicating visits by President Hollis and R those made by Secretary Rice:

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER NOVEMBER 10, 1917

Below is the list of candidates who have filed applications for membership since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by November 10, 1917, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about December 15, 1917.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be somewhat slower than under normal conditions. The first step in the consideration of an application is taken by the Membership Committee, and this committee is composed of busy men, with limited opportunity to meet together in these strenuous times.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Alabama

APPLEBY, William C., Mechanical Engineer, Southern Wheel Co., Birmingham

JOHNSON, Morris R., Chief Field Engineer, Fairfield Works, Tennessee Coal, Iron & Railroad Co., Fairfield

Connecticut

CLARK, James G., Chief Inspector, Remington Arms Co., Bridgeport

HOGAN, William E., Superintendent Interior Transportation, Remington Arms U.M.C. Co., Bridgeport

LANE, AUGUSTUS H., Engineer,
The Eastern Machinery Co., New Haven
MEAD, RICHARD R., Assistant General Works Manager,
American Graphophone Co., Bridgeport
SPIERS, FREDERICK G., Superintendent,
B. & K. Mfg. Co., New Britain
WELLS, HERBERT E., Division Superintendent,
Remington Arms U.M.C. Co., Bridgeport

District of Columbia
BRIGGS, CLARK A., Associate Physicist,
Bureau of Standards, Washington

Georgia
ELEY, J. N., Consulting Mechanical and Electrical Engineer, Atlanta

NECROLOGY

ALFRED J. ORMSTON

Alfred J. Ormston, Jr., was born in Oil City, Pa., on July 6, 1883. He received his early education in the parochial and public schools and the private school of Dr. Samuel Earp, of Oil City.

For several years thereafter he was employed in the office of Alfred Smedley, chief engineer of the National Transit Co., in Oil City, in the capacity of clerk and stenographer, resigning to engage in business for himself in the production of oil.

He later entered Carnegie Institute of Technology, Pittsburgh, from which he was graduated in 1912, having completed the course in mechanical engineering. The following year he taught in the Institute, and later went to Watertown, N. Y., where he was employed by the Massey Machine Co. in the capacity of mechanical engineer. While with this firm he invented and took out letters patent on a small governor for engines. He assigned this patent to the Massey Machine Co., who now manufacture it as their "Type O."

From Watertown Mr. Ormston moved to Woodlawn, Pa., where he was employed by the Jones & Laughlin Steel Co. For a time he occupied the position of assistant master mechanic, and at the time of his death was assistant to Mr. C. L. Dudley, steam engineer.

On the afternoon of July 31 he was scalded by the discharge from a steam siphon at the works and died the following morning. Mr. Ormston became a junior member of the Society in 1913.

EDWIN D. TUCKER

Edwin D. Tucker was born in New York City on October 10, 1865. He was educated in the public schools of the city and in Wilson and Kellogg's private school.

Upon leaving school he served his apprenticeship with the firm of R. Hoe & Co., and later obtained his drawing-room and shop experience with the same firm. He was later promoted to the position of foreman, holding this until 1906.

In the same year Mr. Tucker became associated with Sheppard Knapp & Co. and was treasurer of the firm for five years, when he retired from active business.

He became a member of the Society in 1898. He was also a member of the General Society of Mechanics and Tradesmen, and of The Franklin Institute of Philadelphia. He died on July 9, 1917.

MYRON KNOX RODGERS

Myron K. Rodgers was born in November 1861. He was graduated from Washington and Jefferson College in 1886, taking the first prize in chemistry.

He left immediatey for the West, obtaining a position as rodman on the Montana Central Railroad, then building into Butte. He was rapidly promoted until he was made resident engineer, having charge of several tunnels. When this road was completed he obtained a position as surveyor with the Anaconda Copper Mining Co., and was advanced in a short while to the position of chief engineer, which he held until 1896.

At that time he became associated with Mr. Marcus Daly of New York, who was very much interested in mining. Mr. Rodgers became Mr. Daly's mining expert and traveled all over the world examining mining properties for him. In 1907 he went into the mining business for himself. He opened up the Nickel Plate Mine at Hedley, B. C., and also the Hidden Creek Mine of the Granby Co., taking both of these properties as mere prospects and developing them until they were ready for the reduction works. He designed and built the Hedley Gold Mining Company's mill. In 1912 he became interested in mining property in Mexico, but the revolution stopped any mining operations in that country.

He became a member of the Society in 1894. He died in June 1917.

SYDNEY FRANCIS SAVAGE

Sydney F. Savage was born in 1889 in Cambridge, Mass., and received his early education in that city. He was later graduated from Lowell Institute.

He was employed in an engineering capacity with manufacturing concerns in the vicinity of Boston, including the Blake-Knowles Steam Pump Works and the Hood Rubber Co., until 1914, when he entered the employ of the United Illuminating Co., New Havén, Conn., in the engineering department.

Upon the formation of the firm of Westcott & Mapes, New Haven, he joined the organization as mechanical engineer, later becoming director and assistant secretary and successfully directing many important undertakings.

He became a junior member of the Society in 1914. He died on August 18, 1917.

DWIGHT BOYCE PANGBURN

Dwight B. Pangburn was born in Washington, D. C., on Nov. 27, 1889. Later the family moved to New Haven, Conn., where he was educated in the public schools, being graduated from the high school in 1907. The same year he entered Yale University in the Sheffield Scientific School. He took the regular course in mechanical engineering, and was graduated in the class of 1910. He continued his studies in the same line until 1912, when he received the degree of mechanical engineer. He was then appointed an instructor in the mechanical engineering department in Sheffield and was holding that position at the time of his death.

Mr. Pangburn's shop experience was limited. However, during one summer vacation he acted as consulting engineer for the Hendee Manufacturing Company, and during the following college year he conducted some scientific tests of the Indian motorcycle for the company at Mason Laboratory, Sheffield.

He wrote many scientific articles for various publications, and also a number of short stories for popular magazines. He was a recognized authority on bird life and was a charter member of the New Haven Bird Club.

At the time of his death he was collaborating with Prof. Richard S. Kirby in writing a textbook on descriptive geometry.

He became a junior member of the Society in 1912. He was also a member of the National Geographic Society. He died on Aug. 24, 1917.

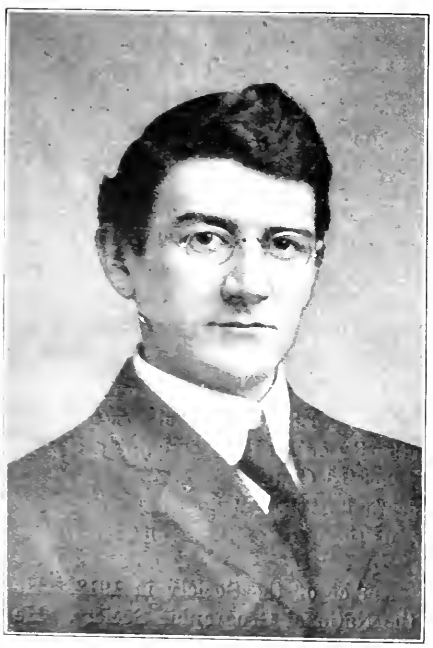
EXECUTIVE COMMITTEE OF THE LOCAL SECTIONS OF THE A.S.M.E. 1916-17

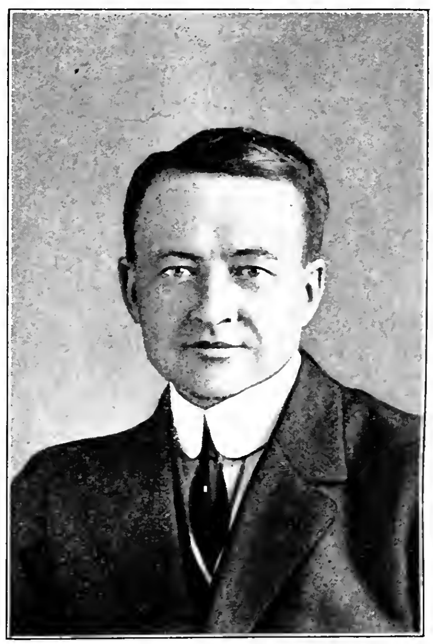
Elliott H. Whitlock

D. Robert Yarnall
Chairman



Walter Rautenstrauch

THE SECTIONS COMMITTEE HAS LAID OUT AN AMBITIOUS PROGRAM FOR THE SEASON. THE COMMITTEE WILL VISIT THE ST. LOUIS, MILWAUKEE, CHICAGO AND DETROIT SECTIONS THIS MONTH



L. C. Marburg

AMONG THE SECTIONS

IN another part of the Society Affairs Section of this issue of THE JOURNAL is given a very comprehensive statement of what the Committee on Sections expects to accomplish during the season just commencing. Of direct interest to the readers of THE JOURNAL is the plan to have each Section present two papers for publishing in these columns.

The President has just completed plans for a Western trip, of which the following is the itinerary: Leave Worcester October 14; St. Louis, October 16; El Paso, October 18; Los Angeles, October 22; San Francisco, October 26; Seattle, October 28 or 29. The Sections at the Coast are looking forward with a great deal of anticipation to this visit, especially as Dr. Hollis will be accompanied by Mrs. Hollis.

The Executive Committees of all the Sections have been actively at work during the summer on their programs, and by the end of this month a few of the Sections will already be holding their initial meetings. In the November issue we hope to be able to publish the programs for the season of all the Society's twenty-two sections.

The Providence Engineering Society, affiliated with our Society, held its opening meeting on September 18. A representative of the A.S.M.E. was present who prepared an account of the meeting which is published elsewhere in this issue.

EXECUTIVE COMMITTEES OF THE SECTIONS

Atlanta

OSCAR ELSAS, *Chairman;* CECIL P. POOLE, *Secretary;* EARL F. SCOTT, ROBERT GREGG, J. N. G. NESBIT.

Baltimore

W. W. VARNEY, *Chairman;* L. B. ROBERTSON, A. G. CHRISTIE, C. C. THOMAS, W. M. CHATARD.

Birmingham

J. H. KLINCK, *Chairman;* W. P. CAINE, *Vice-Chairman;* J. G. HATMAN, *Secy-Treas.;* PAUL WRIGHT, R. E. BRAKEMAN.

Boston

A. C. ASHTON, *Chairman;* W. G. STARKWEATHER, *Secretary;* RICHARD H. RICE, W. W. CROSBY, FRANK L. FAIRBANKS.

Buffalo

Committee to be appointed.

Chicago

ALEX. D. BAILEY, *Chairman;* H. T. BENTLEY, *Vice-Chairman;* A. L. RICE, *Secretary;* P. N. ENGEL, G. R. BRANDON.

Cincinnati

Committee to be appointed.

Detroit

GEORGE W. BISSELL, *Chairman;* S. J. HOEXTER, *Secretary;* T. H. HINCHMAN, E. C. FISHER, RUSSELL HUFF.

Erie

Chairman to be appointed; M. W. SHERWOOD, *Vice-Chairman;* R. CONRADER, *Treasurer;* M. E. SMITH, *Secretary;* N. A. NEWTON.

Indianapolis

W. H. INSLEY, *Chairman;* L. M. WAINWRIGHT, *Vice-Chairman;* B. G. MERING, *Treasurer;* F. C. WAGNER, L. W. WALLACE.

Los Angeles

F. G. PEASE, *Chairman;* T. J. ROYER, *Secretary;* RALPH SPRADO, H. L. DOOLITTLE, H. E. BRETT.

Milwaukee

W. M. WHITE, *Chairman;* FRED H. DORNER, *Secretary;* L. E. STROTHMAN, EDWARD HUTCHENS, M. A. BECK.

Minnesota

H. LEROY BRINK, *Chairman;* J. A. TEACH, *Vice-Chairman;* E. A. WILHELM, *Secy-Treas.;* J. V. MARTENS, C. W. TURBY.

New Haven

H. B. SARGENT, *Chairman;* E. H. LOCKWOOD, *Secretary;* F. L. MACKINTOSH, J. A. NORCROSS, J. W. ROE.

New Orleans

H. L. HUTSON, *Chairman;* E. W. CARR, *Secretary;* W. B. GREGORY, A. M. LOCKETT, R. T. BURWELL.

New York

J. J. SWAN, E. J. PRINDLE, A. D. BLAKE, J. H. NORRIS, W. H. GREUL.

Ontario

R. W. ANGUS, *Chairman;* CHESTER B. HAMILTON, JR., *Secretary;* C. R. BURT, L. H. FLETEMEYER, G. V. AHARA.

Philadelphia

L. F. MOODY, *Chairman;* JOHN P. MUDD, *Secretary;* EMMETT B. CARTER, W. R. JONES, H. B. TAYLOR.

St. Louis

R. L. RADCLIFFE, *Chairman;* E. H. TENNEY, *Secretary;* E. FLAD, W. A. HOFFMAN, H. R. SETZ.

San Francisco

B. F. RABER, *Chairman;* A. C. PAULSMEIER, *Vice-Chairman;* C. H. DELANY, *Secretary;* ELY HUTCHINSON, OMAR DENNY.

Worcester

GEO. I. ROCKWOOD, *Chairman;* R. G. WILLIAMS, *Secretary;* V. E. EDWARDS, H. P. FAIRFIELD, F. W. PARKS.

Providence Engineering Society

ROBERT W. ADAMS, *President;* GEORGE A. CARPENTER, *First Vice-President;* WAYLAND T. ROBERTSON, *Second Vice-President;* JOHN T. FRANKENBERG, *Third Vice-President;* WILLIAM A. KENNEDY, *Secretary;* and ALBERT E. THORNLEY, *Treasurer.*

Providence Engineering Society

The Providence Engineering Society can survey the work accomplished since its organization a year ago with just pride and satisfaction. The slogan of the organization, "Ideas + work = Results," has been productive of a very attractive group of meeting rooms, located on the top floor of the Rhode Island School of Design, conveniently located at 29 Waterman Street, Providence.

The first meeting of the season was held on Tuesday evening, September 18, at which Prof. J. Ansel Brooks, Past President of the P. E. S., gave an illustrated talk on My Trip to Honolulu. Professor Brooks spent about six months in the Hawaiian Islands last winter and spring, and secured a wonderful collection of photographs of the features of the Islands. Mr. John R. Freeman, Past President of the A.S.M.E., who visited the Hawaiian Islands en route to the Orient, was present and gave an interesting supplement to Professor Brooks's address.

The organization of the Providence Engineering Society embraces the following ten sections: Chemical, Dr. R. L. Lyons, Chairman; Designers and Draftsmen, Benjamin F. Waterman, Chairman; Efficiency, Howard D. Wilson, Chairman; Fire Insurance Engineers, Paul A. Colwell, Chairman; Industrial Education, Professor William H. Kenerson, Chairman; Machine Shop, Arthur H. Annan, Chairman; Municipal Engineering, Karl R. Kennison, Chairman; Power, Warren B. Lewis, Chairman; Structural, Eugene B. Whipple, Chairman; and Student, George R. Sturtevant.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

GOVERNMENT REQUESTS

The Society has been asked to make suggestions of men for the following positions with the Government. Further information will be given on request. Non-members of the Society having the qualifications may avail themselves of these notices by enclosing with their reply a personal introduction to the Society.

INSPECTORS OF STEEL HELMETS (under Civil Service Commission)

(A) Steel welding and rolling. Two or three men will be needed. The inspection of processes covers the operation of rolling into sheets and the incidental welding.

(B) Pressing. Six men are needed. This is the ordinary operation of pressed metal work.

(C) Assembling. Four to six men are needed. These men will inspect assembling, including the addition of incidental hardware and the lining, and will be responsible for the finished articles.

(D) In addition, at least six men will be needed to inspect the helmet linings, which are made of felt and leather, sewed by machine. Men of shoe experience to be utilized here. 2174.

RATE SETTER IN ARTILLERY AMMUNITION DEPARTMENT with at least one or two years' experience or more at assembly work, or a man clever with his hands in order that he may jump in and do each operation himself with dispatch, and tabulate his results in a neat manner, thus giving an indication of how many pieces an hour can be done in the various operations of assembling artillery ammunition. The man should not be influenced either by workers or by foremen, and will report results directly to the officer in charge. The work covers a wide range—from small primer work to handling of 6.2 shells. Such a man would be paid at the rate of $0.50 per hour. 2182.

INSPECTORS OF ORDNANCE EQUIPMENT (under Civil Service Commission). Inspectors for hardware and metal equipment, comprising such articles as buckets, rings, fasteners, hand axes, wire cutters, intrenching tools, canteens, cups, meat cans, cutlery and other small articles of brass, iron, steel or aluminum. Men who have had a high-school or equivalent education and in addition have had four years' experience in a manufacturing plant making such articles as those described above will qualify for one class of inspectors. Another class are graduates from a college or university of recognized standing and who have had one year's experience in a manufacturing plant, on the practical end of the work. These men should be over 25 years of age. Duties will consist in the organization and supervision of the inspection work in plants where equipment as described above is being manufactured. Inspectors will also be responsible for the preparation of the necessary reports covering the inspection, shipment and payment for the articles described. 2195.

MECHANICAL DRAFTSMEN who have been called by the selective draft, may, if they desire, serve their country in their chosen profession by being transferred from their respective cantonments into the drafting force of the Ordnance Department as non-commissioned officers. For further particulars, address Gun Division, Ordnance Department 1330 F Street, Washington, D. C. 2223.

MECHANICAL DRAFTSMEN WANTED IMMEDIATELY by the Gun Division, Ordnance Department, Washington, D. C. For further information, communicate at once with the Gun Division, Office of the Chief of Ordnance, 1330 F Street, Washington, D. C. 2224.

For the following positions, Nos. 2171, 2187 and 2217, letters showing qualifications should be sent to the Secretary. Further information cannot be given at this time.

MECHANICAL DRAFTSMEN AND MECHANICAL ENGINEERS. [illegible] to serve as civilians at salaries of from $1400 to $1800 per year. Later to be commissioned as First or Second Lieutenant at from $1800 to $2000 per year. 2171.

INSPECTORS OF INSTRUMENTS, division of Signal Corps. Men not subject to draft and with technical training preferred, especially in physics. Not necessary to have thorough knowledge of aeronautical instruments. Manufacturing experience of value. Salaries from $1200 to $2200 per year. 2187.

TECHNICAL GRADUATES OF ESTABLISHED UNIVERSITIES WITH DEGREE OF M.E.

(A) Some technical and executive experience in operating industrial plants, for commissioned service with salaries ranging from $2500 to $3000.

(B) Men of principally technical and some special experience in designing and coördinating work for the manufacture of products similar to military and naval ordnance, aeronautical supplies, internal-combustion engines, for commissioned service with salaries ranging from $2500 to $3000. 2217.

POSITIONS AVAILABLE

In forwarding applications, stamps should be enclosed for transmittal to advertisers; applications for non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society. Copy for notices must be in hand by the 15th of the month.

INDUSTRIAL ENGINEER—COST ACCOUNTANT. A well-established firm can offer exceptional opportunities for effective and interesting work to engineering graduates who have had substantial experience with modern industrial accounting, with special preference to manufacturing costs. In reply state age, education, experience, present and expected salary. 431.

ASSISTANT DESIGNER AND WORKS MANAGER. High-grade company with factory located in western Maryland desires services of a man having a technical training in the foregoing capacity. Duties: To assist in designing special machinery and developing ideas; analyze machine operations, prescribe equipment and devise means to effect speedy and economical production; superintend the manufacturing of such machinery. Requires the ability of a thoroughly practical master mechanic with original ideas as to methods, a knowledge of modern shop practice, familiarity with the design and application of time-saving fixtures, executive ability and diplomacy necessary to successfully direct a manufacturing plant. No question of salary if the right man applies. State full particulars and experience from technical degree, with the assurance that such information will be held as confidential and no investigation will be made with present employer prior to conference. 958.

SUPERINTENDENT AND FOREMAN OF POWER PLANT. Man capable of taking complete charge of large smelter plant consisting of steam turbines, large blowing engines, large rotary blowers, Diesel engines, waste-heat and oil-fired boilers, pumping plant, high- and low-tension electrical equipment, etc. Must be familiar with combustion and operating problems and have organizing and executive ability. Salary about $2,500. Location Arizona. 1025.

RESEARCH—TESTS ENGINEER. Man with mechanical and electrical training, from 28-35 years of age, preferably over draft age, for work in the standardization of household equipment. Location New York. 1082.

MACHINE DESIGNER between 25 and 35 years of age, with mechanical and electrical engineering knowledge and sufficient shop experience to enable him to design apparatus so that it can be economically manufactured. Some pneumatic engineering experience preferred, but not absolutely necessary. Work: Improvement of present product in regard to increasing the quality of finished article. Design of new products now in process of development. Salary, $1,200 to $3,600, depending entirely on man. Location Hoboken, N. J. 1155.

SHOP SUPERINTENDENT for machine shop manufacturing planers, lathes, etc., and employing 200 to 300 people. Confidential. 1158.

COMPETENT MAN to take hold of maintenance and machine repairs and general shop economies. Prefer one about 35 years old.

with technical education and enough shop experience to understand the operation of all machine tools, and with a full appreciation of the value of time on an operation without going into any efficiency work. Opportunity for advancement and eventually an executive position. Location Ohio. 1166.

SALESMAN for mechanical apparatus. Salary depends upon the man. Location New York State. 1167.

EXPERIENCED SALES-ENGINEER FOR FRANCE desired by export house. Man who has actually sold machinery in that country. Must be competent to develop efficient sales organization, appoint sub-agents, etc. A substantial profit share will be paid in addition to salary, therefore exceptional opportunity. Address applications in French or English. 1173.

MECHANICAL ENGINEER familiar with general machinery in wood-working and machine shop to take charge of drafting room. At present planning ship ways, and the work for this particular engineer will be the laying out of the wood-working and machine shop, as well as derricks, cranes, etc. Location Pennsylvania. 1175.

PRODUCTION MANAGER. Man 31 to 40 years of age, with machine shop experience and familiar with modern production methods, for a permanent position in charge of planning production department of a large manufacturing concern. In first letter state qualifications fully and initial salary expected. Location New York State. 1176.

INSPECTOR. Energetic, capable young man as inspector in plant manufacturing small machinery and machine parts. Should have had experience as a machinist. State initial salary expected, age, experience and qualifications. Good opportunity for advancement. Location New Jersey. 1183.

STEAM ENGINEER familiar with operation of boiler work, combustion problems, etc., for New York concern. Salary $150. 1184.

SALES ENGINEERS. Men at least 34 years of age, with college education or its equivalent, who have had mechanical training and shop experience, in the sales department of a prominent manufacturer of pneumatic machinery. Good opportunity for the right men. Give references, experience and salary expected. Location New York State. 1187.

DRAFTSMAN with sufficient experience to enable him to take charge of the making and checking of detail drawings in a drawing room employing two or three men. State qualifications and past experience fully. Large part of the work will consist of routine calculations; applicants must be possessed of technical training. Salary about $150 per month. Location New York State. 1189.

FACTORY EXECUTIVE technically trained, about 30-35 years of age, for large textile-machinery manufacturing plant. Knowledge of up-to-date shop methods essential, also successful experience in the handling of mechanics. Applicant would be required to spend from one to two years in shop to become familiar with the various classes of work, after which the position of assistant superintendent with further excellent opportunities for promotion will be open to him. Salary to start, about $2,500. Location Massachusetts. 1191.

CHIEF DRAFTSMAN with executive and engineering ability, competent to direct the work of eight draftsmen and superintend design of output of plant manufacturing large tankage, steel-mill buildings, zinc-smelter equipment and cement-mill work, along engineering lines. Must be competent to operate system now installed in relation to billing, routing and ordering materials. Want man with at least ten years' experience in manufacturing lines. Salary $2,000. Location Kansas. 2013.

HIGH-GRADE TOOL DESIGNER with good experience on heavy automatic-screw-machine tools including Acme, Gridley, Brown & Sharpe and Cleveland automatics, and also capable of handling the problem of standardizing tools and tool records. Salary $25 to $30 per week. Location Ohio. 2037.

TWO TECHNICAL GRADUATES approximately 30 to 38 years of age with experience of sufficient breadth so that they would be posted on problems of manufacture in more than one line. Men who have been steadied by experience, yet ambitious to push ahead and interested in the various problems of manufacture and construction. Location Massachusetts. 2071.

DRAFTSMEN for Watertown plant. Salary $20 weekly. Apply by letter to Employment Dept., Maxim Munitions Corporation. Derby, Conn. 2124.

INSTRUCTOR with technical and actual operating experience to take charge of stationary engineering department where exceptional opportunity along educational lines is offered. Location Pennsylvania. 2126.

CONSULTING ENGINEER in connection with sale and installation of swivel joints. Position would require man to travel quite extensively to call and confer with the master mechanic or engineer and see that our joints are properly installed. Position would be a dignified one and could be made very important, depending upon the results of the efforts put forth. Salary $50 per week and expenses. Location Wisconsin. 2133.

STRUCTURAL DRAFTSMEN (A) For Government work, two timber draftsmen, probably men familiar with trusses and trestles, and one general draftsman for general tracing and drafting. (B) Six structural-steel designing draftsmen and three or four draftsmen familiar with foundation work. Location Maryland. 2136.

METALLURGIST. Large manufacturer of automobile parts operating steel mill and tube mill desires services of a thoroughly competent metallurgist. An exceptionally good opportunity to secure position with firm having a nation-wide reputation for producing a high-quality product. Location Middle West. 2137.

SALESMAN. Young man of some experience to sell or promote patent rights on commission. Only part time will be needed. 2138.

ENGINEER with thorough technical training and not less than five years' experience, capable of designing installations of machinery, tanks, etc., estimating costs and supervising erection. Work in connection with new centrifugal processes. Position permanent. Location Eastern Pennsylvania. 2142.

INSTRUCTORS in mechanical engineering for university in Middle West. Salary $1,300. 2143.

TOOLMAKERS AND TOOL DESIGNERS experienced on jigs, fixtures and gages. Only first-class men need apply. Good salary and best of working conditions. Location Pennsylvania. 2155.

MECHANICAL ENGINEERS. Rapidly growing company has openings for trained and experienced technical men, also for younger men with technical training in mechanical engineering. Apply by letter giving training, experience, and class of work desired, whether operating, efficiency work, or designing. Location Pennsylvania. 2156.

DRAFTSMAN experienced in marine-engine, water-tube boiler and river-steamer work. State age, salary expected and references. Location Charleston, W. Va. 2157.

SUPERINTENDENT for electro-chemical plant. Man with experience and executive ability, capable of handling about 50 employees. Salary entirely dependent upon man. Location Pacific Coast. 2159.

SUPERINTENDENT with not less than five years' experience in factory management, to take charge of a factory employing 600 to 700 people; a man who is leader of men; who has had training as a mechanical engineer and if possible a designer of automatic machinery. Good opening for right kind of high-grade man. Confidential. 2160.

DRAFTSMEN experienced in power-plant work. College graduates preferred. Salary $125-$180, according to individual. Location New York. 2161.

DESIGNER of power-plant work. College graduate preferred. Salary $125-$180, according to man. Location New York. 2162.

MECHANICAL ENGINEER with originality and experience in supervising all details of engineering department. Must be capable and resourceful practical designer. Work of an industrial nature, covering smelting practice and coal- and ore-handling equipment. Large plant located in Eastern Pennsylvania. Salary $250 per month. Apply by letter. 2163.

YOUNG MAN not over 35 and not subject to military draft. Must possess some technical training or experience in mechanical lines, including drafting, be energetic and have executive ability. Salary to start, $1,300 to $1,500. Location New York State. 2166.

PRODUCTION MANAGER with experience in the manufacture of machine tools and specialty appliances. Location New England. Salary depends entirely upon individual. 2170.

SALES ENGINEER. Man competent in handling and selling reinforcing, bar steel, pig iron, coke, etc. Position requires man with some technical knowledge, preferably one with an engineering training and some practical experience in steel construction. Energetic and aggressive salesman of good character desired; one who will be loyal, and while anxious to advance, will not be disposed to fly from job to job. Salary about $4000. Location Pacific Coast. 2172.

DRAFTSMAN preferably one with some experience in general machine design and steel-plate work. Salary $75 to $90 per month. Good opportunity for advancement. Location Pennsylvania. 2173.

EXPERT IN CHECKING UP DRAWINGS to work on special machinery, coke ovens, etc. Salary up to $175 per month, depending upon individual. Location New York. 2175.

DESIGNERS. First-class men experienced on tools, fixtures and gages. State full experience. Location Illinois. 2176.

DESIGNER of regulators and a designer of tools. None but thoroughly experienced man need apply. Good opening with big manufacturing company. Location Middle West. 2177.

PHYSICISTS, CHEMISTS, ENGINEERS, DESIGNERS AND DRAFTSMEN for work of research, development, and design related to problems of telephonic, telegraphic and radio communication, which are matters of public importance. Opportunities for such men in both temporary and permanent positions. Apply by letter. Location New York. 2178.

ENGINEERS FOR STEEL PLANT. Four positions open in modern plant. Mechanical and civil engineering experience desirable. Salaries $125, $150, $175. Location Pennsylvania. 2183A.

MECHANICAL ENGINEER with some knowledge in installing and operating mining and ore-dressing machinery. Must be capable of starting and planning mining enterprises, and must study Russian if he does not already know it, and bring with him certain American agencies in the lines of mining machinery. Location Russia. 2183B.

PROFESSOR OF MACHINE DESIGN in mechanical engineering department of university in Middle West, to teach the subjects usually included under this title, with possibly some laboratory work on the strength and other physical properties of materials. Salary about $2500. 2184(1).

INSTRUCTOR IN MECHANICAL ENGINEERING, at $1400 to $1500, to teach a few hours of class-room work in elementary steam engineering and some elementary laboratory work, including gas-power laboratory. Prefer a man who desires to specialize in gas-power laboratory work. 2184(2).

TWO ASSISTANTS IN MECHANICAL ENGINEERING, at $850 for 9 months' work. One to have charge of the instrument room and the other to be assistant in office; both to do some correction of laboratory reports and class exercises. 2184(3).

SUPERINTENDENT OF AERONAUTICAL LABORATORY and its six or eight instructors in our School of Military Aeronautics. Should be a man of mechanical-engineering training who has specialized and has had considerable experience in the operation and testing of aeronautical engines, a good teacher, with executive ability in supervising and directing the work of the laboratory of 250 to 300 students. Such a man would receive at least $200 per month, 12 months in the year, indefinitely. 2184(4).

UNDERSTUDY to the superintendent of aeronautical laboratory called for in Position No. 2184(4). Would expect to pay from $150 to $175 per month. 2184(5).

DESIGNING DRAFTSMAN, man experienced on water-tube marine and stationary boilers and superheaters only need apply. Good position for competent man. State education and experience in detail, age and salary expected. Location New York. 2185.

YOUNG MEN wanted by manufacturers of mechanical instruments for indicating and reporting pressures, temperature, speed, etc. The position is ultimately that of traveling salesman with attractive pecuniary inducement. The start will be modest, as a course of training must be gone through at home office in New York. 2188.

INSTRUCTOR IN MECHANICAL DRAWING AND MACHINE DESIGN in the extension division of a university in the Middle West. Position consists in taking care of all correspondence study work in the above subjects and also in the revision and preparation of courses along this same line. Salary from $1500 to $1800 per year of 11 months. 2189.

YOUNG ENGINEERS with good technical education and from one to three years' experience along general mechanical-engineering lines. Must be of good personality, energetic, persevering and capable of considerable development; good opportunity for advancement. Address E. I. du Pont de Nemours & Co., Engineering Department, Wilmington, Del. 2192.

DESIGNER AND ASSISTANT OFFICE EXECUTIVE of power plant. Salary $150 to $175 per month. Location New York State. 2194.

AGENT FOR STEAM-BOILER AND FLYWHEEL INSURANCE. Applications will be treated confidentially from men who have demonstrated their ability to produce business in these lines. State fully experience and compensation desired. 2196.

YOUNG SALESMAN for New York City. Applicant should preferably have had experience in connection with building operations and must be a man of good address and pleasing personality. 2197.

TWO TECHNICAL MEN, one to act as a service engineer, the other as a sales engineer. The former need not necessarily be a technical graduate, but should be familiar with die design and hydraulic-press work. For the latter position desire a technical graduate familiar with automobile starting, lighting and ignition apparatus and electrical devices in general. Experience in plastic molding or die design would be advantageous. If applicants are between the ages of 21 and 31 they should show cause for exemption or have numbers near the end of the draft call. Prefer single men, since the positions will require considerable traveling over a wide territory. Product is highly specialized and the first two or three months of employment will be spent in the shop and laboratory. Salary commensurate with experience and ability. 2198.

DETAILER on interchangeable-parts machinery. Salary $25 to $35, depending upon individual. Location New York State. 2199.

CHIEF DRAFTSMAN, experienced on tools, jigs and fixture design, to take charge of a dozen men. Prefer man from 25 to 35 years of age with shop experience in the manufacture of interchangeable parts and with executive ability so that he can assist the superintendent directing the technical work. Salary $200 per month to start. 2200.

ASSISTING MANAGER for large chemical plant. Location New York State. 2203.

OFFICE EXECUTIVE to take charge of correspondence, routing of salesmen, agencies, etc., in connection with an industrial electric-truck manufacturing plant. State experience. Salary to start $2400. Appointment by letter. Location New York State. 2205.

YOUNG MECHANICAL ENGINEER, preferably a recent college graduate, to work up in engineering and steel export department, with probability of eventually taking charge. Location New York State. 2206.

DETAILER on hoisting and conveying. 2208.

YOUNG TECHNICAL GRADUATE as instructor in machine design in the mechanical engineering department of eastern college. Salary $1200. Work begins September 20. 2209.

TOOL DESIGNERS. First-class men for permanent positions. Location New Jersey. 2210.

DRAFTSMEN for power station of railway. Salary $100 to $150 a month. Location Ohio. 2211.

CONSTRUCTION SUPERINTENDENT on brick, iron and combustion. Single man preferred. Salary $175 to $200 a month. Location New York State. 2212.

EXPERIENCED DRAFTSMAN on jigs and fixtures. Good pay and opportunities. Location New York State. 2213.

INSTRUCTOR, with the rank of assistant professor, in engineering mechanics, strength of materials, materials testing laboratory, and hydraulics, for the University of Oklahoma, at Norman, Okla. Salary $1400 for year, with annual increase of $100. The position is for the duration of the war, possibly longer, as the school is growing rapidly. The man will have full charge of the work and be free to use his own methods and text. A teacher of considerable experience in these subjects might be paid more than the above salary. Recent graduates, preferably with some teaching experience, who intend to follow teaching as a profession, will be given careful consideration.

A similar position at the same pay and rank is open in the steam engineering and mechanical laboratory. This position is permanent. 2214.

MAN to assist in the design of laboratory of university in New England, later instructor in night course, to equip motor-vehicle laboratory for the experimental study of the factors entering into the construction and design of motor vehicles, including engine and chassis. 2215.

DETAILERS. Young engineers for work on specifications. Location New York State. 2216.

SUPERINTENDENT, preferably under 50, with enthusiasm and thoroughly conversant with shop routing, cost accounting, and ability for organizing. Position is available at once. Salary between $4000 and $5000 per year. Confidential. 2218.

DETAIL DRAFTSMAN, experienced on jig, fixture and tool designing. Salary $25-$28 per week. Also a man capable of taking charge of

the drafting room at salary depending upon applicant's qualifications. Location Connecticut. 2219.

FACTORY SUPERINTENDENT. Man thoroughly experienced in machine-shop practice and modern centralized planning-control methods; capable of securing large production in the most efficient, economical manner. Factory is divided into divisions of brass and iron foundry, structural steel, machine shop, pattern-making, wood work, polishing and plating. Product is light, generally concerned in the production of cash carriers, pneumatic-transmission tubes and light-duty conveying machinery. Location Massachusetts. 2220

MECHANICAL DRAFTSMEN having such experience in heating and general plant work as would regularly occur in the office practice of the average consulting heating engineer. Location Baltimore. 2221.

INSTRUCTOR IN MECHANICAL ENGINEERING to teach mechanical drawing and descriptive geometry in an engineering college on the Pacific Coast. Salary $1200 to $1400. 2222.

ASSISTANT OR ASSOCIATE PROFESSOR OF MECHANICAL ENGINEERING in charge of department, with salary of $1800 to $2000 for ten months, depending upon qualifications. These should include graduation from a technical school and both teaching and practical experience. Candidates should send without delay late photograph, full record of experience, and credentials. Location Idaho. 2225.

ELECTRICAL ENGINEER, with two or three years' experience developing automatic motor control for heavy machinery. Location near New York. 2226.

YOUNG MECHANICAL OR ELECTRICAL ENGINEER as assistant to executive in New York engineering office. Duties will be largely secretarial. Technical education and combined engineering and business experience are desirable. Salary $2000 to $2500. Apply by letter. 2228.

CHIEF DRAFTSMAN. Permanent position for chief mechanical draftsman with large firm manufacturing a number of heavy standard lines, boilers, engines, sawmill and pulpmill machinery, municipal machinery, etc. Location in city in Central Ontario, Canada. Apply by letter. 2229.

ADVERTISING MANAGER for large industrial corporation in New York City. Familiarity with advertising writing, printing, publishing, etc. 2230

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be in hand by the 15th of the month, and the form of the notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

EXECUTIVE position in the steel business—either in the manufacturing or sales end—desired by an American, technical graduate. Age 36, married. Fifteen years' experience in steel plant, general construction and varied engineering work. At present employed. Will arrange for New York interview. J-320.

CHIEF ENGINEER OR MASTER MECHANIC, now employed. Thorough technical and practical experience, covering the construction, operation and upkeep of steam and hydraulic power plants in connection with industrial works. Specialty: steam and fuel economy. Salary $2500. Available about October 1. J-321.

JUNIOR MEMBER, age 34, with 16 years' general engineering and operating experience, wishes position as malleable foundry engineer or superintendent in connection with engineering concern doing foundry work. Specialized in foundry equipment design, pattern making and mounting for multiple production, furnace operator, core making for agricultural-implement works and malleable pipe fittings. J-322.

SUPERINTENDENT OF POWER of steam-electric and compressor plant, age 31, married, technical graduate. Seven years' experience in design, construction and operation of steam-power plants and electric-transmission lines. At present superintendent of 10,000-hp. power plant for mining company in the Southwest. J-323.

MAINTENANCE ENGINEER OR SUPERINTENDENT OF POWER. Resigned from position as power and maintenance engineer of large industrial plant, and now available for position along similar lines. Have good general education, supplemented by special engineering and business courses of study. Four years of special machine-shop instruction; four years field erection and construction work on large engine, steam-turbine generators, refrigerating and structural machinery. Ten years with large western industrial plant as chief engineer of power plant and power and maintenance engineer. Have originality, training and experience to handle a big job where initiative and hard work will bring recognition and advancement. Non-user of tobacco and alcohol. Refer to former employers as to character and ability. J-324.

MECHANICAL ENGINEER. Technical graduate with experience in time-study, planning, production and inspection work, desires position of responsibility with manufacturing concern. J-325.

MECHANICAL ENGINEER—FACTORY EXECUTIVE. Graduate M.E. with 11 years' practical manufacturing experience. Has held positions as master mechanic, mechanical engineer and factory superintendent with large manufacturing company. Experienced in duplicate manufacture of light and medium-heavy machinery, also in woodworking from standing timber to highly finished cabinet wood. With present employers the past 11 years. Desires position with growing concern with opportunity to obtain financial interest. Middle West preferred. J-326.

MECHANICAL ENGINEER, 37 years old, with 18 years' practical experience with machine tools, steam turbines and engines, boilers and special machinery, exceptional theoretical knowledge, ability in design testing and operation, desires change. Also have had some sales experience. Location anywhere, but Middle West preferred. J-327.

MECHANICAL AND ELECTRICAL ENGINEER, age 34, married, technical graduate, 10 years' experience in power-plant design, appraisal and operation, also consulting and efficiency work in manufacturing. Can design, supervise or organize new work. At present employed, but desires new connections with ample opportunity to produce results. Salary, $3600. J-328.

EXECUTIVE OR WORKS MANAGER, age 34, married, technical, mechanical and electrical engineer with wide experience as executive manager and engineer; specialized in power-plant design and operation. Also experienced in industrial efficiency and appraisal work. Can furnish best of references. Salary $4000. J-329.

FACTORY EXECUTIVE. University graduate in mechanical engineering, 38 years old, wishes to make connections with modern concern manufacturing small mechanical or electrical apparatus in large quantities. Has thorough knowledge and practical experience in modern factory organization, manufacturing methods and employment matters. For several years connected as production manager and assistant factory manager with first-class concern employing 1800 men. J-330.

MECHANICAL ENGINEER OR SUPERINTENDENT. American, with 14 years' practical experience, also theoretical experience. Specialist in valves, fittings and engineering specialties of all descriptions; machines, tools, fixtures and equipment for same, shop maintenance; efficiency and production engineer. Successfully held positions and has references verifying above experience. J-331.

EXECUTIVE, ASSISTANT TO EXECUTIVE OR MECHANICAL ENGINEER. Cornell graduate, age 36, 12 years' experience in positions covering chief executive, office management and works manager, operation and construction and experimental work. Experienced in combustion, steam and gas power. At present employed. J-332.

SELLING ENGINEER, 27 years old, with 10 years' experience in power, gas and chemical equipment design and construction, desires position in sales work; has excellent business training; active worker with initiative and technical ability. J-333.

MECHANICAL ENGINEER OR CHIEF DRAFTSMAN. American, 41, with broad experience in meeting unusual conditions in collieries, smelters, chemical operations, etc. Can supervise work in shop or field. Salary $3000. New York district or foreign. J-334.

MASTER MECHANIC OR SUPERINTENDENT OF CONSTRUCTION. Technical education and 20 years' practical experience. J-335.

INSTRUCTOR in mechanical engineering, with five years' experience in drafting room, shop and laboratory, seeks extra work to be done in his office. Location New York City. J-336.

SALES ENGINEER, OFFICE EXECUTIVE OR DISTRICT MANAGER. Technical graduate, ten years' experience in eastern territory, highly successful in present work as a business getter, seeks larger field where energy and ability to show results are wanted. Nine years in present position. J-337.

PRACTICAL ENGINEER with broad tool-designing and machine-shop experience desires a responsible position where an agreeable personality, ability to handle men, an evening-school technical education, coupled with a capacity to "deliver the goods," will pave the way to a good future. For the past year and a half employed by a large ordnance firm to investigate their machine-shop methods and tools. Age 28, last numbers in draft. Salary $300 per month. J-338.

EXECUTIVE MANAGER. An executive of ability and aggressiveness, a mechanical, technical graduate, at present employed, desires to connect with a manufacturer whose business may need systematizing and building up as to organization and production. Has had a varied experience in different branches of manufacturing, operating industrial plants along lines of scientific management, and is fully conversant with modern methods of manufacturing and marketing product. Only

[illegible] position offering good possibilities for improvement. [illegible]

MECHANICAL ENGINEER [illegible] experience [illegible] with the 2000 [illegible] of elevating con[illegible]. Good organizer [illegible]. Lately re[illegible] country on account [illegible]. Will go anywhere if condition and salary are right. J-340.

CHIEF ENGINEER OF POWER PLANTS OR PLANTS AND SUPERINTENDENT OF GAS WORKS. Age 36, married. Assoc Mem Am Soc M E. [illegible] in present position. Holds Massachusetts [illegible]. Has had extensive experience on both General Electric and Allis-Chalmers turbines and different types of water [illegible] and almost all types of steam boilers at various pressures. [illegible] executive ability. Would consider a position in the [illegible] is preferred. Salary $5000. All correspondence will be treated confidentially. J-341.

TECHNICAL GRADUATE M. E., with two years' practical experience [illegible] engineering. At present employed as assistant to factory engineer of an industrial plant. Has had considerable experience in designing and construction work. Position in the East preferred. J-342.

PURCHASING ENGINEER. At present engaged with large corporation and in touch with production and export organizations; qualified as a [illegible] and [illegible] in machinery, metal products, machine tools, [illegible] equipment and engineering materials. Desires to change, assuming greater responsibilities and expecting commensurate salary. J-343.

DRAFTSMAN. Graduate mechanical engineer, age 24, with 18 months' experience in the design and layout of refrigerating plants and machinery, desires position, preferably in the East. Available on short notice. H-344.

COMBUSTION AND STEAM ENGINEER. Junior member, Cornell graduate, age 28, experienced in fuel and combustion engineering, testing boilers, engines and stokers and also cost distribution and operation, maintenance, construction and supervision of power-plant equipment supplying compressed air, steam, refrigeration and hot water and steam heat. Salary $2000. Location New York. J-345.

EMPLOYMENT MANAGER, at present employed in that capacity, wishes to make a change. Thoroughly competent to hire all classes of help, having had 18 years' practical mechanical experience. Age 37, married. J-346.

FACTORY EXECUTIVE, MASTER MECHANIC OR PLANT SUPERINTENDENT. Age 39. 18 years' experience as production superintendent in the manufacture of engines, condensers, high-vacuum air pumps, centrifugal pumps, etc. General engineering work, both medium and heavy. Has [illegible] extensively in connection with field work on same. [illegible] personality, alert and resourceful [illegible] judgment in all dealings and retaining confidence of organization. J-347.

MECHANICAL ENGINEER. Purdue graduate, age 29, married; experience [illegible] of design, construction, installation, purchasing [illegible] to buildings, machines and department [illegible] employed as supervisor over large drafting room. Salary $2000 to start. J-348.

EQUIPMENT ENGINEER, PRODUCTION MANAGER OR SUPERINTENDENT, with [illegible] knowledge of manufacturing methods and processes [illegible] to apply them to get the maximum production [illegible] men employed. J-349.

MECHANICAL ENGINEER OR ASSISTANT TO EXECUTIVE. [illegible] 25. Two years' experience in the manufacture [illegible]. At present employed. Salary $1800. Location New York City or vicinity. J-350.

ENGINEER OR CHIEF DRAFTSMAN. Technical graduate with 18 [illegible] assistant engineer. [illegible] design of centrifugal and [illegible] conveying machinery, shoe [illegible] making [illegible] power transmission, general factory equipment. [illegible] Salary $2500. Open for engagement Jan. 15. [illegible]

CONSULTING OR ADVISORY ENGINEER. Member with large [illegible] engineering experience on equipment, up[illegible] ways and means and industrial economies [illegible] desires to serve a few reliable manufacturing concerns in [illegible] advisory or designing capacity. J-352.

RAILROAD EQUIPMENT EXPERT. Age 33, college education. Several years' varied experience in designing, construction, estimating, [illegible] shop, office, executive on various types of railroad equipment, including buildings and power plants, foreign and domestic. Speaks foreign languages. Best of references. J-353.

MECHANICAL ENGINEER, EXECUTIVE. Age 31, married. Technical education with two years' commercial experience and six years as designer on steam turbines and power plant. Desires position as works engineer or assistant to executive in manufacturing or engineering firm. Excellent health and habits. J-354.

MECHANICAL ENGINEER. Associate member, age 30. Technical training: three years in civil engineering work, foundation, concrete, steel building and power-house erection; four years' mechanical engineering experience on boilers, engines, special apparatus, hydraulic machinery, shop work, producer-gas engines and generators, industrial plant work; two years in electrical work on a.c. and d.c. generation, transmission and distribution. Good executive. Desires to specialize. J-355.

PLANT ENGINEER OR ASSISTANT TO EXECUTIVE. University graduate, mechanical engineer, not liable for military service under present conscription law. Fourteen years' varied experience in engineering work and design; familiar with modern shop methods and follow-up; thoroughly practical, with executive ability; not afraid of work or responsibility. Desires to communicate with only those who intend to employ a competent assistant for a number of years. J-356.

EXECUTIVE MECHANICAL ENGINEER. Cornell graduate, age 35, married, fourteen years' practical experience in machine-tool use, manufacturing and commercial branches of business; trained in sales engineering and general management. Seeks responsible executive position as general manager or sales manager of progressive machinery manufacturer. J-357.

MECHANICAL ENGINEER with 15 years' experience in designing, estimating and general drafting in excavating machinery, hoisting engines, derricks and miscellaneous machinery, also some experience in machine shop and cast-steel foundry practice, desires a position as chief draftsman or assistant engineer with a concern where there is a good future. Now employed. Middle or Far West preferred. J-358.

ASSISTANT MECHANICAL ENGINEER, ASSISTANT MASTER MECHANIC, ASSISTANT TO MANAGER OR ASSISTANT TO EXPERIMENTAL ENGINEER. Member, born in Norway; age 42, technically educated, married; 21 years' designing and executive experience with large concerns. Has good sound judgment. Anticipates making a change and can go at a week's notice. Location New York or Brooklyn preferred. J-359.

INDUSTRIAL ENGINEER. Junior member, American, age 28, married. Six years' experience in all branches of manufacture of small parts with concern employing 3000 men in time-study work, planning, routing, estimating costs, etc. Experience in detail upon request. At present employed. Good executive ability proved. J-360.

MECHANICAL ENGINEER. Columbia graduate, 1912, with five years' experience in design, construction and inspection work with prominent concerns. Well grounded in machine design, plant layouts, and equipment. Desires position in engineering department, or as assistant to department head. Preference given to opening presenting chance to advance. J-361.

MECHANICAL ENGINEER. Columbia graduate, age 37, married. Fourteen years' service in motive-power department of large western railroad, in testing laboratory, as draftsman, assistant engineer of tests and assistant mechanical engineer. Desires opportunity for advancement and greater responsibility. At present employed. J-362.

TECHNICAL GRADUATE in mechanical engineering desires employment leading to a position in efficiency department. Experience has been mainly with mining machinery and jigs and fixtures. Has had experience in machine shop. J-363.

MECHANICAL ENGINEER. Stevens graduate, age 28, with five years' experience with Diesel engines and auxiliary machinery, desires position with more direct bearing upon the prosecution of the war than present position offers. J-364.

ASSISTANT TO EXECUTIVE. Young technically trained engineering draftsman, exempt from military service, desires a change. Experience covers general steel-mill engineering, construction and machine design. Location Chicago. J-365.

AERONAUTICAL MECHANICAL ENGINEER, age 28, three years' engine experience in aeronautics, also auto-engine experience. At present employed in Buffalo. Desires to enter the production field as production expert or inspector. J-366.

MANUFACTURING EXECUTIVE. Member, age 34, who is a technical graduate and has handled propositions in organization of gas, munitions and artificial silk properties, is now available. Salary $6000-$7200. Location immaterial. J-367.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and a Selected List of Engineering Articles

British Workshops and the War

In a speech delivered in the House of Commons, June 28, 1917, by Christopher Addison, then Minister of Munitions in the British Cabinet, it was stated that the program decided upon by the British Government in 1915, as regarded the production of munitions, required the erection of large additional factories in many lines. As a result of this policy, many products have been manufactured at a price considerably below that which prevailed in the market at the time of the erection of the factories. Thus the present cost of production of one of the basic high explosives, trinitrotoluol, at Queensferry, exclusive of interest and amortization, is 8½d. per lb. When the factory was started the cost in the market was 1s. 9d. per lb.

In connection with the manufacture of explosives and under an arrangement with the Food Production Department, a section of the Explosives Supply Department has been started for the provision of all the artificial fertilizers which are required. The control of the iron and steel industries gives all the basic slag that is wanted, and it is expected that the entire war problem in fertilizers will be met and give more than one million tons of superphosphates, nearly half a million tons of basic slag and a quarter million tons of sulphate of ammonia. Further, through the ingenuity of Mr. Kenneth Chance and his staff, a process has been discovered whereby great quantities of potash may be obtained sufficient to meet the requirements of the optical-glass trade and leave some surplus for the needs of agriculture.

The production of sulphuric acid has also been greatly increased. In particular, that of fuming acid is more than fifteen times greater than it was before the war and costs less to produce.

That the production of gun ammunition and fuses has been increased many times is a well-known fact. It is less well known that a new explosive component has been found and apparently thoroughly tested out.

Many of the filling and shell factories are worked by voluntary boards of management. At present the whole work of filling employs about 100,000 persons, and the cost of filling has been reduced by 40 per cent, as compared with what it was a year ago.

The inspection department has grown tremendously in the last two years, both because of the increasing magnitude of production and because of the greater diversity of the munitions supplied. In July, 1915, the staff of the inspection department consisted of 8761 persons. It now consists of nearly 40,000 persons in the United Kingdom, with an additional staff in the United States of more than 8000. An effort has been made to employ women in every possible way. In March, 1916, they composed 28 per cent of the staff. They now compose 61 per cent, numbering 29,000, and they are employed on almost all operations except those in which special technical experience or physical strength are required.

Notable improvements in design are claimed to have been made. During the Battle of the Somme reports were constantly received that a considerable number of rounds of ammunition either failed to explode or burst prematurely. This has been eliminated to a considerable extent.

As regards the development in gun supply, the demand for guns for anti-aircraft purposes and for the arming of merchant ships has placed a particularly heavy strain upon the country's capacity for producing long-range guns for use in the field. At the same time the output at Enfield has increased tenfold and the weekly capacity for the production of machine guns is more than twenty times greater than it was two years ago. Some months ago the output of small-arms ammunition became so abundant that it was found unnecessary to place any orders outside of the United Kingdom. The arsenal at Woolwich has increased tremendously. In August, 1914, the staff consisted of 10,866 persons. Now it amounts to 73,571. The number of women employed in 1914 was 125. Now it is close to 25,000.

A significant instance of how the war helped allied industries is cited in the case of glass for optical instruments. Before the war England would rely on home sources for only about 10 per cent of the glass used in optical instruments, being dependent mainly on German and Austrian supplies. Since the war, however, difficult formulæ have been worked out, especially by Professor Jackson and his colleagues, and under comprehensive arrangements England not only has adequate supplies for herself, but is able to provide substantial assistance to her allies. In fact, the whole group of industries connected with the glass trade has been placed on a secure foundation.

The great provider of the war industries, the machine-tool department, is the servant of all and has to furnish every variety of machine from the smallest tool, or lathe, to the mightiest crane. The department has a machine-tool clearing house by which idle and insufficiently used machinery is investigated and examined and an attempt made to divert it to better use. During the past seven months (previous to June, 1917), this branch investigated 22,027 applications and succeeded in releasing 42,638 machines roughly valued at more than £3,000,000.

The "tank" made its appearance last autumn. At the close of the year much work was still required to be done in the way of alterations and improvements, but the supplies of new designs are coming forward excellently. The end of the story is not reached and constant improvements are being made.

As regards aeroplanes, it had been found that the mobilization of all resources for the production of internal-combustion engines under a unified scheme of direction was essential. Such a working relation was established. Formerly there were a number of shops which were producing a number of different types of engines. By a continued effort to diminish the number of types and to concentrate on the best, with the policy of maintaining one shop devoted to the production of only a single type of engine, an enormous increase

in production has been obtained apart from the addition either of machinery or labor. The output of aeroplanes is rapidly increasing. The production for May is more than twice that of December and four times greater than that of May 1916. The supply, however, will become much greater still in a few months' time, for the government is working at a vast problem of production and the plans provide for its full realization.

The following statements are made as regards the effect of the submarine campaign on the production of munitions. In overseas supplies alone the Ministry of Munitions is interested in nearly 1,500,000 tons of munitions monthly. Of shell components shipped from North America to supplement home production the total loss since the commencement of the unrestricted submarine campaign, taking the heaviest item of

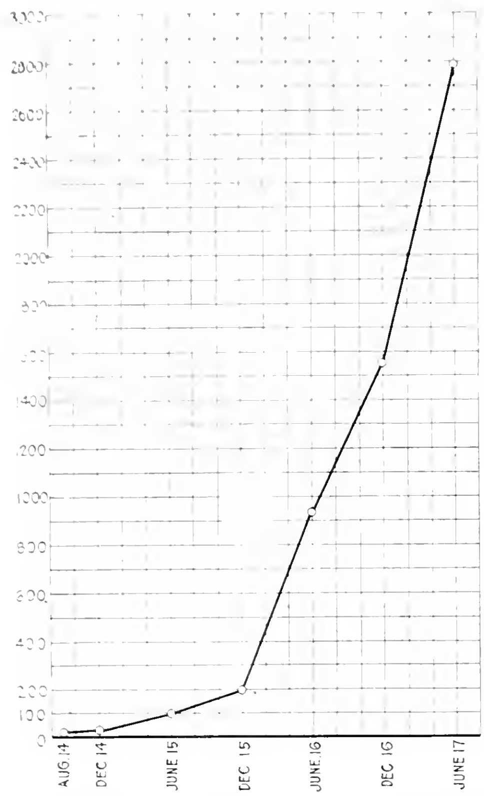


Fig. 1 Increase in Production of British Munitions, by Weight

loss in any single component, is only 5.9 per cent of the amount shipped.

As regards the American and Canadian supplies, it is stated that until recently all purchases were made through J. P. Morgan & Co. Lately, however, Mr. Gordon, the Vice-Chairman of the Imperial Munitions Board of Canada, at the request of the Minister of Munitions, has moved to the United States and has been appointed as the head of all British munitions organizations there and will report to Lord Northcliffe. Negotiations are now (June 1917) proceeding at the suggestion of the United States Government for a further consolidation of interests on both sides.

A vigorous attempt has been made to economize in the use of metals and a part of the program was the institution of scrap collection and distribution. For this purpose an extensive salvage department has been established, which works in coöperation with the armies at the front. The Minister of Munitions proposed to re-form hundreds of thousands of 18-pounder cartridge cases. When it is remembered that the price of a new case is about 7s., that it can be re-formed four times, and that the process of doing it costs 4d. a case, the importance of this branch is obvious. Another committee is charged with the duty of devising ways of economizing in the use of the more expensive metals. In this way a reduction in the amount of copper used in copper bands is secured, amounting to a saving of many thousands of tons of copper in a year, and less expensive metals are now brought into use as constituents of various fuses and other shell compounds.

A large amount of attention is being given to the question of health of munition workers, and principles are being established which will continue to be applied long after the war. More than 600 firms have appointed supervisors whose sole duty is to promote the welfare of their workers, and great benefit has resulted in different directions. Should they be necessary, schemes have been prepared in connection with the feeding of munition workers which have regard to the arduousness of the labor in which they are engaged. Last year the problem arising out of the handling of poisonous explosives (T.N.T. in particular) became somewhat acute, and a special committee was appointed to investigate them and make reports. This resulted in the application of suggestions which have been accompanied by an enormous diminution in the cases of illness. It has been found here, as in many cases before, that the problems of prevention when understood are simpler than those of cure.

The widespread employment of women in munition work has been accomplished with singularly little difficulty. From 60 to 80 per cent of the machine work on shells, fuses and trench-warfare supplies is now being performed by women. They have been trained in aeroplane manufacture, in gun work, and in almost every other branch of ammunition work. Also a large amount of mobile labor, not previously trained, has been utilized. For this purpose training supplementary to that which goes on in the works had to be resorted to. More than sixty technical schools and colleges in Great Britain are used in this work and have trained more than 32,000 workers. There are also five special industrial factories engaged in training. Three other sections of the Ministry of Munitions have been in constant operation to supplement that which is done either by dilution or training. There are 38,000 skilled work people employed away from their homes as war-munition volunteers and also 40,000 soldiers who have been released from the colors and have placed themselves at the disposal of the Ministry.

The Engineering Council has organized a committee known as the War Committee of Technical Societies. This committee is "to act as the intermediary or means of communication, when desired, in matters relating to Science, Research, Invention and Engineering" between the many and varied agencies of the Government and the membership of technical and engineering societies. It is hoped that by this means members of technical societies who as yet have not actively engaged in war work will allow their technical and engineering abilities to be drawn upon.

One of the first activities of the committee was to send to the membership of the technical societies the first bulletin issued by the Naval Consulting Board, under date of July 14, 1917, on The Submarine and Kindred Problems. Each member receiving the bulletin is urged to concentrate his best efforts upon the problem and to transmit any valuable ideas to the Secretary of the Naval Consulting Board.

U. S. BUREAU OF STANDARDS

THE U. S. Bureau of Standards is now doing work of exceptional interest and importance in connection with the war activities of the country. From time to time mention is made in the press of its new great laboratory for testing aircraft engines and of its work for the U. S. Army and Signal Corps. Of course, the greater part of this work is, as it should be, confidential.

But in addition to these special activities, the Bureau of Standards is carrying on many investigations of profound interest to the engineering profession. Thanks to the courtesy of Dr. S. W. Stratton, Director of the Bureau of Standards, and his staff of assistants and investigators, THE JOURNAL is enabled to present to its readers, beginning with the present issue, data on such of the work of the Bureau as is considered suitable for publication.

U. S. BUREAU OF STANDARDS

THE LATENT HEAT OF VAPORIZATION OF AMMONIA, Nathan S. Osborne and Milton S. Van Dusen

The latent heat of vaporization of liquid ammonia has been determined throughout the temperature interval —42 deg. to + 52 deg. cent. by direct measurements, using a calorimeter specially designed for the particular problem. This instrument is of the aneroid or unstirred type, the ammonia being the only liquid in the calorimeter. Heat developed and measured electrically in a coil is transmitted by conduction and convection to the ammonia, and is expended in the evaporation of a determined amount which is withdrawn as superheated vapor. Accessory data from other sources are required only in the computation of small correction terms. The results are expressed by an empirical equation and a table of values given for every degree from —45 deg. cent. to + 55 deg. cent. By combining the data for the heat of vaporization with the data for specific heat of the saturated liquid from a previous investigation, the specific heat of saturated ammonia vapor is obtained and a table of values of this quantity is given in an appendix.

CONSTITUTION OF PORTLAND CEMENT

In order to determine what new constituents are produced in portland cement when the magnesia content is raised considerably above that permitted by present standard specifications, and in order further to determine what effect these new constituents would have upon the physical properties of the material, a number of cements were burned in the rotary kiln of the Bureau. In these the magnesia content varied from 1.7 per cent to 25.5 per cent. In all 18 different cements were produced in two series of nine burnings each. In both series the compositions were those of normal cement, excepting the magnesia content only. But in one case the silica content was somewhat higher and the alumina content somewhat lower than in the other case.

As raw materials, clay, kaolin, feldspar, limestone and dolomite were used. In the one series the cement of lowest magnesia content was made of a raw mix containing limestone, clay and a small amount of feldspar, the latter being added to increase the silica-alumina ratio over that obtainable with clay and limestone alone. The magnesia in the other burns of this series was increased by replacing the limestone with dolomite. In the second series the raw mixes were composed of clay, limestone and a small amount of kaolin, the latter being used to decrease the silica-alumina ratio over that obtainable with the clay alone. In this series also increasing amounts of limestone were replaced with dolomite, until dolomite alone was used.

The deportment of the high-magnesia cements in the kiln was very characteristic. There was a reduction of the clinkering temperature with increasing magnesia content, though to produce satisfactory clinker this was not as marked as expected. But to prevent the dusting of the clinker of the higher-magnesia-content cements, it was necessary to overburn to a very hard vitreous mass. This mass in the kiln was about of the consistency of putty, and as a result there was a decided tendency to form "logs" and "rings." The clinker was also

of a reddish brown color, which gave a decided brownish tinge to the ground cement.

A microscopical examination of the clinker showed that increasing amounts of magnesia produced an increasing size of crystals and granularity. When the magnesia exceeded 8 per cent, a constituent (monticellite) not present in normal cement was noted. When the magnesia was still further increased to an amount exceeding 10 per cent, another constituent—spinel—not present in normal cement, was also noted. It was also noted that those constituents—tricalcium silicate and tricalcium aluminate—which produced quick setting and early strength, were not materially decreased by the appearance of the new constituents; whereas, the orthosilicate of lime which produces the later hardening and modifies the early setting of the other constituents, was decidedly decreased in amount.

The effect of the higher magnesia, when not exceeding 8 per cent, was not very noticeable in any of the physical properties. Higher amounts produced a quick initial set and an apparent slow final set. The strength both in tension and compression of neat and mortar specimens, and of concrete specimens in compression, when 8 per cent was not exceeded, was very comparable with the strengths exhibited by cements of normal magnesia content. Above these amounts the early strengths were less, but show a consistent gain with age.

Specimens are still available for examination and breaking at later periods than those reported in this paper.

Tests of Large Bridge Columns, H. H. Griffith and J. G. Bragg

The investigation gives a comparative analysis of the experimental data found upon eighteen large bridge columns when they were tested in the 10,000,000-lb. testing machine. The action of each column, as a whole, was studied in a range of loadings taken to determine the behavior of lattice bars, pin plates, diaphragms, etc. The causes and effects of initial strain from riveting and fabrication are discussed.

Technologic Paper No. 10 of the Bureau of Standards.

Paints and Varnishes

This publication is intended to give, without unnecessary detail, information which should be of value to those interested in the use of paint and varnish. After a general discussion and classification of paints and varnishes and an explanation of the process of "drying," the raw materials, including oils, driers, thinners, resins, and pigments that enter into the composition of paint or varnish are individually described. The methods of manufacture and of testing varnishes are presented, ready-mixed or prepared paints are discussed, and somewhat detailed instructions on mixing paints and stains, on color blending, and on the application of paint and varnish to various surfaces are given. Specifications in common use for many of the materials treated are included, and a glossary of painters' terms also appears.

Circular No. 69 of the Bureau of Standards.

Materials for the Household

Describes the more common materials used by the household, comprising paint materials, cement, clay products, lime, plasters and stucco, wood, metals, bituminous roofing, inks, and dyes, adhesives, paper, textiles, rubber, leather, cleansers and preservatives, fuels, illuminants and lubricants, and concludes with a chapter on quantity in the purchasing of materials. Each title is treated under the general heads of composition and definition, sources, properties, uses, tests, preservation, hints as to selection and use, and references.

Circular No. 68 of the Bureau of Standards.

Combined Table of Sizes in the Principal Wire Gages

A table combining in one series the sizes in the American (B. & S.), Steel, Birmingham (Stubs'), British Standard, and Metric wire gages, arranges in order of diameters of wires. It gives the diameters of all the gage numbers in these five systems in mils, inches, and millimeters, also the cross-sections in square mils, circular mils, square inches, and square millimeters. The table is specially useful to manufacturers who wish to determine the nearest equivalent in American or British gage sizes of wires specified in millimeters or square millimeters, or vice versa.

Circular No. 67 of the Bureau of Standards.

The Determination of Absolute Viscosity by Short-Tube Viscosimeters, Winslow H. Herschel

The Engler and the Saybolt Universal viscosimeters, which are the instruments usually employed in the oil trade, have such short outlet tubes that the equation for the flow through long capillary tubes is not applicable without correction factors. The literature has been carefully reviewed and further experimental work has been done. The conclusion is reached that water is not a suitable liquid for use in finding the relation between viscosity and time of discharge for short-tube viscosimeters, and that Ubbelohde's equation, and all others based upon it, are seriously in error.

Technologic Paper No. 100 of the Bureau of Standards.

An Investigation of the Axial Aberrations of Lenses

In Scientific Paper No. 311 of the Bureau of Standards, the errors which affect the definition of a lens are discussed, and methods of graphically representing the central errors described. The condition for freedom from coma near the axis is arrived at. The relative importance of the errors in different types of lenses is discussed. Hartman's method is extended, permitting one set of measurements to give all the important central errors—spherical aberration, zonal variation of equivalent focal length, and axial and oblique achromatism. The apparatus and procedure are described, and the accuracy of the adjustments and the measurements discussed. The method is applicable to all systems of relatively short focus and large aperture, such as photographic lenses, projection lenses, and telescope objectives, and also to complete optical systems. The results of the method as applied to a complete telescope are discussed and shown to be independent of the accommodation of the observer. Seventeen sets of curves are given for as many different lenses, and an illustrative discussion of one set of curves, together with a general description of the types of lenses represented by each group of curves.

The Effect of the Size of Grog in Fireclay Bodies

The size of grain has long been known to exert considerable influence upon the properties of mortars, concrete, fireclay

refractories, and other materials. Technologic Paper No. 104 of the Bureau of Standards describes an investigation in which is determined the effect of the size of the calcined portion, or grog, upon the properties of the fireclay bodies within a field of practical sizes. The general plan of procedure consisted of separating grog into a number of sizes, recombining these in arbitrary proportions by calculation from triaxial diagrams, mixing with an equal weight of clay, and molding with water into test pieces for the determination of various properties. Strength in the raw state, as indicated by the modulus of rupture, depended upon a number of factors and did not vary directly with the size of the grog. Proper proportioning of grog sizes gave stronger bodies than single grog sizes. The strength of burned bodies increased directly with decrease of the size of grog, the size being expressed numerically as a surface factor. Bodies containing the larger sizes were more resistant to sudden heating and cooling from 600 deg. cent. and 1000 deg. cent. Volume shrinkage in burning to cone 12 increased approximately with decrease of porosity. No relation was found between strength and porosity in the dry or burned states. Methods are suggested for proper proportioning of grog for glass pots, saggers, and similar bodies.

Wave-Length Measurements in Spectra from 5600 A to 9600 A

Some work in spectroscopic analysis at the Bureau of Standards showed the importance of investigating the red and adjacent infra-red regions of spectra more carefully and extensively. Ordinary photographic plates were stained in a mixture of dicyanin, water, alcohol and ammonia to make them sensitive to the long light waves. These stained plates were used to photograph the arc spectra of twenty of the chemical elements, including the alkali metals, the alkaline earths, and elements commonly found in iron as impurities. The photographs were made in the first-order spectrum with a concave grating of 640 cm. radius, the grating being mounted in parallel light. This spectrograph gives a dispersion of about 10 A per mm. in the first order. With this apparatus exposure times of 30 min. sufficed to record waves longer than 9000 A (A = Angstrom = 0.0000001 mm.) and demonstrated the value of dicyanin as a photographic sensitizer for such spectral investigations. Waves which are 2000 A longer than the longest waves in the visible spectrum were thus detected photographically without difficulty.

Accurate measurements of wave lengths and determinations of the characteristics of the emission lines were obtained from these spectrograms. The second order spectrum of the iron arc was photographed on either side of the first order and the long wave lengths were obtained from the standards in the iron spectrum. In this paper the wave lengths in International Angstroms are given for the arc spectra of the following elements: lithium, sodium, potassium, rubidium, cæsium, copper, calcium, strontium, barium and magnesium.

Frequency differences of doublets in the spectra of sodium, potassium, rubidium, cæsium and copper are shown by these wave-length measurements to be constant in most cases to one part in 100,000 in the number of waves per centimeter.

Comparison of the spectra made it possible to detect many impurities in the elements used for light sources. Still more extensive spectral investigations are required in the region of long wave lengths to identify all lines correctly. (W. F. Meggers, in Scientific Paper No. 309, Bureau of Standards.)

Typical Cases of the Deterioration of Muntz Metal (60-40 Brass) by Selective Corrosion

Brass of the type 60 copper and 40 zinc, which is used commercially in a variety of forms, e.g., wrought bolts, sheathing, condenser tubes, extruded forms, etc., often shows a kind of deterioration by which the metal changes its color to copper-red and becomes very weak and brittle although the shape and size apparently remain unchanged. This change of properties is due to a selective corrosion of the alloy, which has a duplex structure, when exposed to the action of some electrolyte, particularly sea water. This type of corrosion has been recognized by manufacturers and users of brass for some time; the numerous samples illustrating this kind of deterioration which have been submitted to the Bureau of Standards, however, showed the utility of a description of typical cases of such corroded brasses. The study of such types includes bolts, boat sheathing, condenser tubes, and parts which were corroded while under stress.

The examination of the microstructure shows clearly the method of the attack, the zinc-rich constituent being electrolytically "leached out," leaving a skeleton of weak, pulverulent copper in its place so that the piece becomes very weak and brittle. Later the second constituent may be attacked so that the whole specimen is converted into pulverulent "copper," the sample becoming so weak that it can be broken into fragments in the fingers.

Conditions which appear from the examination of corroded samples to accelerate this type of corrosive attack are: The microstructural composition of the alloy, contact with strongly electronegative metals, the effect of certain adhering deposits of basic zinc chloride resulting from the corrosion, the thoroughness of the annealing the sample has previously received, the temperature of the electrolyte, and the stresses to which the specimens are subjected during the corrosive attack. (Technologic Paper No. 103, Bureau of Standards.)

Capital and Labor in England

At the general meeting of shareholders of Messrs. Dorman, Long & Co., held in Middlesbrough, England, on July 31, Mr. A. J. Dorman, dealing with the future relations between Capital and Labor, said that many took a gloomy view of what was likely to happen after the war, but personally he was not one of those. He believed, if they were allowed to manage their own affairs, employer and employed in conference together would arrive at a happy conclusion. To his mind the problem to be solved was to settle the price at which the workmen would give their best labor free from all restrictions. It must be evident to all thinking men that no high wages could be paid except in return for efficiency and increased output. Given that, a settlement would be an easy matter, for the employer did not ask for increased hours and harder work—improved machinery would do the hard work. Under such conditions it is possible to pay higher wages and yet produce at lower cost. British manufacturers could assemble their material at less cost than most nations, and had shipping facilities second to none. They had received little or no encouragement to embark in large commercial undertakings, and their machinery had been allowed to become somewhat antiquated, but a new life was springing up within them, and, if only a fair understanding could be come to between Capital and Labor, he had no doubt that the new industries that had been brought into being would prove to be a source of great prosperity to the country and

enable it to hold its own in the markets of the world. For obvious reasons, there was not likely to be any great alterations in their returns during the continuance of the war, but when peace came it would doubtless bring with it a large demand for shipbuilding and constructional material, for which they would be well prepared.

Sixth Annual Safety Congress

The Sixth Annual Safety Congress of the National Safety Council was held at the Hotel Astor, New York, Sept. 10 to 14. Concurrently with the congress was held an exhibition of safety and sanitation devices at the Grand Central Palace. This exhibition is claimed to be the largest and most complete ever held. The work of the congress was divided into the following groups: Public Safety Division, Public Administrative or Governmental Division, Health Service and Industrial Relations Division, Transportation and Public Service Division, and the Industrial Division. The Transportation Division was subdivided into four sub-sections, viz.: Electric and Street Railways, Marine and Navigation, Public Utilities, and Steam Railroads. The Industrial Division was formed by the following sub-sections: Chemical and Rubber; Logging, Lumbering and Woodworking; Metals and Metallurgy, including Foundries, Iron and Steel Works; Mining and Quarrying; Automobile Manufacturing; Car Builders; Paper and Pulp; and the Textile Trades.

American Chemical Society

The meeting of the American Chemical Society, held in Cambridge and Boston, September 10-13, was, to a large extent, of the nature of a review of the great work done by American chemists since the beginning of the war and of the degree of preparedness for the days of peace, however distant. The meeting was well attended and attracted a considerable amount of attention throughout the country.

Arthur L. Day, Director of the Geophysical Laboratory in Washington, gave an address on the Establishment of Optical Glass Manufacture in America. Up to the time of the war this country was dependent on Germany and France for its optical glass. The details of manufacture could not be obtained by the American Government from the governments of England or France, as the processes were secret and not known to these governments. The problem which was there and then put up to the Geophysical Laboratory was to make a satisfactory glass out of American raw materials and to do it quickly. After careful figuring by the Army and Navy officials it was decided that six was the minimum of different kinds of necessary glasses. In this work the Geophysical Laboratory was assisted by the Bausch & Lomb Co.

The difficulties were many, both in the way of lack of information and securing proper raw materials, but they have all been gradually solved, and it is expected that with the knowledge now available a glass equal to any used in Europe can be made in this country.

William H. Nichols, chairman of the Committee on Chemicals of the Council of National Defense, presented an extensive address on the Work of the Committee on Chemicals. An organization with the view to securing proper chemicals has been taken up by the Washington authorities since the declaration of war. The present organization is, in the opinion of the speaker, temporary. In all, the Chemical Committee with its sub-committees includes some 37 men, practically all of whom are leading men in their respective branches of industry. In general, the manufacturers have responded most cordially to the demands made upon them by the committee, and there are many instances of sacrifices being made for which recognition is not expected and will, probably, not be received. There are exceptions, but every effort is being made to produce satisfactory results without resorting to higher authority.

The one great need of any colossal organization is the complete coördination of all its parts. No one can claim that the organization in Washington has yet reached this stage or even approximated it. Many things are done several times over and many others needed are not done at all.

Dr. M. T. Bogert presented an address on the Work of the Chemistry Committee of the National Research Council, reviewing its activity in the mobilization of research chemists in war work. The most important field of their work is in the production of poisonous gases, gas masks, gas shells, the absorption of hydrogen gas in the submarine battery rooms, and the related U-boat problems.

Among the divisional meetings, one of the most interesting was the conference held by the Industrial Division on the Industrial Chemist in War Time. Dr. L. H. Baekeland, member of the Naval Consulting Board, gave a talk on the Work of the Board. On the whole, there was little encouragement in what he said. The overwhelming majority of the suggested ideas are not worth much, and it has been necessary to issue a pamphlet telling the people what not to do. He said *new* explosives are not what is wanted, but a good supply of those we already know about.

In connection with the meeting a national exposition of chemical industries was held during the week of September 24, an account of which will be given in a later issue of The Journal.

An interesting report on the last meeting of the American Chemical Society will be found in the September 15 issue of *Metallurgical and Chemical Engineering*.

American Association of Port Authorities

Better coördination of terminal facilities back of the docks in American ports bears a close relation not only to reducing the cost of manufacture and the expense of living, but to the economic struggle that is coming after the war. In fact, the elimination of duplicated work and its consequent delays may mean much toward bringing peace in the war now being waged. This preparation for the present fight and the war after the war was emphatically advocated at the convention of American Association of Port Authorities in Cleveland, September 11 to 13.

The enthusiastic reception of this idea showed that the speakers were not alone in placing this interpretation and this emphasis on the resolution calling for increased efficiency of railroad freight terminals connected with ports. The resolution was carried over from last year's convention at Montreal.

The convention was opened Tuesday morning with an address of welcome by E. S. Griffiths, of the Cleveland River and Harbor Commission. This speech was responded to by the president of the association, W. G. Ross, of Montreal. The delegates were entertained at a luncheon reception by the Chamber of Commerce. Officials of the chamber, of the city and of the association made brief talks, and Calvin Tompkins, of New York, former commissioner of docks in that city, was introduced as the principal speaker.

Mr. Tompkins spoke of the way in which the world's shipping is now being administered as a great unit, with an efficiency never before attained. This work shows what can be

done and what probably will be done, at least in a measure, after the war is over.

Papers were read during the day on the following subjects: Establishment of Exact Lines for Port Planning, by Charles W. Staniford, chief engineer of department of docks and ferries, New York City; Administration of New York Canals, by Maurice W. Williams, engineer in charge of mechanical equipment of barge canal terminals; Legal Status of Submerged Land and Littoral Ownership, by Judge Robert M. Morgan, common pleas court, Cleveland. Colonel Lansing H. Beach, United States Engineers, described canal operations in various parts of the country.

How water-borne traffic on the Great Lakes has grown in about half a century from a few small cargoes to one of the greatest tonnages in the world, was interestingly told by Harvey D. Goulder, general counsel of the Lake Carriers' Association. In 1679 the *Griffin,* of about 45 tons, was built just above Niagara Falls. She made one trip and was never heard from again. In the following century a few small vessels appeared. In the forties of the past century a great statesman, in speaking against a land grant for a canal to connect Lake Superior with the lower waters, said one might as well propose to project commerce up into the moon as into the upper lake region. A few years later the state of Michigan made the improvement and the freight movement through the Soo that year was 14,503 tons. In 1916 it was 92 million tons.

The general opening of navigation, Mr. Goulder said, might be fixed as 1855, the date of the opening of the canal. Until after the Civil War the government had spent some \$3,000,000 on lake navigation improvements. Since then it has spent more than \$100,000,000. The great growth of lake freight was accomplished through a gradual growth in size of ships, canals and terminals.

This growth has resulted in cheaper manufactured products not only along the lakes, but in every part of the country, for the cost of carrying grain and ore on the lakes is only about one-tenth the average cost on the railroads.

In the evening an illustrated lecture on the handling of bulk freight on the lakes was given by J. D. Carey, of the Cleveland River and Harbor Commission. He explained with motion pictures how remarkable speed in loading and unloading ships is accomplished through big terminal equipment. By means of grab buckets that pick up in one stroke 15 to 20 tons of ore, a ship of 10,000 tons capacity can be unloaded in 3 hr. 15 min. The same ship can be loaded with ore in 25 min.

The Wednesday session was devoted to the discussion of the resolution adopted at the Montreal convention a year ago, calling on the Interstate Commerce Commission to investigate terminal and port conditions, railroad charges, free wharfage and kindred subjects, and bringing out the need for increased terminal efficiency through pooling and joint use of terminals. This matter had already been taken up with the commission since the previous convention, and is to be considered still further. The investigation probably will be made.

The discussion was opened with a general presentation of the problem of port terminal efficiency in its relation to the economic situation in the Americas and to the preparation for trade expansion when peace comes, by Edward F. McSweeney, of Boston, who first introduced the resolution. Millions of dollars have been spent on docks, he said, but much of it was wasted because there was little vision in planning. Facilities back of the docks were in isolated groups, controlled by separate railroads. Duplication of work and delay and congestion resulted.

In the war after the war—the struggle for foreign trade—the United States must put forth a united effort to win the share of commerce it needs and can supply. The value of this effort will depend largely upon our port arrangements.

The situation in regard to terminal charges and delays was taken up more in detail by Robert Bridges, of Seattle, in a description of that port, where a strong effort is being made to remedy faults. He explained how at several piers it takes 24 hours and costs \$6 to transfer a car from one pier to the next, while with one belt line for the entire port, the same operation could be done in 30 min. for \$2.

Mr. Bridges advocated not only the public ownership or direction of a belt line along the docks and a complete terminal yard, but centralized control of all railroads and the establishment of free ports. Any reduction in the time of handling freight would result in cheaper costs and quicker deliveries, and thus would attract many more factories to the port cities, the natural meeting place of raw materials, Mr. Bridges said.

W. G. Ross, Montreal, was reelected president; William J. Barney, of New York, secretary, and Harry C. Gahn, Cleveland, treasurer.

The next convention will be held in Boston next September.

Wm. J. Nolle.

New England Water Works Association

The Thirty-sixth Annual Convention of the New England Water Works Association was held in Hartford, Conn., September 11 to 15. The choice of Hartford as a place of meeting afforded a splendid opportunity for the study of the extensive new Water Works of that city now nearing completion. An interesting program, including addresses by specialists on problems of water-works design, construction, and management, was carried out.

Hon. Frank A. Hagarty, Mayor of Hartford, extended the greetings of the city, and commented on the extensive provisions for water supply for Hartford. Hon. Charles H. Clark emphasized the economy in water consumptions due to metering of water and made a plea for the treatment of municipal waste before its introduction into public water courses. Hon. Charles E. Goss advocated a dual water supply for cities—one serving domestic and the other industrial needs.

In his presidential address Mr. Caleb M. Saville, Chief Engineer of the Water Department of Hartford, outlined the qualities demanded in water-works executives and emphasized the necessity of broader training in the financial and economic aspect as well as design and construction of water works.

George A. Johnson discussed exhaustively the problems of rapid sand filtration and pointed to the ascendency of the mechanical or rapid sand filter. He called attention to the fact that 74 per cent of the filtered water in this country is supplied by rapid filters. He also pointed out the great diminution in typhoid during the last three decades and ascribed it in large part to water purification.

In the discussion which followed this paper the topics of prevention of tastes in waters treated with sulphate of alumina and the conservation of wash water were discussed by R. S. Hastings, W. C. Hawley, and others.

Robert S. Weston reviewed the development of mechanical filter bottoms and strainer systems and discussed in detail the advantages of the Wheeler strainer, particularly the elimination of metal parts, securing a uniform distribution of wash water and a minimum thickness of gravel. The care and operation of rapid sand filters formed the subject

of a paper by John W. Gatenby, while a paper by F. L. Cady described the slow sand filters in use in Providence, R. I. Delos F. Wilcox described the problems encountered by the city of New York in dealing with the five privately owned companies within its city limits.

Bertram Brewer explained the means employed for reducing water rates in Waltham, Mass.

Papers on water works shop construction were delivered by A. L. Martin and H. W. Hosford. H. R. Turner described the operating problems of a small Water Works Department.

A paper on the control of Microscopic Organisms in Water Supply by William Hame was warmly discussed.

After a general exposition by President Saville of the water system of the city of Hartford, a detailed description of the system was given by the members of the Engineering Staff. Particularly interesting were the descriptions of the construction of the Masonry Dam on Nepaug River, the design of Spillway at Richard's Corner Dam, Grouting of Dam Foundations, and the development and designing by H. W. Griswold, R. E. Wise, J. E. Garrett, W. E. Johnson, Frank Brainard, H. W. Horne, and J. H. Shaughnessy.

In dealing with the subject of Pollution of Streams in Connecticut, J. L. Jackson deplored the failure to restrict the discharge of wastes into streams which might otherwise be excellently adapted for drinking purposes.

S. E. Killam outlined the means by which Boston was enabled to postpone by many years its proposed extension to its water system by reducing its per-capita consumption from 109 to 80 gal. per day, through the installation of service meters.

The papers will be published in full in the Quarterly Journal of the New England Water Works Association.

Gravitation

In the daily papers of September 19 it was stated that a new theory as to gravitation will be announced soon before the St. Louis Academy of Science by Prof. Francis E. Nipher, retired head of the department of physics of Washington University. In a written statement Professor Nipher said:

"It will be shown that gravitational attraction between masses of matter not only has been diminished into zero, but has been converted into a repulsion which is more than twice as great as normal attraction."

Professor Nipher is reported to have made his experiments with bodies suspended horizontally toward each other. By introducing electricity into the atmosphere he converted normal attraction into repulsion.

"If electricity can alter the gravitational attraction of the bodies used in my experiments," he said, "the same force can alter the earth's attraction. If the negative electricity could be drawn from the earth's surface, gravitational attraction suddenly would cease and the coherence of the earth's surface would be disastrously affected."

This Month's Abstracts

A. Leon, in the *Journal of the Society of German Engineers*, discusses the subject of fatigue of machine parts, more particularly the distribution of stresses in machine parts at points where the section of the members concerned becomes wider or narrower.

The variation of temperature in dams of various thicknesses during the period of setting in concrete forms the subject of an investigation by R. A. Monroe. He found that first this variation is different in thin arches from that occurring in thick arches, and second, the temperature of a concrete wall of light thickness (14 in.) follows that of the air with remarkable closeness.

The Bureau of Standards has investigated, with characteristic thoroughness, some unusual structures of wrought iron apparently due to the presence of a high content of phosphorus. One of the remarkable characteristics of the structure investigated is its persistence upon heating, which suggests a possible bearing on the failure of material in which it occurs.

Description of apparatus and processes for testing rails by the quick-bend method as carried out by the Pennsylvania Railroad will be found in the section Engineering Materials. It is stated that this method displaced the drop test formerly used, because the now nearly universal use of open-hearth steel rails has made necessary a method which, in addition to detecting possible brittleness, would also determine the ranges of elasticity and ductility of the steel.

Data on the spark length in various gases and vapors are presented by Robert Wright in a paper in the *Journal of the Chemical Society*. This appears to be the first investigation of this kind of electric ignition carried out under conditions enabling comparable results to be obtained.

Another feature of the design of internal-combustion engines is covered in an interesting manner in an article on bulb experiments in hot-bulb engines published in *The Engineer*. The article discusses the design of the hot bulb and reports experiments with various types of this important auxiliary.

The McEwen high-compression oil engine described in the section Internal Combustion Engineering operates on the Diesel principle. Its interest lies primarily in the fuel valve and method of governing fuel injection, and in the design of a comparatively simple air compressor.

The paper by William Alexander before the Institution of Mechanical Engineers describing the energy diagram for gas mixtures in British units and some of its uses is of considerable interest, and would have been still more valuable had the actual charts been reproduced. As a matter of fact, however, the only chart reproduced is the combined chart of entropy temperature and entropy total heat as found in the abstract in this issue. The writer derives expressions for the various relations affecting the energy derivation in the gas mixture, and in addition gives, by way of illustration of the use of the diagram, some data on the comparison of thermal diagrams for large and small Diesel engines. This part of the paper is of considerable interest in itself, but could not be abstracted here because of lack of space.

Alan E. I. Chorlton's extensive paper on the construction of turbine pumps could be only briefly abstracted. It is particularly interesting because of the careful classification of the various types of turbine pumps under the headings of the various component parts of a pump. It is interesting to note that the writer does not believe that the so-called balanced-type of single-eye wheel of multicellular pumps is actually balanced, and claims that the advantage of being in balance is a purely paper one. Disturbing factors are set up for various influences, and in practice it is necessary to provide additional balancing means of one type or another.

A 120-ton coal car for the Virginian Railway, described in the section Railroad Engineering, is of interest not only because of its huge size, but also because of some features of construction which made the use of such a large unit possible and safe.

REVIEW OF ENGINEERING PERIODICALS

Engineering Materials

Fatigue of Machine Parts. A. Leon

(*Zeits. Vereines Deutsch. Ing.*, vol. 61, pp. 192-196, March 3, and pp. 214-218, March 10, 1917.)

The common assumption that pure tension or compression is distributed uniformly over the whole section, and that the variation of stress is linear in the case of bending, is not justified where the section of the members concerned becomes wider or narrower. There the nature and distribution of stress are complicated, and this is an important factor in machine parts, especially in moving parts of complex form which are subjected to alternating stresses. A notched test bar loaded gradually to the breaking point behaves differently according as the metal is brittle or ductile. In brittle materials the distribution of stress remains uneven until fracture occurs (at lower load than corresponds to the strength of a smooth bar of the material). A ductile material, on the other hand, gives greater strength when notched than when in the plain bar; once the yield point is passed, the extension increases rapidly and the stresses are equalized to an increasing extent. Cross stresses are also set up which reduce the risk of breaking. The author gives curves and formulæ relating to longitudinal and cross stresses, and changes in the corresponding dimensions of a notched rubber rod. A notched rod of ductile material does not contract over the whole breaking section, but only in the immediate neighborhood of the slot bottom. The section after fracture is relatively less contracted than in a smooth rod, hence the greater breaking load. Under repeated, and particularly under alternating, stress, ductile material behaves like brittle material; where the limit of elasticity is exceeded, the material is given a "set" first in one direction, then in the other. As a result it becomes fatigued, small cracks appearing which gradually deepen and extend until failure occurs. Wöhler's tests show the danger of sharp changes in section. St. Venant showed that notching causes local increases in pressure of at least 100 per cent. Failure under alternating load occurs at a point where the stress distribution is affected unfavorably by a hard or soft inclusion, or by complete interruption of the elastic cohesion. Heating of specimens during alternating-stress tests is an indication that the elastic limit is being exceeded, so that inelastic changes in form are occurring and failure will soon take place. In order to tell whether the elastic limit will be exceeded in a constructional part, it is necessary to know the actual distribution of stress. Alternating tensile and compressive stresses up to about 85 per cent of the elastic limit, or 45 per cent of the ultimate tensile strength, do not cause failure of mild steel until the number of load reversals exceeds 1,000,000; the rapidity of reversal of the load also affects the life test. The author mentions Beilby's hypothesis of an amorphous modification of the metal as a possible explanation of fatigue phenomena. Ludwik suggests a loosening of the metallic structure by repeated stressing. Under alternating torsion the change in form is localized more and more until only a single layer of material is "working"; this intensifies local variations in stress and increases the risk of fracture.

Bauschinger's tests on various grades of iron show the ratio of steady tensile strength to initial and to alternating strength to be 1 : 0.56 : 0.49. In other words, the initial strength is only about 14 per cent greater than the alternating strength. The author defines "notch ratio" as the ratio of greatest to smallest width of rod; and the "notch figure" as the ratio of greatest mean stress (referred to the useful section). The reciprocal of the notch figure is the "utilization figure." A circular hole in a plate causes 200 per cent increase in stress at two points on the edge of the hole, i.e., the notch figure is 3, compared with 8/3 for semicircular edge notches. The author cites values for these factors as determined by various investigators, and gives curves for the stress distribution in a perforated rubber rod subjected to tension. Comparison is made between mild steel subjected to small distortion and rubber subjected to great extension. The author gives tables of data from his own tests on rubber rods, and local and average extension. The large deformation in rubber specimens equalizes stress distribution to some extent. For instance, with a notch ratio of 5 the notch figure decreased from 3.15 to 1.98, corresponding to mean extensions of 11 and 37 per cent and maximum local extensions of 36 and 75 per cent. Curves in the original show the distribution of primary and secondary stresses in a perforated stone block subject to compression, and in a rubber specimen with rectangular holes. The secondary (cross) stresses are important. These tests have a bearing on the influence of rivet holes on the strength of parts. Fillets may affect stress distribution unfavorably, and examples in the original show the proportion of various sections which is rendered idle by ribs or fillets. The final section of the paper includes a number of useful notes concerning the effect of various changes in sections, slotting, polished or ground surfaces, and various means of observing these effects and compensating for them. The paper relates rather to the general phenomena and problems of stress distribution than to specific machine parts. (*Science Abstracts,* Section B—Electrical Engineering, vol. 20, part 7, July 30, 1917, no. 235, pp. 225-226, *t*)

How Temperature Varied in Two Dams While Cement Was Setting, R. A. Monroe

In planning the recent 40-ft. height increase of the Lake Spaulding dam of the Pacific Gas and Electric Company in northern California, it was decided to determine how temperatures varied within the concrete. Accordingly, as the work was under way, thermometers in the shape of thermocouples were put in at predetermined locations, so that records could be kept. The same tests were applied to a dam of the multiple-arch type in order that the effect in thin arches might be compared with that observed in a structure of large section.

In the large dam the thermometers were located both at the center and near the surface, while in the thin arches only a central location was used.

The data are presented in the form of tables. From them it is seen that the temperature of the freshly placed concrete was 47 to 48 deg., and in eleven days it rose noticeably across the entire section. At the upstream face the gain was 27 deg.; at the downstream face, 22.5 deg., and at the center 43 deg., or, roughly, twice as much as at the faces. (These data refer to the Spaulding dam.) In two months the temperature of the concrete 1 ft. from the faces of the dam had returned to normal atmospheric temperature, while that of the center of the section was still 20 deg. above normal atmospheric temperature, and falling at the rate of 3 deg. per week. A reading taken over six months from the time of pouring showed the concrete at the center to be 4 deg. above that at the faces, but at practically mean atmospheric temperature for the preceding month.

The results in the case of the thin arch were different. In the design of the arch it was assumed that due to the chemical action of the cement the setting temperature of the concrete in the arch wings would be 10 deg. above the average daily temperatures. Actually, a rise of 17 deg. above the mean was discovered. The results as presented in a table also show that the highest temperature was attained in about 18 hours after pouring, or shortly after the concrete had taken its permanent set, but that this temperature was maintained for only a few hours.

Another interesting thing which was noted was how closely the temperature of a concrete wall of this thickness (14 in.) follows that of the air, and these results indicate clearly that in a structure of this type provision must be made for a temperature variation of approximately the same magnitude as shown by atmospheric records. (*Engineering News-Record*, vol. 79, no. 6, August 9, 1917, pp. 253-254, 3 figs., *e*)

Some Unusual Structures of Wrought Iron, Henry S. Rawdon

Data of an investigation carried out at the U. S. Bureau of Standards in which sections of wrought iron which have failed have been investigated chemically and microscopically, and as a result attention is called to the detection of certain impurities and their possible influence on the physical properties of the metal.

As a rule, in wrought iron no definite orientation of crystals, or grains, is apparent, but the presence of slag in the ferrite matrix is usually revealed by the appearance of streaks.

In some cases, however, the ferrite crystals presented a mottled appearance, particularly after prolonged etching with an acid reagent. This etch pattern was not found over the entire surface of the specimen, but was restricted to certain streaks throughout the metal. Particularly was it found associated with crystals unusually large in size.

By using a copper-chloride etching reagent these patterns may be developed in a striking manner. Crystals of ordinary wrought iron will not exhibit such etch patterns even after very prolonged heating.

The examination of the metal close up to the fracture which occurred during its service shows that the break took place through the crystals and parallel to the markings constituting the mottled etch pattern at that point.

The writer comes to the conclusion that the non-homogeneity of the individual crystals as indicated by the mottled etch pattern is to be attributed to some impurity dissolved in the iron, but not uniformly diffused throughout the crystal.

An examination of several pieces revealed that the unusual microstructure described above is found only in material relatively high in phosphorus, but analysis for phosphorus shows that though such unusual features of structure are invariably associated with irons which are rather high in phosphorus, one cannot predict with certainty their presence from a knowledge of the average phosphorus content alone.

One of the remarkable characteristics of this inter-crystalline structure is its persistence upon heating. After heating a specimen of a wrought iron eyebar for three hours at approximately 600 deg. cent., no appreciable change in structure was found. A second sample heated for about one and a half hours at approximately 725 deg. cent. and furnace-cooled still shows faint traces of the former condition.

The eutectic disappeared, but the non-homogeneity of structure is still apparent from the dendritic pattern. This illustrates the remarkably slow rate of diffusion of phosphorus in the ferrite matrix, and explains why the mottled structure is not wiped out during the processes of heating, rolling and forging constituting the manufacture of wrought iron.

These unusual features of microstructure suggest a possible bearing on the failure of material in which they occur. The brittle character of ferrite containing considerable phosphorus is well known. Crystals which show the heterogeneity caused by high- and low-phosphorus bands in juxtaposition are more apt fatigued by repeated stresses than crystals more uniform in their structure. This applies particularly to bands transverse to the direction of the stresses acting.

Examination of a series of wrought irons showed, however, that such features are not to be regarded as common. Many poor grades of iron may be unsuitable for other reasons. (*The Iron Age*, vol. 100, no. 10, September 6, 1917, pp. 538-540, 7 figs., *t*)

Testing Rails by the Quick-Bend Method

Description of an apparatus recently built by the Pennsylvania Railroad to replace the drop test. The Pennsylvania Railroad introduced the present drop test into its specifications for carbon-steel rails in 1900, at which time the rails were produced by the bessemer process only and brittleness was to be guarded against. Since 1908, however, open-hearth-steel rails have come into general use and at the present time practically all orders for rails on the Pennsylvania Railroad are of this nature.

On the open-hearth rail, however, the drop test gives very little information on the relative merits of rails from different manufacturers. It was therefore thought that a transverse rapid-bending test as an alternative to the standard drop test might give more conclusive information relative to such

physical properties as elasticity, ductility and hardness of the material.

The quick-bend test machine was placed in service about May, 1917. It consists of a hydraulic press and intensifier. The press is of the four-column inverted type, having a clear distance of 3 ft. 4 in. by 12 in. between columns. The main ram, 16 in. in diameter with a 12-in. stroke, is cast solid with the moving platen, which is guided on the four columns. The twin pull-back rams, 6 in. in diameter, are symmetrically located at the sides of the main ram.

The intensifier (Fig. 1) is of the single-pressure type with a total weight of approximately 11,000 lb. The ram which extends from the high-pressure cylinder to the base-pressure cylinder is integral with the base-pressure piston and has a total stroke of 36 in. The diameters of the ram and the base-pressure piston are 9 in. and 26 in. respectively, which gives a step-up ratio of about 8.35 to 1.

The operation of the machine is controlled by a bronze three-way valve having a balanced exhaust. By admitting 450 lb. per sq. in. line pressure to the base cylinder of the intensifier, the pressure in the high-pressure cylinder thereon and consequently in the ram cylinder of the press is raised to approximately 3760 lb. per sq. in., developing a total capacity in the press of about 756,000 lb. The 36-in. stroke of the intensifier ram actuates the entire 12-in. travel of the main ram by intensified pressure alone, thus assuring a smooth, continuous curve of the indicator card.

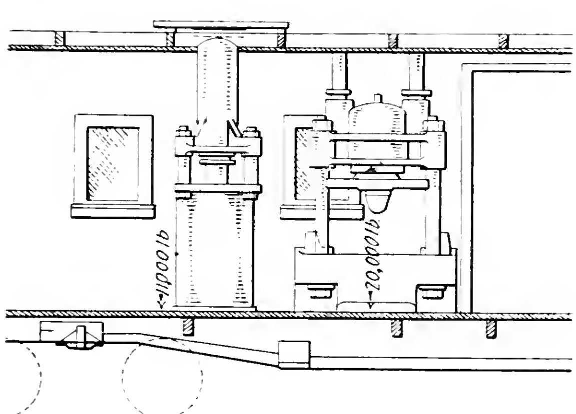

Fig. 1 Pennsylvania Railroad Machine for Testing Rails by Rapid Bending

The hydraulic indicator is used to register the pressure required for a relative deflection of the specimen, the indicator being in direct communication with the main ram chamber.

The rail test specimen is placed on the supports of the press and pressure is applied through the loading head of the ram at the center of the rail until rupture of the specimen occurs. During this action, which requires approximately seven seconds, the indicator card showing increments of deflection and corresponding pressure is taken. In this card the curve is drawn of which the abscissae indicate deflections and the ordinates the loads in thousands of pounds. The elements taken from the card are the deflection and load at the elastic limit and the ultimate strength, while the work required to fracture the specimen may also be obtained.

It has been demonstrated from comparative drop and quick-bend tests that rails which have to meet the drop-test requirements showed undesirable physical properties when subjected to the quick-bend test. The quick-bend test is of particular advantage in the determination of the ranges of elasticity and ductility of the steel. (*Railway Age Gazette*, vol. 63, no. 10, Sept. 7, 1917, pp. 413-415, 3 figs., *d*)

Internal Combustion Engineering

Spark Length in Various Gases and Vapors, Robert Wright

The different factors affecting the phenomenon of electric discharge, in so far as the length and nature of spark, voltage, gas pressure and temperature relations in the spark are affected, have formed the subject of a large number of investigations (compare The Journal for January 1917, p. 86), but the wider chemical relations have been investigated a good deal less.

Natterer, in 1889, published an examination of the spark discharge through a number of gases and vapors at atmospheric pressure. His method of investigation appears to have been, however, quite crude, and the data cannot be relied upon.

As regards the effect of temperature of the gas on the spark, Harris, in 1834, and Cardani, in 1888, both found that the temperature has no effect on the spark, provided that the number of molecules per cubic centimeter of the given gas remains constant. That is to say, if the spark gap be enclosed in a gas-tight vessel, then the voltage required to produce a spark will be quite independent of the temperature: but if the vessel be left open so that the gas can expand at atmospheric pressure, then increase of temperature causes increases of spark length for a given voltage. The effect is exactly the same as if the gas concentration had been reduced by lowering the pressure in the ordinary way, the temperature remaining constant. In the present investigation a 20-mm. gap at 100 deg. cent. was found to correspond with 15 mm. at 18 deg. cent. and 20 mm. at 183 deg. cent. with 5 mm. at 18 deg. cent.

TABLE 1 RELATIVE SPARK LENGTHS IN MILLIMETERS

Substance	Air gap 30 mm.	Air gap 20 mm.	Temperature, deg. cent.
Methane	29	20	100
Methyl chloride	24	16	100
Methylene chloride	9	6	100
Chloroform	5	3.5	100
Carbon tetrachloride	1.5	1	100
Methyl bromide	12	9	100
Methyl iodide	8.5	5.5	100
Ethane	24	18	100
Ethyl chloride	21	16	100
Ethyl bromide	9	6.5	100
Ethyl iodide	6.5	4.5	100
Ethylene	35	27	100
Acetylene	32	26	100
Water	40	36	138
Methyl alcohol	30	26	138
Ethyl alcohol	23	19	138
*iso*Propyl alcohol	18	15	138
*iso*Butyl alcohol	16	13	138
Ethyl formate	14		138
Ethyl acetate	11	..	138
Ethyl propionate	8	..	138
Carbon dioxide	16	11	100
Sulphur dioxide	10	6	100
Carbon disulphide	8	5	100
Hydrogen sulphide	17	12	100

In the present investigation the vapors of a number of simple organic substances were sparked under conditions enabling comparable results to be obtained. Among other things, a fairly constant voltage was arranged for by having an air gap of similar form and definite length coupled in parallel with the vapor gap, both gaps being at the same temperature. In each measurement the length of the vapor gap was adjusted so that on carefully raising the potential it sparked equally with the standard air gap. Thus the measurements may be taken as representing the insulating powers of the various substances relative to that of air at the same temperature and pressure.

It is interesting to note that for various reasons, fully explained in the original article, it was found advisable to abandon measurements made by comparing vapors at their boiling points with air at the same temperature. It was also found that, whether the air gap is heated or not, it is of the first importance that all vapors with which comparative measurements are being made should be at the same temperature.

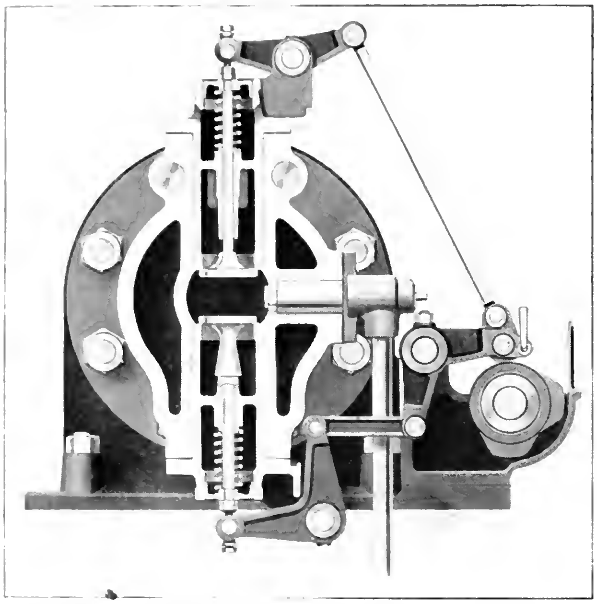

Fig. 2 Suction Through Valve Chamber of McEwen High-Compression Oil Engine

The apparatus used is described in detail. The results given in Table 1 have been obtained, but no claim for great accuracy is put forward, even though each figure is the mean of several readings which never varied among each other by less than 10 per cent. Still, for any series of comparable substances, increase of molecular weight is accompanied by increase of insulating power, but the method is not sufficiently accurate to determine whether the property is a purely additive one or not. In fact, it appears that the curves connecting the potential and length of spark for different gases may intersect one another, and this result was actually obtained in the case of carbon dioxide and air.

An attempt to measure the spark length for several of the substances in the liquid state proved to be a failure. However, we can scarcely expect that any simple agreement could exist in the case of liquids, for, first, the extra factor of surface tension has been introduced, and, second, the relationship between number of molecules and volume which holds for gases no longer exists here. (*Journal of the Chemical Society*, vols. 111 & 112, no. 657, July 1917, pp. 643-649, 2 figs., *e*)

McEwen High-Compression Oil Engine

The McEwen engine is of the four-cycle high-compression type which operates on the Diesel principle and is adapted to burn any kind of heavy crude oil or residue.

As shown in Fig. 2, the inlet and exhaust valves are vertical and the fuel-injection nozzle in the center of the head. The operating camshaft driven by a gear on the crankshaft is supported independently of the cylinder, so that the cam thrust is taken up directly by the engine foundation, thus relieving the frame of stresses from this source. To take off the cylinder head it is necessary only to disconnect the exhaust pipe and fuel line, knock out the pins on the valve levers and remove the nuts from the head bolts.

The piston is in one piece of the truck type and is air-

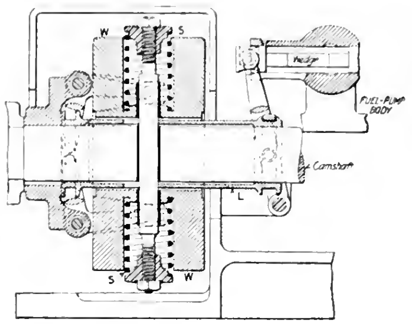

Fig. 3 Governor and Parts of Fuel Valve of the McEwen Engine

cooled. The length of the rod, and thus the compression, may be altered by inserting distance pieces between the rod and the boxes.

In the fuel pump no stuffing box is used, the plunger being

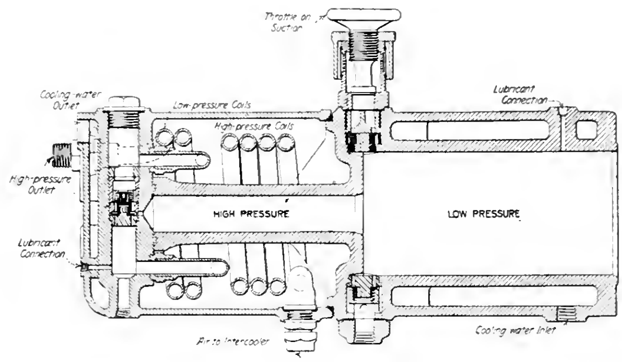

Fig. 4 Air Compressor of the McEwen Engine

case-hardened and ground. This plunger is operated against a spring and the return stroke is controlled by a wedge which is actuated by the governor, Fig. 3.

This governor consists merely of the weights W held by spring S and connected by bell cranks to the sliding sleeve L, which in turn connects with the wedge. As the speed increases the weights fly out, causing the bell cranks to slide the sleeve to the right and shove the wedge in farther. This shortens the return stroke of the pump, decreases the suction, and feeds less fuel to the spray nozzle.

A two-stage air compressor self-contained in a single barrel is driven by a small crank on the end of the main shaft. As shown in Fig. 4, the first- and second-stage cooling coils are

integral with the combined high-pressure head and water jacket.

The high-pressure air goes to the fuel spray line which is provided with a seamless steel-tube receiver to prevent any fluctuation in pressure. The pressure and output of the compressor is controlled by a throttle on the suction line of the low-pressure end, and when it is desired to charge the starting tank this throttle is opened and the charging air taken off between the high- and low-pressure stages. The air starting valve is in the side of the cylinder head (see Fig. 2).

The cooling water first comes to the compressor, then is passed to the engine cylinder jacket and finally to the cylinder head. Neither the piston nor the exhaust valve is cooled. Based on 50 deg. fahr. entering temperature and 140 deg. fahr. exit temperature, the builders estimated a water consumption of approximately 3.5 gal. per hp.-hr. In rating the engine a conservative mean-effective pressure of about 68 lb. is figured on, allowing for 10 per cent overload for two hours. (It is stated that the engine actually carried for a short period as much as 25 per cent overload.) (*Power*, vol. 46, no. 10, September 4, 1917, pp. 321-323, 7 figs. *d.*)

Some Bulb Experiments in Hot-Bulb Engines

With the hot-bulb engine it is always a matter of considerable difficulty to get absolutely complete combustion of the fuel oil. In all engines that inject the oil direct into the cylinder with a pump the oil enters as a jet, and as it is in a more or less solid form, it is extremely difficult to obtain smokeless combustion, owing principally to imperfect pulverization causing the particles of oil to be too large to burn completely during the short period the oil is in the cylinder. Further, if the nozzle is of an imperfect form there is also a danger of the oil carrying over too far and depositing on the sides of the combustion chamber.

With air injection it is possible to obtain greater turbulence and mixing in the combustion space, with the result that cleaner combustion is obtained.

The author [not named] carried out a series of experiments to determine the best form of bulb. Both air- and solid-injection systems were tried, and, while no absolutely uniform conclusions can be drawn from the experiments, forms of bulbs were determined that for certain classes of heavy oils are claimed to be smokeless.

It was also found that when new sizes of engines were built embodying the best results, some of them did not come up to expectations, while others exceeded the best that had been obtained, thus illustrating once more the statement that each size of each type of oil engine is a law unto itself.

Fig. 5 (of which only the top part is reproduced) shows a section of an ordinary crankcase compression two-cycle hot-bulb motor. The cylinder cover was water-cooled and the injection valve was placed horizontally in it, so that it was necessary to deflect the jet up into the bulb by drilling the nozzle hole at an angle.

For the air-injection type the form of bulb shown in Fig. 5 was found to be the best and most durable, and practically all classes of fuel could be smokelessly consumed. In addition, it was possible when the correct compression was found (about 140 to 150 lb. per sq. in.) to run at full speed without the aid of a water-drip to regulate the temperature of the bulb.

The water-cooled cylinder cover possesses an advantage that is very convenient should the supply of water give out. As the air is compressed into the bulb through a water-cooled throat, the temperature of the bulb can be kept within all practical limits, by regulating the temperature of the water around the throat.

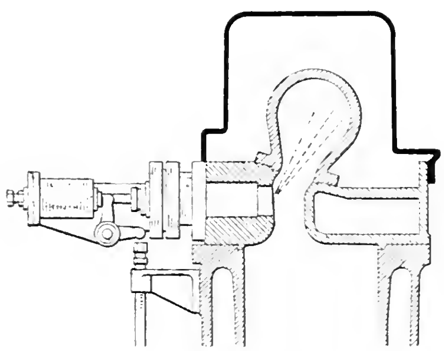

Fig. 5

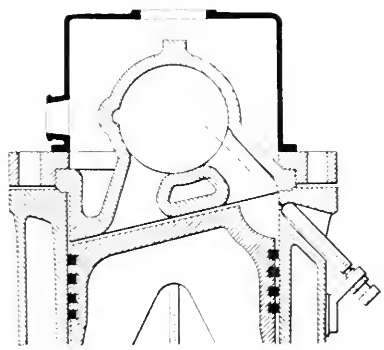

Fig. 6

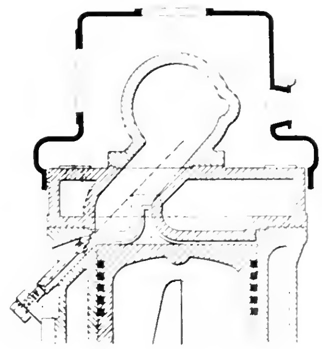

Fig. 7

Figs. 5 to 7 Various Types of Hot-Bulbs Tried Out with Solid and Air Injections

In all designs of hot-bulb motors with water-cooled cylinder covers the bulbs are very small as compared to those (see Fig. 6) in which the bulb and cover are made as one uncooled casting. Bulbs are therefore very cheap to replace, and as the air in the cylinder is kept cooler by the cover, it is denser, and consequently a higher mean pressure can be supported and a more powerful engine obtained, which was proved by the experiments.

As regards the comparative merits of solid and air systems of injection, the writer states that it is safe to estimate an increase of 15 per cent in the power of air-injection over solid-injection engines, which compensates for the complications added by the compressor. On the other hand, it requires a more intelligent driver to operate the engine, and this type should only be installed when good attention can be given. It is also better adapted for the larger sizes of engines and it is the writer's opinion that it should not be fitted to engines giving less than 40 to 50 b.hp. per cylinder.

Practically speaking, any of the six forms of bulb illustrated in the article can be used for air injection with smokeless combustion, and further, it was found that the testing expenses and time required for tuning up was less for a new size of engine of this type than for a new size of the solid-injection type.

For the latter the form of bulb shown in Fig. 6 was tried, but even though it was used with success on a well-known

make of engine, it was found to be rather smoky. Further, the fact that a certain proportion of the air in the passage leading into the bulb furthest away from the jet cannot be directly attacked by the oil jet would, no doubt, tend to keep down the main pressure.

The type shown by Fig. 7 easily gave the best results despite possibly some serious drawbacks. With paraffin, shale oil and gas oil the exhaust was perfectly clean, full power was obtained without assistance of the water-drip, and no overheating of the bulb took place. With the water-drip an increase of 25 per cent in the power was easily maintained for long periods and without the expenditure of any additional fuel oil. The writer believes that this type of bulb keeps cool without the water drip, because the whole of the flange of the bulb is in contact with the water-cooled cover.

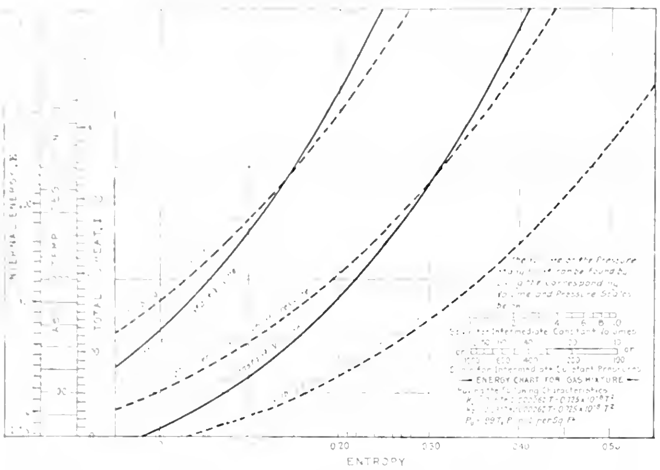

Fig. 8 Combined Chart of Entropy Temperature (ϕT) and Entropy-Total Heat (ϕI)

Should the bulb tend to keep too cool, its temperature can be nicely adjusted by relieving some of the flange, so as to reduce the surface in contact with the water cooling of the cover. The bulb proved to be very durable.

Two modifications of Fig. 7 were tried: one in which the nozzle was placed in the cylinder cover and much nearer to the bulb than in Fig. 7, and another with the bulb having one of the walls practically a prolongation of the throat to the cylinder. Both proved to be failures. Next, the nozzle was put directly in the bulb with no better success. The difference in the design of these types of bulbs is quite slight and is a good illustration of how small the margin is between success and failure in the design of hot-bulb engines. (*The Engineer*, vol. 124, no. 3215, Aug. 10, 1917, pp. 112-113, 6 figs., *d*A)

An Energy Diagram for Gas Mixtures and Some of Its Uses, William Alexander

Charts have been published for the average gas mixture in metric units, namely, by Prof. A. Stodola, but these charts can not be used with British units of pressure and volume. In view of these facts the writer prepared a chart expressed in British units and represented in it all of the six state characteristics of gaseous substances.

In the derivation of the chart and expression of equations on which it is based, the following notation has been used:

P = pressure in lb. per square foot, or

p = pressure in lb. per square inch

v = volume in cubic feet per lb.

T = absolute temperature (centigrade)

ϕ = entropy

E = internal energy

I = total heat, defined by $I = E + \dfrac{Pv}{J} = E + A\,Pv$, where

$J = \dfrac{1}{A}$ = Joule's equivalent = 1,400 ft-lb. per pound-degree centigrade.

The writer derives expressions for the various relations, of which the following are cited here.

Relation between the Entropy and Temperature for the Constant-Volume and the Constant-Pressure Lines. For any constant-volume line, the difference between the entropies at any two temperatures T_2 and T_1, is

$$\phi_2 - \phi_1 = b \log_e \frac{T_2}{T_1} + s(T_2 - T_1) - \frac{u}{2}(T_2^2 - T_1^2)$$

and for constant-pressure lines

$$\phi_2 - \phi_1 = a \log_e \frac{T_2}{T_1} + s(T_2 - T_1) - \frac{u}{2}(T_2^2 - T_1^2)$$

Also, at any given temperature the difference of entropies for the constant-volume lines v_1 and v_2 is

$$\phi_2 - \phi_1 = R \log_e \frac{v_2}{v_1}$$

and for constant-pressure lines P_1 and P_2 is

$$\phi_2 - \phi_1 = -R \log_e \frac{P_2}{P_1}$$

also

$$\phi - \phi(p = 14.7) = 0.0707 (\log_e p + \log_e 14.7)$$

where p is now in lb. per square inch.

On the chart entropy is set off horizontally on an even scale, and an even scale of temperature and uneven scales of total heat and internal energy are set off vertically.

The author discusses in some detail the advantage of representing the six functions of state as a means of simplifying the expressions.

But, besides simplifying the calculation in finding the efficiency of ideal diagrams, the energy chart affords a convenient means of ascertaining, to some extent, the kind of thermal action that goes on in the cylinders of actual gas engines and enables one to obtain a fairly close idea of actual efficiencies.

The writer also shows how the mean pressure can be determined from or checked by means of a practical thermal diagram, which latter gives at once the temperatures at most points of the cycle. In particular, the writer carries through a comparison between a small and large Diesel engine, and finds through a consideration of the compression lines that the larger cylinder and piston are hotter than the smaller. The hot cylinder may account for earlier and better combustion in the larger engine, as the expansion lines on the right (Fig. 9) would indicate. The average temperature of the cylinder and piston surface in the larger engine is seen from the figure to be approximately 750 deg. cent. absolute at the point H, which temperature is near the limit for the best lubricating oils. This indicates the reason for the well-known particular difficulty experienced in keeping cool the piston and internal surface of the cylinder of large Diesel engines.

The nature of the combustion is also well illustrated in Fig. 9. In the larger Diesel engine combustion is nearly complete at 0.4, equivalent to 0.36 of the stroke, and in the small Diesel combustion is almost complete at 0.7 equivalent, to 0.46 of the stroke. The thermal diagram should therefore be of consider-

able service in tuning up engines to give their best indicated results. (*The Journal of the Institution of Mechanical Engineers*, no. 5, July 1917, pp. 333-349, 8 figs., *tA*)

Measuring Apparatus

Theory of the Flexible-Tube Manometer, H. Lorenz

(*Phys. Zeits.*, vol. 18, pp. 117-121, March 15, 1917)

For measuring the pressure of liquids or elastic fluids in industrial processes, the Bourdon flexible-tube manometer plays an important part. The active component of this instrument is a thin-walled metallic tube of oval, i.e., elliptical, cross-section, which is bent into circular shape, the ring, however, not being closed but including an angle of 270 deg. Both ends are closed by soldered covers, and near the fixed extremity the tube carries a support for attachment to the vessel under examination. Pressure causes deformation of the tube, which deformation is communicated to a calibrated recorder fixed to the movable end.

The present paper deals with the theory of this instrument, and first investigates a closed-ring tube possessing a known internal pressure. A previous paper [see Abs. 1335 (1912)] on the bending of curved tubes should be consulted. The distortion produced is found to be directly proportional to the pressure in the flexible tube—a fact which supersedes the previous theory of dependence upon the strength of the tube. Discrepancies between theory and experiment are ascribed to the incomplete elliptical shape of the meridian curve or to the loss of double symmetry of distortion. (*Science Abstracts*, Section A—Physics, vol. 20, part 7, July 30, 1917, no. 235, p. 258, *et*)

Mechanics

Column Tests and Formulæ, Robert S. Foulds

In the *Engineering News-Record* of June 28, 1917, was given a description of column tests made at the Bureau of Standards. The present article is partly of the nature of comments.

The writer expresses the belief that on account of the erratic tests it is idle to expect plotted results of any particular series of one cross-section to give a smooth curve for a column formula. Further, with erratic results eliminated, different sections with ends squared, as in the Bureau of Standards tests, would probably have varying degrees of end fixity, and this would give curves of different slopes.

The general trend of these tests, as a whole, is seen to follow the direction of the formula 36,000-0.386 $(l/r)^2$, tangent to the Euler curve $\frac{28E}{(l/r)^2}$ at $l/r = 216$. Perfect fixity of the ends is not to be expected—that is, a curve tangent to $4\,\frac{\pi^2 E}{(l/r)^2}$. In column tests with pin ends, one would expect a general slope such as is expressed by a curve tangent to $16\frac{E}{(l/r)^2}$, which end conditions it is believed approximate the end conditions in structures. Had the length l between points of inflection in these tests been measured and the results plotted, they would probably have had the general slope of a curve tangent to $\frac{\pi E}{(l/r)^2}$

The writer believes that too few tests have been made to establish any formula, and besides no one formula for a steel of particular chemical combination would exactly express the facts for various sections and for thin and thick material.

He further believes that had the elastic limits been given, it would have probably been found that the ratio of the elastic limit of the columns tested to their ultimate is roughly equal to the ratio of the elastic limit of full-sized tension members to their ultimate.

As regards working stresses, he claims that a curved-line formula is more rational than a straight-line formula, and believes that in time engineers will adopt a curved-line formula something like the J. B. Johnson parabolic formula, or

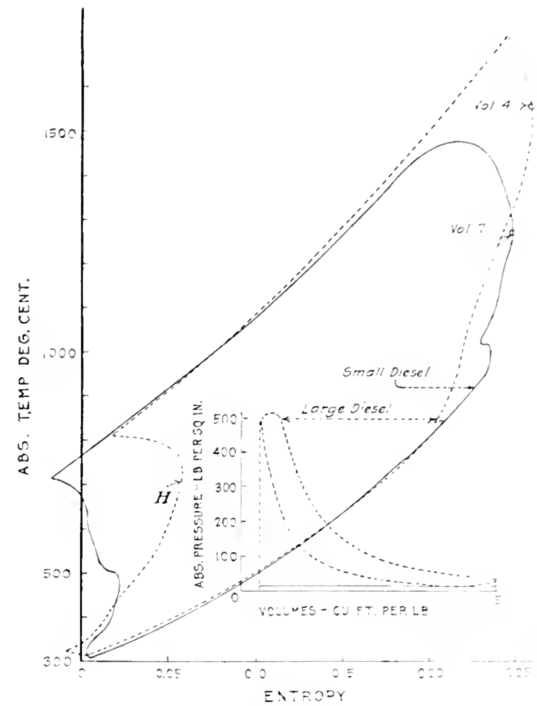

Fig. 9 Comparison of Thermal Diagrams for Large and Small Diesel Engines

36,000—0.7 $(l/r)^2$. (*Engineering News-Record*, vol. 79, no. 6, August 9, 1917, pp. 260-261, *e*)

Standardizing Symbols for Screw-Thread Notation and Formulæ

The Bureau of Standards is considering the symbols given below for use in its work on the standardization of screw-thread gages. In proposing the particular letters given, several points have been in mind, such as the use of symbols which can be found on the ordinary typewriter, and the consistent use of large and small letters.

An attempt has been made to use the large and small letters in a systematic manner which will give the best results. In computations and development formulæ, it is generally most convenient to use the diameter. It has, therefore, seemed desirable to provide symbols for both diameters and radii, and this has been done by using the large letters for the diameters and the corresponding small letters for the radii.

With a few exceptions, the capital letter has been used to indicate the largest quantities and the small, or lower-case, letter the corresponding smaller quantities. This has not been done in the case of the letter "N," as it was thought best to have the upper-case "N" a reciprocal of the upper-case "T," and similarly with the lower-case "n" and "t." The

Bureau will be very glad of constructive criticisms and suggestions from those who are experienced and interested in the subject. The symbols follow:

SYMBOLS FOR SCREW THREAD FORMULÆ

Full, or outside diameter	D
(Corresponding radius)	d
Pitch or effective diameter	E
(Corresponding radius)	e
Core diameter	K
(Corresponding radius)	k
Angle of the thread	A
(For half the angle)	a
Number of turns per inch	N
Number of threads per inch	n
Lead	P = 1/N
Thread interval	p = 1/n
Helix angle	s
Tangent of the helix angle	S
Width of flat at top and bottom	F
Distance from the flat to point that would be formed if sharp V-thread were used	f
Depth or height of sharp V	H
Depth or height of thread	h

REGARDING WIRE MEASUREMENTS

Measurement over wires	M
Diameter of wire	G
(Corresponding radius)	g
Radius of curvature (Whitworth crest and root)	c

(*American Machinist*, vol. 47, no. 8, August 23, 1917, p. 326, *g*)

Pumps

Notes on the Construction of Turbine Pumps, Alan E. L. Chorlton, Mem. Am. Soc.M.E.

Description and discussion of the main elements of construction of turbine pumps. The writer considers the subject under the headings of the various component parts of a pump. These are:

The *stator*, which consists of the casing, or housing, and of the guide vanes, or appliances, for converting velocity energy into pressure energy.

The *impeller*.

The *balancing appliances*, hydraulic or mechanical.

The *rotor* considered as a whole, and including the spindle, with its protecting sleeves, impellers, and, in most cases, the balancing appliances.

The *bed* and other details, bearings, stuffing boxes, etc.

There are two main types of casings: the Osborne-Reynolds, or divided type, sometimes called the ring type, and the Sulzer integral, or one-piece type, sometimes called the cylindrical type. Recent American practice provides a variation of this type with the housing in halves, divided on the horizontal central line.

As regards the guide vane, the writer classifies the various assemblies, or passages, into three groups:

a tangential and radial with return radial
b tangential and spiral
c combinations.

Speaking generally, combination designs are not so efficient as the simple types, owing, probably, to the hydraulic loss through changing the radial direction of the water at high speed.

As regards the finish of guide-passage surfaces, the writer states that for best efficiency, the throat of the passage, at least, if not the entire passage, should be of gun metal or bronze, as iron does not preserve a sufficiently good surface for high-velocity conditions. For best results, a bronze blade should be provided with boxed-in passage, the blade being attached to the guide-vane casting or doweled to the casing.

Impellers are either single-entrant or double-entrant.

Multicellular pumps use a single-eye wheel in three forms: *a*, unbalanced, and equal side areas, one rubbing shoulder; *b*, unbalanced, equal side areas, two rubbing shoulders; and *c*, balanced on paper. Type *c* has the paper advantage of being in balance. Actually it is a poor approximation to a balance. Disturbing factors are set up by differences in side pressure on the impeller due to differences in volume and surface form of the water contained on the two sides of the impeller; by differences of quantitative leakage through the two shoulders, and by high-pressure leakage into one side of the impeller from the stage above and leakage from the other side of the impeller to next low-pressure stage below. Therefore, in practice it is necessary to provide an additional end-balancing device of the hydraulic type, or a mechanically positioning fitting, such as a thrust collar or ball bearing.

The writer discusses in detail the question of how the internal design of all impellers is governed by the two controlling features: the entrance, or inlet angle of vane, and the delivery, or exit angle of the vane.

The balancing appliances are discussed in detail.

As regards the rotor, the question of support is discussed in an interesting manner. The ideal condition is that of a rotor supported in lubricated bearings on a shaft of such sufficient stiffness between supports that the deflection under all possible running conditions is less than the clearance allowed at the neck rings and intermediate bushes, so that no contact takes place between the rotating and the fixed members, this clearance at the neck rings and intermediate bushes being kept down to the smallest possible limits. It is practically impossible to present mathematically the exact conditions with such a number of incalculable factors to take into account.

The supporting effect of the bushes on the shaft in passing through the diaphragm intermediate between the impellers is very difficult to allow for exactly. Intermediate bushes can only, in some cases, be considered as water-lubricated supports, which will act as such so long as a certain low surface pressure on them is not exceeded; but if too great pressure comes on, heating takes place on account of the high-speed of rotation. The author believes that too much use is made of these intermediate supports in turbine-pump design. It is found in practice that an internal bearing to be successful must have the same water pressure at both ends and must be properly lubricated with good grease, and then it gives excellent results. It is, after all, a fact, therefore, that designers are practically dependent on the shaft itself for the necessary strength and stiffness to allow of vane internal clearance, which makes apparent the great importance of a good design which will economically give the minimum deflection of the spindle.

The forms of neck-ring are classified and discussed under the following heads:

a Internal
b External
c Vertical
d Labyrinth

The factors affecting the deflection of a turbine-pump spindle are:

Static
- (*a*) The weight of spindle and distribution of diameter change
- (*b*) The weight and distribution of impellers, balancer, and parts
- (*c*) The number and span of supporting bearings; and

Dynamic
- (*d*) The dynamic condition, other incalculable forces entering into the account, such as centrifugal forces due to the out-of-balance masses, and finally certain hydraulic disturbances.

(*a*) Should be as light as possible consistent with the necessary stiffness, and in common practice spindles are practically parallel the whole length.

(*b*) Impellers and balancer should be grouped together as closely as possible, only allowing sufficient space for the water passages between the stages; also, the entire weight should be brought as close to the supporting bearings as possible.

(*c*) The span of supporting bearings plays such an extremely important part in the durability of the pump; in the possibility and preservation of fine clearances; in the whirling of the shaft and in the determination of the most economical size of spindle, that special notice will be taken of it.

(*d*) A loaded shaft supported horizontally between two bearings will "sag," and when rotated must suffer bending at every revolution. Also, there are bound to be certain out-of-balance masses in the rotor due to keys, heterogeneous composition of material, the unavoidable variation of thickness of castings, etc. In addition, a shaft has vibrational periods due to its length and diameter, the whole question of vibration being intensely complicated by the loading and supports. (*Journal of the Institution of Mechanical Engineers*, No. 5, July 1917, pp. 361-432, 42 fig., *cdA*)

Railroad Engineering

Beach Oil-Electric Car for the Nashville, Chattanooga & St. Louis Railway

Description of an oil-electric car designed to supplant steam-locomotive passenger service in branch-line territory where the slight density of traffic makes such a type preferable. This car is provided with motor-driven trucks, current for which is secured from an oil-engine-driven generator mounted in the forward end of the car. It is stated to be the most powerful self-propelled unit of its kind thus far constructed and is expected to operate at from one-third to one-fifth of the expense required to maintain a corresponding service by steam, in addition to its eliminating smoke, etc.

The power plant consists of a four-cycle eight-cylinder 150-hp. engine direct-connected to a 100-kw. differential-compound-wound 250-volt direct-current generator, running at a constant speed of 1,000 r.p.m.

The engine burns a fixed gas derived from a gas generator which operates on kerosene oil. The gas is supplied directly from the generator into the engine cylinders in the proportion of one part of gas to six parts of air.

The car weighs 113,000 lb. completely equipped, accelerates at a rate of 0.8 miles per hr. per sec. and has a speed of 45 miles per hr. It requires 140 hp. to operate this car at 45 miles per hr. and 340 hp. to accelerate at the above-mentioned rate. As the engine generates 150 hp. and the car when running at 45 miles per hr. consumes only 140 hp., the additional power developed is automatically used to charge the battery.

The car is heated by means of hot water from the engine, which is by-passed when not wanted. The double trucks on which the car is mounted are of the equalized high-speed type with 7 ft. 3-in. wheel base, 33-in. M.C.B. rolled-steel wheels and 5 x 9-in. M.C.B. journals.

The following is believed to be a fair average cost per mile (the cost generally varies with the service required): Wages, \$0.0745; fuel and lubrication, \$0.04; repairs and supplies, \$0.035; depreciation, \$0.0385; total cost, \$0.188. (*Railway Review*, vol. 61, no. 9, September 1, 1917, pp. 259-260, 3 figs., *d*)

A 120-Ton Coal Car for the Virginian Railway. B. W. Kadel

Description of one of four experimental cars built for the Virginian Railway without drop doors to unload in the car dumper.

The car is built for use in bituminous-coal-carrying service and has certain features of construction which make it of particular interest.

The car body is of plate-and-angle construction, with Carnegie cross-tie sections for side stakes and end-plate stiffeners. The principle of design is that the weight of the lading be actually transferred to the sides of the car, the integrity of the center sill as a draft member being maintained. The center sill extends not quite to the bolster at either end of the car. The buffing forces are delivered to the center sill, not through the rivets, but as direct loads upon the ends of the sills, and the center plates are integral parts of the steel castings forming a portion of the radial draft gear.

To prevent the center sill from receiving bending stresses of any moment from the lading, three plate-girder diaphragms are provided to carry the load out to the side plate girders. These have the compression members passing continuously over the center sill, and the bottom, or tension, member passing under the sill.

The sides of the car are carried by the body bolsters, which are of novel construction. They are integral steel castings located above the floor of the car within the coal space, and are shaped not only to give an economic and advantageous disposition of the metal for the various conditions of load application, but, at the same time, to offer no obstruction to the coal in dumper. Wing plates extend upward from the outer ends of the bolsters to stay the sides of the car.

Because of the great weight of the car, it has been found necessary to provide definite jacking points specially designed to take care of this operation. Two jacking blocks are provided at each corner of the car, either of which will support

TABLE 1 STRESS LIMITATIONS OBSERVED IN DESIGN OF VIRGINIAN 120-TON COAL CAR

	Stress, lb. per sq. in.		
	Structural Parts	Steel Castings	Rivets
Tension	13,000	9,000	. . .
Compression	13,000	9,000	. . .
Shear	9,000	8,000	8,000
Bearing	. . .	. . .	16,000

the load of that corner of the car, so that the car can be jacked up at one of these points and stooled at the other. One of these blocks is under the end of, and in reality a part of, a cast steel body bolster, the other being a part of the corner poling pocket. The push-pole pockets also have bracket portions which extend out and engage stops on the cradle of the dumper, should the overhead clamps for any reason fail to hold the car when in inverted position.

It is stated that the aim in the design has been to eliminate, as far as possible, all useless metal, and to this end an especially careful analysis of the known forces and stresses was made. Under the most extreme conditions of loading the extreme combined stresses have not been allowed to exceed those given in Table 1, based on 10 per cent overload in the car. As far as possible, the secondary stresses have been analyzed and allowed for. The article contains a promise of publishing, at a later date, the method of calculation of stresses for the various portions of this car. (*Railway Age Gazette*, vol. 63, no. 7, August 17, 1917, pp. 285-289, 7 figs., *d*)

Steam Engineering

EXCHANGE OF BASES IN PERMUTITE, Miss G. Kornfeld (*Phys. Zeits.*, vol. 18, pp. 113-114, March 1, 1917. Paper read before the Deutsch. Bunsen Gesell., Dec. 1917.)

Together with V. Rothmund, the author investigated the aluminate-silicates, or permutites, of Gans, considering them to consist of two phases, a solution containing two cations and one anion, and a solid phase (permutite) containing the two cations. The author reviews the researches and formulæ of Wiegner and of Gans, and describes experiments in which powdered sodium permutite was mixed with solutions of silver nitrate and sodium nitrate (simultaneously or separately), and shaken for about five minutes; the concentrations varied within very wide limits. A new formula is deduced and tested by experiments with silver permutite and alkali salts. (*Science Abstracts*, Section A—Physics, vol. 20, part 7, July 30, 1917, no. 235, pp. 301-302, *gt*)

SUGDEN'S SUPERHEATER FOR THE STIRLING TYPE OF BOILER

In the usual arrangement of superheater with this type of boiler the former is placed between the first and second bank of tubes. There are, however, certain particular objections to this arrangement, principally because of the very limited space available for cleaning, removing or replacing either boiler or superheater tubes.

If the superheater is arranged with the headers either above or below the two sets of circulating pipes connecting the steam and water space of the drums, there are certain difficulties; if placed below the expanded joints of the tubes and the joints of the handholes affording access to the headers, they are in the path of the flame and heated gases, which is bad practice. In the alternative arrangement the headers are placed outside the superheater pipes, being inserted between the circulating pipes. This is the objectionable feature of placing the superheater tubes in the chamber between the first and second banks of tubes, as this increases the difficulty of taking out and replacing the boiler tubes as well as the superheater tubes.

In the new design, shown in Fig. 10, the superheater is placed in the first chamber, in close contact with the front wall of the boiler and in such a position that access can be readily obtained for cleaning and inspection. It also avoids any complications in removing either boiler or superheater tubes.

Such an arrangement involves the danger of having the superheater projecting too far into the chamber and burning out. In this case this difficulty was overcome by placing the superheater tubes in a single header so arranged that the front and back rows were not more than about four inches apart, which prevents any excessive heat reaching the tube.

The superheater header is divided into three compartments and consists of two double groups of U-tubes, one group being placed immediately alongside the other.

If a superheater tube should fail, it is not necessary to shut the boiler down, as the tube can be plugged in a few minutes. For this purpose a steam stop valve is placed on the inlet side of the superheater, so that it is only necessary to discharge the steam from the superheater to reëxpand or stopper a tube, which can be done in a few minutes without letting the steam out of the boiler.

The following particulars are given of the working of this

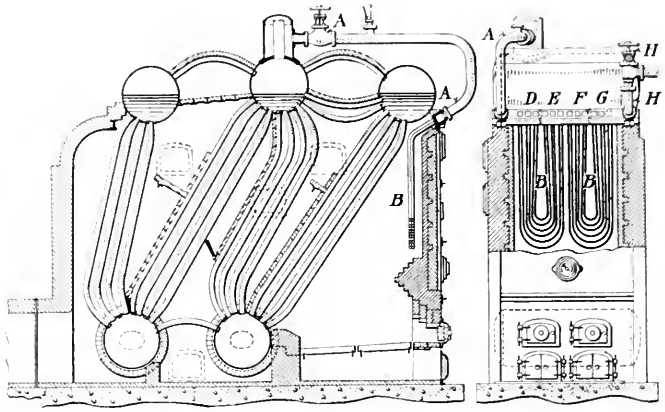

FIG. 10 SUGDEN SUPERHEATER FOR STIRLING TYPE OF BOILER

superheater on a Stirling boiler at the Blaina Colliery. The boiler has a heating surface of 1620 sq. ft. and a grate surface of 32 sq. ft. and is capable of evaporating under normal conditions of working about 6500 lb. of water per hour. The working pressure is 160 lb. per sq. in., giving a temperature of 370 deg. fahr. The superheat added to the steam at this temperature is 180 deg. fahr., making a total steam temperature of 550 deg. fahr. (*Engineering*, vol. 104, no. 2693, Aug. 10, 1917, p. 147, 3 figs., *d*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

The thirty-fifth Annual Convention of the National Association of Stationary Engineers was held at Evansville, Ind., September 10 to 14. The business session included an enlightening paper on How Manual Training Became Vocational Training. This was followed by an appreciative lecture commemorating the one-hundredth anniversary of George Henry Corliss, the inventor of the Corliss engine.

PERSONALS

IN these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by October 16 in order to appear in the November issue.

CHANGES OF POSITION

M. A. NEELAND has been elected president of the New York Shipbuilding Corporation, Camden, N. J.

G. C. HYDE, formerly engineer with the Kentucky Utilities Company, Louisville, Ky., has entered the service of the Southern Indiana Power Company, Bedford, Ind.

J. CLYDE PARMELY, superintendent of the St. Clair County Gas and [illegible] Company, Belleville, Ill., has become identified with the [illegible] Gas and Electric Company, Plymouth, Pa.

[illegible], until recently connected with the Remington Arms Company, Chester, Pa., as superintendent, has become associated with the [illegible] Manufacturing Company, of New York.

[illegible] M. S[illegible], located at Dozey, N. D., has recently [illegible] with the Sheyenne Valley Light and Power Company, [illegible] Valley City, N. D.

DANIEL E. KEHOE, formerly associated with Kehoe's Iron Works, Savannah, Ga., is now located at the Charleston Navy Yard in the hull division as assistant shop superintendent.

W. L. BEAN, who has been acting as assistant to the president of the N. Y., N. H. and H. R. R. Company, New Haven, Conn., has been appointed assistant to general mechanical superintendent.

GEORGE W. WILDIN, general mechanical superintendent of the N. Y., N. H. and H. R. R. Company, New Haven, Conn., has been appointed general manager of that company, succeeding C. L. Bardo.

GUY C. PITTS, formerly assistant to yard engineer, Sun Shipbuilding Company, Chester, Pa., has entered the service of the Federal Shipbuilding Company, New York, as assistant mechanical engineer.

JOHN E. LOVELY has severed his connection with the Fort Dearborn Manufacturing Company, Sterling, Ill., and has accepted a position with the Vermont Farm Machine Company, of Bellows Falls, Vt.

ARTHUR B. NEWHALL, formerly instructor of applied science at Wentworth Institute, Boston, Mass., has become identified with the Hood Rubber Company, Watertown, Mass.

F. J. RYAN resigned from the Snyder Electric Furnace Company on June 1, to take up the duties of general manager of the Electric Furnace Construction Company, Philadelphia, Pa.

John A. Randall, head of the department of physics at Pratt Institute, Brooklyn, N. Y., has resigned to enter the employ of the Toledo Scale Company in an engineering capacity.

R. Burdette Dale has resigned as chief engineer of the Erie City Iron Works, Erie, Pa., and has accepted a position in the planning department of The Franklin Manufacturing Company, Franklin, Pa.

John J. Harman, assistant chief engineer with the Elliott and Harman Engineering Company, Peoria, Ill., has become affiliated with the Walworth Manufacturing Company, of Kewanee, Ill.

Max M. Shaw has become affiliated with the Merchant Mill of the Bethlehem Steel Company, South Bethlehem, Pa. He was formerly connected with Wentworth Institute, Boston, Mass.

Charles J. Bamford, formerly affiliated with the Agasote Millboard Company, Trenton, N. J., as chief engineer, has become associated with the Buffalo Cold Storage Company, of Buffalo, N. Y.

J. G. Malone has accepted a position as engineer with The Roessler and Hasslacher Chemical Company, Perth Amboy, N. J. He was until recently connected with the Hercules Powder Company, of Parlin, N. J.

Arthur C. Hubbell, formerly machine designer with C. D. Enochs, of Minneapolis, Minn., has become identified with the Purchasing Bureau of Small Arms, New York, in the capacity of United States inspector.

J. B. Freeman has resigned his position as chief engineer of the Webster Engineering Company, Chicago, Ill., and has accepted a similar position with the Du Pere Manufacturing Company, of the same city.

George J. Sturmfelsz, Jr., has resigned the position of boiler house engineer with E. I. duPont de Nemours and Company, City Point, Va., to accept the position of superintendent of boilers with the Bethlehem Steel Company at their Sparrows Point, Md., plant.

Henry Swift has severed his connection with The American Steam Gauge and Valve Manufacturing Company of Boston, Mass., and is now associated with The Cincinnati Ball Crank Company, of Cincinnati, Ohio, as chief engineer.

James P. Calderwood has resigned as associate professor of mechanical engineering in Pennsylvania State College, State College, Pa., and has accepted a position in the technical research department of the Travelers Insurance Company, Hartford, Conn.

James T. Gratiot has severed his connection with Fairbanks, Morse and Company, Denver, Colo., as manager of the machinery department, and has assumed the duties of manager of the Coliseum Garage Company, Casper, Wyo.

Alton A. Richardson, until recently identified with the Castner Electrolytic Alkali Company, Niagara Falls, N. Y., in the capacity of assistant engineer, has accepted the position of engineer with the National Electrolytic Company, Canal Basin, Niagara Falls, N. Y.

Roland F. Hetzel has resigned his position as shop instructor in the Seattle Public Schools, Seattle, Wash., to accept a position in the engineering department of the Ames Shipbuilding and Drydock Company, of the same city.

Clarence P. MacArthur, for the past five and a half years master mechanic of the Bowen Manufacturing Company, of Auburn, N. Y., has resigned to accept the position of general foreman with the Wagner Electric Manufacturing Company, of St. Louis, Mo.

Burton C. Fonda has become affiliated with the New York office of The F. W. Horne Company, of Tokio, Japan. He was formerly connected with the turbine department of the General Electric Company, Schenectady, N. Y.

J. E. Gibson, formerly in the employ of the American Pipe and Construction Company, Philadelphia, Pa., as principal assistant engineer, has assumed the position of manager of the water department of the Charleston Light and Water Company, Charleston, S. C.

W. S. Jones, of Philadelphia, who has been associated with the Midvale Steel Company in its general sales department, has been chosen vice-president of the Vanadium Alloys Company, of Pittsburgh, Pa.

George M. Smith, until recently associated with Walter Rachals and Company, Youngstown, Ohio, as chief engineer, has become connected with the Interstate Iron and Steel Company, Chicago, Ill., in a similar capacity.

Louis M. Zach, formerly mechanical engineer and designer with the Anaconda Copper Company, and International Smelting Company, Tooele, Utah, has accepted a similar position with the Public Works office, Washington Navy Yard, for the period of the war.

Donald C. Wright, formerly production manager of the Remington Arms-Union Metallic Cartridge Company, Ilion, N. Y., in charge of Enfield contracts, has become affiliated with the Dodge Manufacturing Company, Mishawaka, Ind., in the capacity of production manager.

J. N. Helpbringer has resigned from the position of power-plant engineer with the Firestone Tire and Rubber Company, Akron, Ohio, to accept the position of superintendent of power plants with the Kansas Gas and Electric Company, with headquarters at Wichita, Kan.

G. G. Crewson, until recently connected with the Roessler and Hasslacher Chemical Company, Perth Amboy, N. J., as mechanical engineer, has become associated with E. I. du Pont de Nemours and Company, Wilmington, Del., in a similar capacity.

Robert H. Wallace has entered the employ of the Alignum Products Company, South River, N. J., in the capacity of factory manager. He was formerly shop superintendent of the Bailey Meter Company, Cambridge, Mass.

Frank E. Wilder, who has been consulting engineer with the Southwark Machine Company, of Portland, Me., for some time, will remove to Bristol, Conn., where he has taken a position on the engineering staff of the New Departure Manufacturing Company.

Ben. G. Elliott, until recently associate professor of mechanical engineering at the University of Nebraska, Lincoln, Neb., has become affiliated with the University Extension Division of the University of Wisconsin, Madison, Wis.

Edmund Barany, machine designer of the Singer Manufacturing Company, Elizabeth, N. J., has assumed the duties of mechanical engineer and assistant to general superintendent of the Cleveland Twist Drill Company, Cleveland, O.

R. J. S. Pigott, New York district manager for Sanford Riley Stoker Company and B. F. Sturtevant Company, has become identified with the Bridgeport Brass Company, Bridgeport, Conn., as superintendent of the raw-material departments.

Frederick W. Gay, formerly associated with The J. G. White Engineering Corporation, San Francisco, Cal., has assumed the position of general manager of the New York office of the Pelton Water Wheel Company.

Charles L. Fischer has accepted the position of master mechanic with the Willard Storage Battery Company, Cleveland, Ohio, after twelve years of service with the Pennsylvania Lines West of Pittsburgh.

Ernest O. Hickstein, recently identified with the U. S. Indian Service, Pawhuska, Okla., as natural-gas engineer, has again become affiliated with the Empire Gas and Fuel Company, Bartlesville, Okla., in the research department.

Edward R. Feicht, formerly master mechanic of the Federal Dyestuff and Chemical Company, Kingsport, Tenn., has assumed the duties of assistant superintendent of plant of the Bridgeport Brass Company, Bridgeport, Conn.

Charles J. Manuel, formerly chief draftsman of the tool department of the Aeromarine Plane and Motor Company, Keyport, N. J., has become affiliated with the forging department of the American Can Company, Edgewater, N. J., in the capacity of chief draftsman.

Maurice L. Bullard has entered the employ of L. H. Shattuck, Inc., agents for the U. S. Shipping Board, Emergency Fleet Corporation, in the construction of a ship yard and also the building of wooden hulls. Mr. Bullard was recently associated with the W. H. McElwain Company, Manchester, N. H., in the capacity of chief engineer.

Henry C. Berrian, until recently connected with the engineering department, estimating division, of the Newport News Shipbuilding and Dry Dock Company, Newport News, Va., has become affiliated with the Federal Shipbuilding Company, New York.

R. A. Smart, formerly assistant manager of works of the Westinghouse Electric and Manufacturing Company, and later in charge of the American and Canadian plants of the Oliver Chilled Plow Works as works manager, is now associated with the Tacony Steel Company and the Tacony Ordnance Corporation, of Tacony, Philadelphia, Pa.

Harry J. Klotz has obtained a leave of absence from his position as operating engineer for the Decatur Railway and Light Company, Decatur, Ill., and has accepted, for an indefinite period, the position of instructor in the School of Aeronautics which the University of Illinois is conducting for the Government at Champaign.

ANNOUNCEMENTS

[illegible] been commissioned captain in the Engineer Offi[illegible]

[illegible] entered the employ of the Lehigh Navigation Electric Company, Allentown, Pa.

[illegible] has become associated with the Carrier Engineering Corporation, New York.

The partnership between H. K. Beach and Paul C. Phillips, under the name [illegible] and Beach, Philadelphia, Pa., has been dissolved.

[illegible] Merritt has assumed the duties of employment super[illegible] Company, Ltd., Grand Mere, Quebec, Canada.

J. [illegible] Johnson, Jr., of New York, has gone to the Pacific Coast on a professional trip which will require six or seven weeks.

Lawrence E. Webster, secretary of the Western Ohio Railway Company, with headquarters in Cleveland, Ohio, has been commissioned as Captain, Ordnance Department, U. S. A.

Cornelius L. Myers has gone to Washington at the request of Quartermaster General Sharpe to assist in standardization and design of motor trucks to be used by the Army.

Herbert B. Reynolds has become identified with the United Railways and Electric Company, Baltimore, Md., in the capacity of mechanical assistant to the superintendent of motive power.

John B. Price, formerly connected with the Chicago, Ill., office of The Mechanical Appliance Company, of Milwaukee, Wis., as sales engineer, has opened an office for the same company at Cincinnati, Ohio.

W. F. Firth, safety engineer for a number of years with the Midvale Steel Company, Philadelphia, Pa., has resigned to take a well-earned vacation.

E. F. Rich, whose firm, Neiler, Rich and Company, have been selected as supervising engineers in charge of the heating for Camp Custer Cantonment at Battle Creek, Mich., will be located there until the completion of the work.

John A. Stevens, Manager Am.Soc.M.E., engaged in consulting engineering with steam-power plants as a specialty, at Lowell, Mass., has organized a department to cover the design and superintendence of construction of factory buildings.

Harry J. Marks, formerly with the American Engine and Electric Company, New York, which has recently been purchased by the Bound Brook Engine and Manufacturing Company, is now in charge of the New York office of the latter company. Mr. Marks for the past ten years has been instrumental in installing numerous steam plants.

It was erroneously stated in the September Journal that A. R. Dickinson was no longer in the employ of Lockwood, Greene and Company. Mr. Dickinson is still connected with the mill management department of that company, and is temporarily located at the Winnsboro Mills, Winnsboro, S. C.

Captain William T. Taylor has been appointed a permanent captain in the British Army with seniority from June 1, 1916. For the past nine months he has been attached to the Royal Flying Corps. In the early part of 1915 he resigned his position in Bolivia, S. A., to join the British forces. Since 1916 he has been engaged on the French front.

Frank L. Ellis, who was engaged by the Jones and Laughlin Steel Company, Pittsburgh, Pa., to design, build and put into operation a new mill at Woodlawn, Pa., has opened an office as consulting engineer in Pittsburgh. For 12 years Mr. Ellis was chief engineer of the [illegible] Engineering and Foundry Company, Pittsburgh, and later was [illegible] of the Mark Manufacturing Company, of Chicago, [illegible]

APPOINTMENTS

[illegible] Kilpatrick, N. G., N. J., who constructed Camp W[illegible] Major in the regular service, his [illegible] immediately.

[illegible] has been commissioned a Captain of the En[illegible] Corps of the United States Army, and placed [illegible]

Robert G. Bennett, recently assistant engineer of motive power of the central division of the Pennsylvania Railroad Company, Williamsport, Pa., has been appointed master mechanic of the Pennsylvania Railroad Shops at Sunbury, Pa.

Louis T. Klauder has been appointed construction engineer of the Philadelphia Rapid Transit Company, Philadelphia, Pa., superseding William C. Kerr, who has recently become associated with the Republic Railways and Light Company, New York.

Clarence S. Adams has been appointed assistant superintendent of inspection of the Pierce-Arrow Motor Car Company, Buffalo, N. Y. He was formerly connected with the same company in the capacity of engineer.

H. E. Harris and William A. Viall have been appointed members on a committee to act with the National Bureau of Standards in producing gages for the manufacture of munitions and standardized parts for small arms and heavy ordnance.

Walter E. Dunham, until recently connected with the Chicago and North Western Railway Company, Winona, Minn., in the capacity of supervisor of motive power and machinery, has been appointed assistant to the general superintendent of motive power and car departments of the same company, with headquarters in Chicago, Ill.

The following appointments have been announced by The Waltham Watch Company, Waltham, Mass.: Olaf Ohlson, formerly mechanical superintendent, is now general superintendent; E. L. Folson, industrial superintendent, has been appointed assistant to the vice-president and given the title of assistant general manager; Gleason Wood, formerly assistant superintendent, has been appointed assistant general superintendent.

Edgar C. Felton, formerly president of the Pennsylvania Steel Company, has accepted an appointment as Director of the Department of Civilian Service and Labor, under the Committee of the Public Safety, Philadelphia. In addition to being connected with various railroads and steel companies, Mr. Felton is now on the board of managers of the Girard Trust Company, and director of the Franklin National Bank and the Farmers and Mechanics National Bank.

AUTHORS

W. Knight is the author of Stresses in Rotating Discs with a Hole at the Centre, which appears in the August 3 issue of *Engineering*.

L. A. Quayle has contributed an article on Coal and Ash Conveyor Tests to the September 4 issue of *Power*.

C. F. Hirshfeld is the author of an article on Efficiencies of Steam-Turbine Cycles, published in the September 18 issue of *Power*.

Carl W. Weiss is the author of an article on Function of Water in Internal Combustion Engines, published in the September issue of *The Automobile and Automotive Industries*.

L. A. Wilson, Urbana, Ill., contributed an article on Lowering the Grade of Gasoline, which is published in the September number of *The Automobile and Automotive Industries*.

Frederick G. Coburn is the author of an article on The Assistant from the Manager's and His Own Viewpoint, which appears in the September issue of *Industrial Management*.

PREVENTABLE WASTE OF COAL IN THE UNITED STATES

With a Consideration of Alternative Methods of Its Elimination

By DAVID MOFFAT MYERS, NEW YORK, N. Y.

Member of the Society

As a means of far-reaching economy the Government of the United States should at this time apply intelligent and direct-acting efforts to the conservation of fuel at the industrial plants which are responsible for its greatest consumption. It is unnecessary before a body of engineers to show proof that coal is wasted in vast quantities in the boiler furnaces of our plants, to feed which it is mined and distributed at a high and ever-increasing cost of labor and material.

The mining and distribution of coal have been placed under the supervision of the War Coal Board in order more nearly to meet the crying needs in these directions, to use the railroad facilities more efficiently so that the present car shortage may be minimized to the greatest possible extent, and to apportion the coal in quantity and to uses deemed most expedient.

While this organized effort to bring about efficiency in the production and distribution of coal is being made, no parallel measures have been adopted to bring about a normal and practicable efficiency in its use. The hundreds of large plants which are consuming fuel wastefully, in many cases more wastefully and carelessly than ever before, are directly and needlessly causing a large fraction of the existing car shortage. They are overloading the already strained capacity of the railroads: they are rendering slower and more difficult the transportation of food and other vital commodities, and in short they are simply counteracting the measures of efficiency in production and distribution which have elsewhere been established.

Comprehensive abstracts of the papers to be presented and discussed at the thirty-eighth Annual Meeting of The American Society of Mechanical Engineers, to be held in the Engineering Societies Building, New York, December 4 to 7, are continued in this issue and will be concluded in the December number.

The abridgments here presented are supplemental to the complete papers being printed in pamphlet form. They have been prepared with the collaboration of authors and are therefore authoritative presentations of the subject-matter of the papers. In many cases the abstract omits only such sections of the complete paper as mathematical derivation of formulae, minute descriptions of apparatus, logs of tests, etc., which could not very well be curtailed.

As stated, all the Annual-Meeting papers appearing in The Journal are also being printed in unabridged pamphlet size for advance distribution, and members of the Society desiring a complete copy of any particular paper may obtain it upon application to the Secretary.

Contributed discussion of these papers for presentation at the meeting and publication in The Journal and Transactions is invited.

PREVENTABLE WASTE OF FUEL

The preventable waste of fuel in the boiler furnaces of one steel mill amounted to 40,000 tons per year, which at \$5 a ton would cost \$200,000. This was a comparatively modern plant. The efficiency of boilers and furnaces in a 14-day test was 55 per cent. The load factor was unusually favorable to high efficiency and could readily be raised to 70 per cent or over. This is only one example and there are many more extreme cases. In one hand-fired plant the evaporation was raised from 6 to 9 lb. in a few days of instruction, and continuously kept close to this higher mark with the help of coal and water measurements which were inaugurated. The saving was due exclusively to instruction and consequent better operation.

The saving or wasting of one-fourth of the coal consumption of any industrial plant depends entirely upon the efficiency of its operating management. Let me emphasize that this fraction of the consumption relates exclusively to the *boiler* plants, i.e., the production of steam; and does not include the large economies possible in connection with its distribution and use.

For well-known reasons the boiler plant offers the more lucrative field for producing economies, and these with a minimum of alteration in physical equipment.

Under present conditions a plant which carelessly operates at an efficiency of 40 to 50 per cent receives from the Government the same consideration in the delivery of coal as the one whose efficiency is 70 to 75 per cent. This obviously is unfair as well as wasteful.

The Government hands over, say, 200,000 tons of coal a year to a plant owner, but asks for no account as regards its consumption, nor any questions as to the amount of steam it is made to produce. There is nevertheless an equivalent amount of steam this fuel is capable of generating, and it can and should be made to produce that quantity.

CONSERVATION METHODS

The object of this paper is to open a discussion which it is hoped will ultimately lead to the formulation of definite recommendations of means for the reduction of the present great preventable waste of fuel in our industries; to direct such means principally toward the elimination of that portion of the present waste which is due to faulty, careless and uninformed operation of plants; to forward these recommendations to the proper governmental authorities as an official com-

For presentation at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 4 to 7, 1917. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

ministration of the Society, and to offer to the Government the services of the Society for the organization, furthering, and, as far as possible, the execution of the plan which may as a consequence be adopted.

In general, there are two plans of operation worthy at least of consideration. One might be termed the autocratic method. This would involve the use of authority to compel coal consumers to execute such measures of economy as the proper authorities might prescribe for any given case. Limits to be set as to expense to the user. Such limits might be in terms of a percentage of their present yearly coal bill. Alterations to be directed chiefly, as previously implied, to purely operating improvements. Many objections would probably be made by consumers against this plan, but once in effect the majority would no doubt realize its pecuniary advantage to themselves. But its tendency may be too strongly opposed to democratic principles.

The other plan would be largely an educational one, in which patriotism and efficiency would furnish the motive forces required.

The teaching must be accomplished with the utmost simplicity and directness. Above all it must be in such form as to be readily comprehended and applied. This is a big task, but with the technical and executive ability represented in this Society, these things should be and can be accomplished.

The requisite information must reach the owners and managers of industries, and there must be simple instruction sheets for the engineers and firemen. The vital importance of daily accurate records of coal and water must be taught and information given regarding practical appliances for automatic measurements of both.

Blank forms might be sent in advance to plant owners in order to be advised by them, first, whether they would be willing to coöperate with a governmental organization offering to assist them in reducing their coal consumption, and second, to obtain such data as to size, type, equipment, operation and fuel consumption of the plants as would enable a classification which would permit a Government board of experts to send such instructions as would include the information needed for any one class of plants.

This work would be greatly aided by a staff of experts ready to visit plants when so requested by owners and make investigations and recommendations and keep in touch with the progress of economies. Included in such a staff should be men intimately familiar with practical operating economies whose duties would be the delivering of lectures or talks, which should be planned so as to reach directly not only managers and owners of the industries, but also the chief engineers and firemen of the boiler plants. This feature of the plan, by itself, would undoubtedly result in great savings.

The U. S. Bureau of Mines has for a number of years engaged in obtaining and disseminating scientific information regarding the mining and consumption of coal, and the results of the work have been of great value to technical engineers who are able to use and apply it. It is evident that we now require an extension of the idea of education, but in such form as directly to affect the men who run the boiler plants of our country, for in their hands is the saving or wasting of one-fourth of our fuel supply.

Six hundred million tons of coal were mined in the United States in 1916. If we assume only one-half of this to have been used for our industrial boiler plants, then a quarter of the coal used under boilers amounts to 75,000,000 tons per year. It is worth while to save this fuel by preventing its waste. This quantity of coal represents the use of 1,500,000 fifty-ton freight cars.

PLOTTING BLOWER-TEST CURVES

By A. H. ANDERSON, CHICAGO, ILL.

Member of the Society

To the several methods of plotting blower-test curves another method is here added, whose utility is demonstrated by the solution of problems from graphically recorded test data. Diagrams are given for impellers with blades tilted forward, with blades radial, and with blades tilted backward, the coordinates used being revolutions per minute and static pressure in inches of water. Two series of curves are given, one showing various rates of discharge in cubic feet per second, and the other the volumes discharged per second per horsepower.

SEVERAL ingenious methods of graphically representing centrifugal-fan characteristics are in use, and to these the writer adds another method which, to the best of his knowledge, is new.

To obtain the experimental data the fan is tested at several speeds, the discharge being varied by the use of different sized orifices. Figs. 1, 2 and 3 show the curves for three fans which differ only in the angle of inclination of the blades, the coördinates being static pressure and speed. The curves connect points of equal capacity, and also equal cubic feet per second per horsepower. The use of the charts is best illustrated by the six problems which follow.

PROBLEM 1. Required the input horsepower in Fig. 1 for 1360 r.p.m. and 2.7 in. static pressure.

Solution: The chart shows the fan is delivering 14.5 cu. ft. per sec. per horsepower, with a capacity of 45 cu. ft. per sec. The input horsepower, therefore, is $45/14.5 = 3.1$.

PROBLEM 2. Required the mechanical efficiency in Fig. 1 at 1360 r.p.m. and various static pressures.

Solution: (1) Cubic feet per second: read direct. (2) Velocity pressure: find in Table 1. (3) Dynamic or total pressure: add static and velocity pressure. (4) Output horsepower: take product of cubic feet per second, dynamic pressure, and a constant depending upon temperature and pressure (for usual conditions constant = 0.0093). (5) Input horsepower: divide cubic feet per second by cubic feet per second per horsepower. (6) Mechanical efficiency: divide output horsepower by input horsepower. These successive steps are

For presentation at the Annual Meeting of the AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 4 to 7, 1917. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

tabulated below. Note that the zone of maximum efficiency is found at the concave part of the series of curves.

39	0.294	47	0.425	55	0.585	63	0.760
40	0.310	48	0.445	56	0.605	64	0.790
41	0.325	49	0.463	57	0.628	65	0.810
42	0.340	50	0.483	58	0.650	..	.....
43	0.357	51	0.500	59	0.670	..	.....

Note that the zone of maximum efficiency is found along the 40-cu.-ft.-per-sec. line.

Problem 4. Required the mechanical efficiency in Fig. 3 at 1400 r.p.m. and various static pressures.

Solution: See method used in Problem 2 and the following tabulation.

Static pressure, in. water	(1) Cu. ft. per sec.	(2) Velocity pressure, in. water	(3) Total pressure, in. water	(4) Output hp.	(5) Input hp.	(6) Mech. efficiency, %
1.6	30	0.17	1.77	0.54	1.58	34.0
1.2	40	0.31	1.51	0.61	1.82	33.5
0.8	48	0.44	1.24	0.61	2.08	29.3

Problem 5. Required the r.p.m. and static pressure to change from 1320 r.p.m. and 50 cu. ft. per sec. to 55 cu. ft. per sec. (Fig. 1).

Solution: Follow the 1320-r.p.m. line down to 50 cu. ft. per sec., where the static pressure is found to be 2.29 in. The new static pressure will then be

$$2.29 \times \frac{(55)^2}{(50)^2} = 2.77 \text{ in.}$$

The r.p.m. corresponding to a static pressure of 2.77 in. and 55 cu. ft. per sec. is 1450.

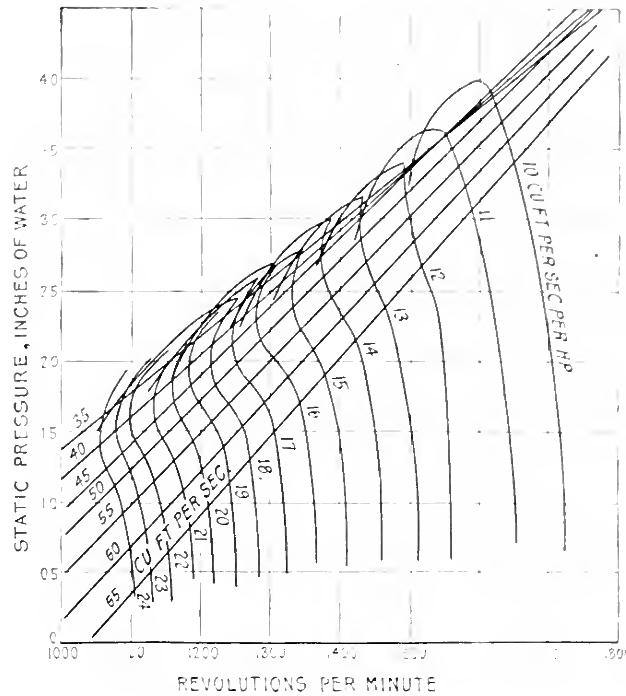

Fig. 1 Characteristic Curves, Blades Tilted Forward

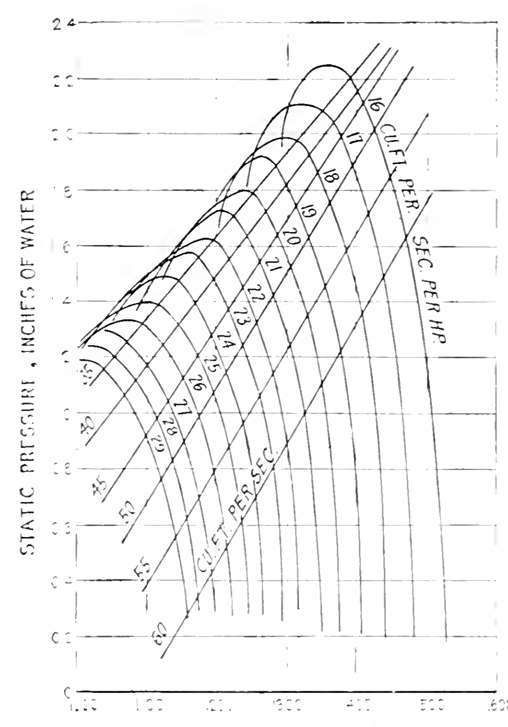

Fig. 2 Characteristic Curves, Blades Radial

Problem 6. The speed of a fan (Fig. 2) is changed from 1160 r.p.m. to 1500 r.p.m. The original static pressure is 1 in. Increase the capacity in the ratio of the speeds, 1500/1160 =

1.3, and determine ratio of new input horsepower to original, and ratio of new static pressure to original.

Solution: The capacity at 1 in. and 1160 r.p.m. is 48 cu. ft. per sec., therefore the new capacity will be $48 \times 1.3 = 62$ cu. ft. per sec. At 1500 r.p.m. and 62 cu. ft. per sec. the static pressure is 1.6 and the ratio is $1.6/1 = 1.6$, or approximately the square of 1.3. The horsepower at 1 in. and 1160 r.p.m. is $48/26.5 = 1.8$, and the horsepower at 1.6 in. and 1500 r.p.m. is $62/15 = 4$, the ratio being $4/1.8 = 2.2$, which is the cube of 1.3. Hence, when the capacity of a fan varies directly with the r.p.m., the static pressure varies directly with the square of the r.p.m., and the horsepower directly with the cube of the r.p.m.

The general arrangement of the apparatus for obtaining the power input is shown in Fig. 4. The fan was directly driven by a Sprague electric dynamometer, and the torque was meas-

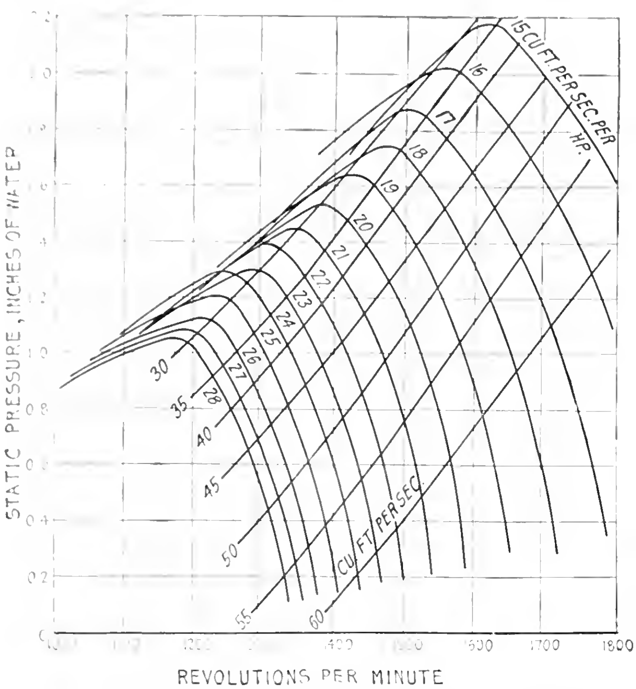

Fig. 3 Characteristic Curves, Blades Tilted Backward

ured by a Kron springless scale. The output apparatus is shown in Fig. 5. Dynamic pressures were obtained by a pitot tube and static pressures by a piezometer ring with four openings through the wall of the pipe. Fig. 6 shows the connections from the pitot tube and piezometer to the differential gages. This view shows also the method of securing the orifice plate to the discharge pipes.

Walter Humphreys, registrar of the Massachusetts Institute of Technology, has compiled registration statistics which indicate the effects of the war on technical education. The total registration is between eight-five and ninety per cent of what it was last year at the same time. The freshman year shows an increase, the percentage in terms of last year's figure being 104, while the second, third and fourth years' classes are, respectively, 93 per cent, 75 per cent and 86 per cent of the number in the school in June.

The graduate students stand at 60 per cent of last year's figure. There is the most shrinkage in the juniors, the sophomores of last year, to whom two years more of schooling has perhaps seemed a long time. The return of eighty-six per cent of the juniors to be seniors is evidence in favor of the junior summer camp. The purpose of this was to give some military

practice and an opportunity to anticipate fourth-year studies, and complete work at an earlier date.

THE MOISTURE CONTENT OF TEXTILES AND SOME OF ITS EFFECTS

By WILLIAM D. HARTSHORNE, METHUEN, MASS.

Member of the Society

THE smoothness and evenness of a thread are dependent upon the relation of its moisture content to the surrounding atmosphere at the time of spinning; and many of the hitherto puzzling defects in a finished fabric are explainable, and the remedy or method of prevention rendered obvious, as soon as the correct relationship of these facts to weaving and fabric-finishing conditions is apprehended. Moreover, the effects of moisture content upon strength and elasticity are not less important, both in manufacturing processes and commercial use.

The most significant effects of moisture content upon textiles may be classified under three general heads:

I Weight
II Dimensions
III Strength and Elasticity

Under these respective heads, among the different textile materials there is great diversity of effect, and as a consequence a great divergency in unverified opinion. The most obvious of these effects is weight, and to this factor the present paper is mainly devoted.

To conditions causing changes in weight much more effective study has been given than to those causing changes in dimensions or strength and elasticity. These latter are complicated by other factors, such as twist or weave, which tend to increase or diminish the ordinary effects of moisture.

EFFECT OF MOISTURE CONTENT ON WEIGHT

In measuring weight, long before any exact causal relationship had been established between the various factors, certain standards of moisture content for the principal textile materials, such as silk, wool, cotton and flax, and their manufactured products, had been established by custom, and to some extent sanctioned by law, in the principal Continental markets and in England, as a basis for purchase and sale.

Variations in weight between different materials due to their individual hygroscopic properties as affected by atmospheric changes alone were thus recognized, and a standard basis for figuring the standard allowances agreed upon was also adopted and with few exceptions has been steadily adhered to. This standard basis was obtained by determining the average loss in moisture of a series of representative samples, from the lot of material in question, by drying them in a proper oven at a temperature of 221 to 230 deg. fahr. until they ceased to lose weight, or the rate of loss had reached a prescribed minimum.

The standard allowances made upon this "standard" dry basis of weight (sometimes called the bone-dry or the absolutely dry basis) are commercially called "regains," a nomenclature liable to misconception and misapplication which it is important at the outset to avoid both in practical use and theoretical study. The hygroscopic capacity and other properties of both wool and cotton, for instance, are well known to be materially affected both by the temperature at which they are dried and the length of exposure to a drying and oxidizing atmosphere.

With materials as valuable as silk, wool and cotton and such of their products as are sold by weight, the actual weighing of the water they may happen to contain at the time of sale is of evident importance to both buyer and seller, when it is once understood what slight changes of circumstances can cause a loss or gain in weight involving thousands of dollars in many everyday transactions.

The standard condition upon which worsted yarn and tops combed without oil have long been bought and sold in England and on the Continent allows 18¼ per cent regain or added weight to the standard dry-weight condition. The standard for silk is 11 per cent and for cotton is 8½ per cent. Until recently no standards except for silk, which is the same the world over, had been generally recognized in the United States.

Theoretically, it makes no difference whether the standard condition of regain be assumed at one figure or another provided that the actual condition is known and that some standard has been agreed upon between buyer and seller. Practically, however, it is desirable that the standard condition be somewhere near the average expected for the country in which the transaction takes place, and that at the time of delivery the material shall in its whole mass be as near as may be in this standard condition.

CORROBORATION OF 15 PER CENT REGAIN FOR WORSTED

The importation of worsted yarns and tops into this country under foreign exporting conditions, owing to the loss of weight sustained upon storage here, had given the impression that there must be at least 2 or 3 per cent difference in weight due to climatic reasons.

It was important, therefore, in developing the new American industry of combing tops for the trade to adopt a standard believed to be safe for this country. This was put at the arbitrary figure of 15 per cent regain, an amount easy to calculate and also within expected limits. It seemed best, however, to determine with some degree of certainty how near this figure was to the average natural condition corresponding to some one locality, such as Lawrence, Mass.

With this object in view, a skein of worsted yarn, 2 42 Australian, combed in oil and spun on the Bradford system, was prepared whose absolute or rather "standard" dry weight was carefully determined by weighing and testing other skeins of the same material under exactly like conditions. This method of using substitute skeins was adopted to avoid the known effects of heat in changing the hygroscopic property of wool and other fibers.

Table 1 shows the variations in weight of this skein, which were remarkable, ranging from a little over 7 per cent to as high as 35 per cent on the calculated dry weight. There were occasional variations of 15 or even 19 per cent in 24 hours.

For presentation at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 4 to 7, 1917. The paper is here printed in abstract form and advance copies of the complete paper may be obtained gratis on application. All papers are subject to revision.

The observations recorded in Table 1 gave for outdoor conditions a general average for the year of 17.45 per cent, or something less than the standard allowed abroad; and without attempting at the time to go further into the law of change, it was felt that at least it was demonstrated that a standard of 18 per cent regain for worsted, as had already been assumed, was conservative for this country.

RELATION BETWEEN HUMIDITY, TEMPERATURE AND REGAIN

The determination of the exact relation between the three factors, humidity, temperature and regain, was a problem which the author had had under investigation for some time

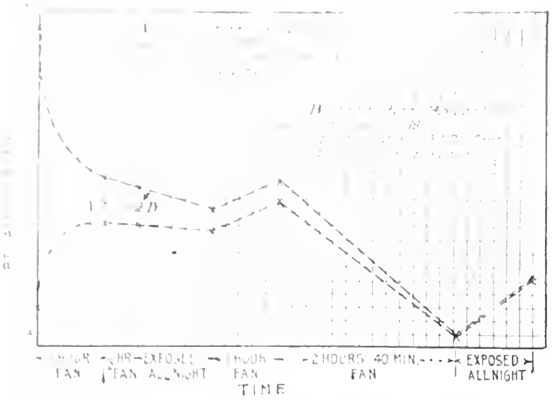

FIG. 1 LAGGING EFFECT IN SKEIN TAKING UP OR PARTING WITH MOISTURE

prior to 1905. That the absorption of moisture by worsted yarn was in some manner dependent upon relative humidity and temperature was abundantly shown by the year of exterior observations recorded, and also by many interior records made subsequently. It seemed possibly true that the atmospheric pressure affected the result, but its effect was so far overshadowed by the element of temperature that, for practical mill purposes, it was evident that the height of the barometer could be neglected. In fact, all observations for either relative humidity or skein regain were made on the assumption of 30 in. barometric pressure.

*TABLE 1 VARIATIONS IN WEIGHT OF SKEIN OF WORSTED FOR ONE YEAR

	Lowest Day		Highest Day		Lowest Observation		Highest Observation		Greatest Difference in 24 Hours	
	Per Cent	Date	Per Cent	Date	Per Cent	Date	Per Cent		Per Cent	Date
May	11^{60}	17	21^{50}	27	9^{7}	17	22^{1}	6 and 27	8^{2}	6 to 7

January	[illegible]	[illegible]	[illegible]	25	[illegible]	29	34^{9}	25	15^{1}	24 to 25
February	[illegible]	[illegible]	[illegible]	6	[illegible]	25	33^{4}	6	17^{3}	6 to 7
March	[illegible]	[illegible]	[illegible]	[illegible]	10^{2}	27	28^{3}	20	16^{4}	30 to 31
April	[illegible]	[illegible]	[illegible]	2	7^{3}	30	24^{0}	2	12^{2}	1 to 2

General average (by months) for the year, 17^{45} per cent.
Lowest average periods (April), 14^{15}, and (May), 14^{86} per cent.
Highest average periods (November), 22^{02}, and (December), 19^{28} per cent.
Lowest observation (April 30), 7^{3} per cent.
Highest observation (November 26), 35^{1} per cent.

The first efforts toward the solution of the problem of finding the relation were directed to obtaining in a closed room, for as long a period as possible, a uniform state of moisture and temperature. The difficulty of maintaining both these factors uniform for a sufficient length of time to determine more than a very limited range of facts was found to be extremely great, if not impossible, with apparatus then available. So far as these facts were determined, they indicated that the same skein of worsted yarn can always be relied upon to reach the same weight under like conditions, if given sufficient time.

For the purpose of eliminating the effect of hard twist in retarding the absorption of moisture and the effect of oil upon the net result, a quantity of 2/24 soft twist, French spun, fine Australian yarn was prepared and extracted with ether, dried, and extracted again with warm water to which a few drops of ammonia had been added. After allowing it to hang up for some time to come to its natural state, this yarn was made up into groups of skeins of equal lengths and approximately equal weights. The final weight and moisture state of the groups was carefully determined after they had been hung up together again for about two days, by drying out individual skeins of the different groups in the ordinary ventilated Bradford oven at a temperature of from 220 to 230 deg. fahr., until they ceased to lose weight, and also by leaving small two-gram

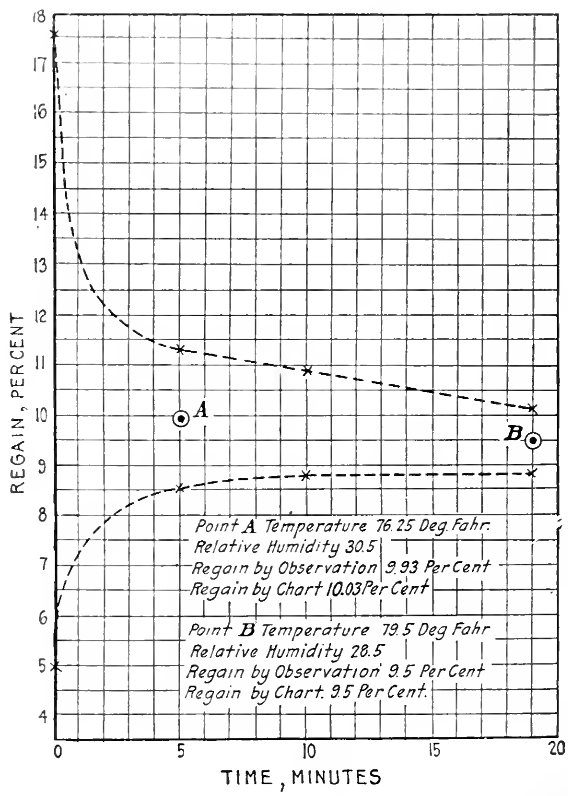

FIG. 2 LAGGING EFFECT IN SKEIN TAKING UP OR PARTING WITH MOISTURE

skeins in weighing bottles under a dessicator containing strong sulphuric acid.

These two methods were used to check each other from time to time during the experiments, to establish the true weight of the skeins being used as moisture indicators.

Attention has already been called to what has been termed the "lagging effect," due to the time required by a skein of yarn to take up or part with moisture. The effect of this is

to show for a given humidity and given temperature a higher result when the skein regain condition has been a falling one, and a lower result when that condition has been a rising one. In undertaking, therefore, a careful series of experiments, it was deemed necessary to make the skeins to be examined of such a size that they could be accurately weighed on a delicate balance, and not be so large that the amount of moisture which might be absorbed or parted with by a given skein would require a great many cubic feet of air to supply or displace it.

Upon comparing the results obtained from two skeins hung together, one of which had been previously exposed to a damp atmosphere, and the other to a comparatively dry atmosphere, it was soon found that while it might require hours or even days to bring the skeins exactly together again, the mean between the two at any time after 15 or 20 min. was practically the same in repeated experiments for the same temperature and relative humidity, and presumptively equal to what a third skein would have shown which had been a long time exposed to identical conditions. It was therefore assumed that this mean could be relied upon to quickly determine the true regain relationship for any not too rapidly changing conditions. It was thus possible to make use of the very lag effect, which had previously rendered individual observations seemingly incompatible, to establish comparatively accurate and true results. Figs. 1 and 2 are intended to illustrate this lagging-behind and coming-together effect and the method of obtaining quick results.

In order to compare the results obtained by this method, a special form of charting was devised, shown in Fig. 3 for worsted and Fig. 4 for cotton, on a scale greatly reduced from the original, where the ordinates represent regain and the abcissæ moisture per cubic foot of space, for the temperatures and relative humidities found and shown in the figures. It will be observed that the lines joining points of the same relative humidity (for example, the 50 per cent line) cross the isothermal lines in a general oblique direction, curved slightly

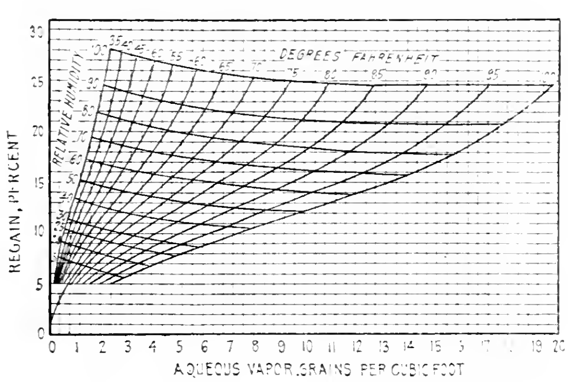

FIG. 3 ISOTHERMAL AND RELATIVE-HUMIDITY LINES FOR WORSTED

convex, on the downward side; that is to say, for a given relative humidity the regain is less at the higher temperature, but not less in a constant ratio.

By the aid of this charting principle, a sufficient number of points were located to trace the isothermal and the relative humidity lines shown, and from these charted results it was found possible to tabulate by interpolation the percentage regain on worsted with a fair degree of accuracy for each percentage of relative humidity from 15 per cent up to near saturation, and for isothermals 5 deg. of temperature apart from 35 deg. fahr. to 100 deg. fahr.

The data for securing the cotton chart were by no means so complete as those used for the worsted chart, and therefore the same degree of accuracy was not expected for it.

It will be seen from Figs. 3 and 4 that the regains for cotton are approximately one-half of those for worsted under like conditions, but the relative-humidity lines are more nearly straight and therefore bear a more nearly constant ratio to the regains.

Another method of comparing results is shown in Fig. 5, in which curves of saturation (100 per cent humidity), 60 per

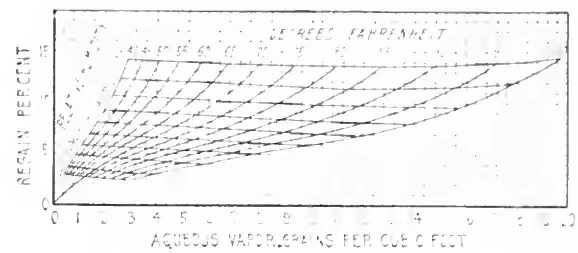

FIG. 4 ISOTHERMAL AND RELATIVE-HUMIDITY LINES FOR COTTON

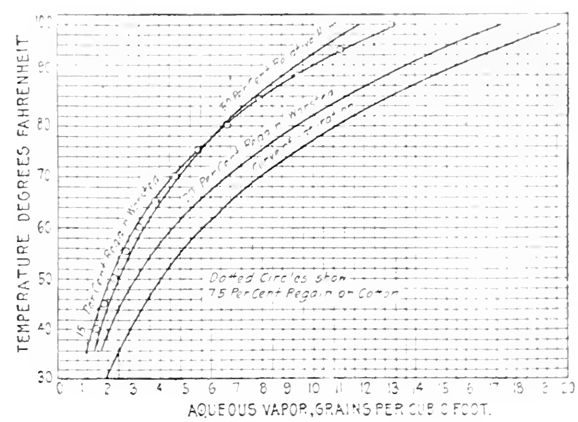

FIG. 5 REGAIN OF COTTON AND WORSTED

cent relative humidity, 15 per cent regain in worsted, and (to avoid confusion) a number of points only on the curve of 7½ per cent regain in cotton, are represented. An additional regain curve for 20 per cent on worsted is also shown.

It will be noticed that at ordinary mill temperatures the 7½ per cent curve for the cotton here used closely coincides with the 15 per cent worsted curve, and within the limits of observation their deviation is not great at either high or low temperatures. In the absence of other considerations, this fact might be taken therefore as reason sufficient for establishing a 7½ per cent regain for cotton for this country, if it be conceded that 15 per cent is the proper standard for worsted.

It is interesting to note also that the 60 per cent humidity curve, Fig. 5, crosses the combined regain curve, just named, at about 77 deg. fahr., a room condition which, according to Sconfietti, is compatible with both good work and comfort in a cotton-spinning room.

Sconfietti gives his own experience, as corroborating that of other men, that the most favorable temperature for manufacturing cotton (and textile fibers in general?) is between 68 and 77 deg. fahr., while the relative humidity for cotton should be:

In carding, between 50 and 55 per cent
In spinning, between 55 and 60 per cent
In weaving, between 65 and 70 per cent.

These figures would indicate a regain condition for cotton, by the 1911 tables:

In carding, from about 6.5 per cent to 7.2 per cent
In spinning, from about 7.2 per cent to 8.0 per cent
In weaving, from about 8.6 per cent to 9.5 per cent.

or, in other words, for cotton the stock should be *gaining* at each step of manufacture.

Whether this be true or not for cotton, it is not true for worsted so far as the Bradford system of spinning is concerned. For the Bradford system of worsted spinning, even though the stock contains oil, there seems to be no doubt that it must be losing moisture during the process of spinning to make a good spin, hence the necessity, if the top contains only 15 per cent regain, for keeping the moisture condition well up during the processes of drawing and roving or else for long aging in a cool, damp cellar before going to the spinning frame. The latter plan used to be thought an absolute necessity, but modern successes in humidification have very largely obviated it.

One of Schloesing's methods involved the use of pure sul-

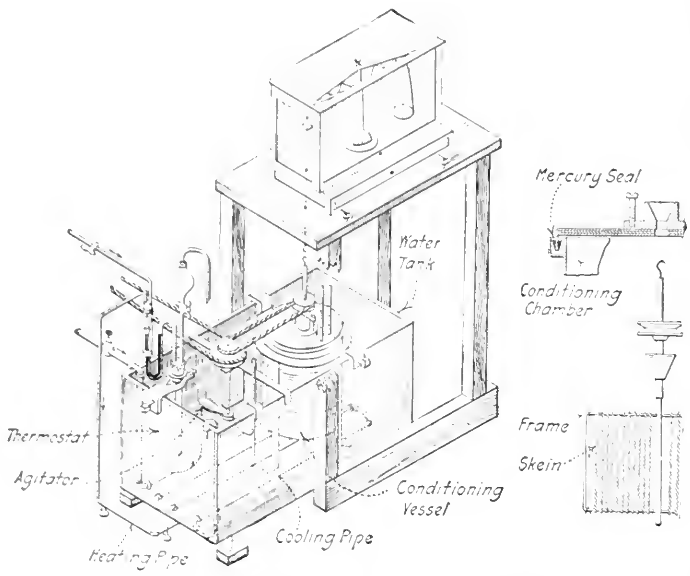

FIG. 6 APPARATUS FOR DETERMINING REGAIN

phuric acid of known strengths in obtaining known and comparatively constant states of relative humidity in a closed vessel or chamber.

Both of his methods, though checking up well with each other, involved the question of control and length of time required to arrive at results—a time so great that to apply them over a wide range of temperatures to make a complete comparison with the writer's figures seemed out of the question. The sulphuric-acid method was the simplest but, though making use of conditions of known humidity in obtaining the facts (not the law) of regain, neglected the phenomenon of lag—one of the time elements in the problem.

To accomplish this, it was necessary to obtain the elimination of the lagging effect by direct observations under conditions of constant temperature and constant humidity [illegible] maintained, or so closely known that the constant [illegible] could be calculated. In attempting this, [illegible] Schloesing's sulphuric-acid method in an apparatus developed after much experimenting, shown in Fig. 6, so that observations could be repeated over and over again under conditions calculably alike upon the same and upon different pairs of skeins to obtain a satisfactory average for a given kind of material at as many points of temperature and humidity as desired.

The principle of operation of the apparatus is: A pair of skeins, one moister and the other drier than the proposed humdity would give, are hung on the two ends of a specially designed metal frame within an enclosed metallic vessel, the cover of which is sealed by mercury. Excepting the top, this vessel is entirely surrounded by water, the temperature of which can be kept constant by a thermostat. In the bottom of this chamber, paraffined for protection, varying known strengths of sulphuric acid are placed and the framework revolved in the air above by a small motor, which also turns an agitator in the outside water. Thermometers pass through the lid of the sealed chamber, one terminating in the air and the other in the liquid below, so that the exact temperature of each is known and therefore the exact equilibrium conditions are calculable. The bearing for the shaft is a copper tube held in a conical plug, making a practically air-tight joint. When it is desired to weigh the combination, the driving band is disengaged, and the hook from the scale above inserted in the hook of the shaft of the framework, just lifting it from its conical bearing, so that the weight can be taken accurately.

It will be noted that: *The original dry weights of the skeins having by calculation, from blank tests on other skeins, been made equal, one-half of the sum of the weights found always represents the average present condition of the skins.*

It was soon found that in about an hour's time an equilibrium was established between the two skeins so that there was neither gain nor loss thereafter, while the temperature remained the same.

It was, however, found on repeating the same experiment on the same pair of skeins, in the same order, that is, the same skein always remaining the drier, that the successive observations gave continually lower results for the average regain; but if the skeins for a repeated experiment were alternated in the exposing condition, that is, if the one which had been drier in the first instance was made the damper in the second, then the results represented a very nearly constant condition of regain, not only for the same pair of skeins, but for duplicate pairs, and in the final accepted results a series of tests on duplicate samples, alternating for the moist and dry state in each, were averaged for each point of regain determined.

By suitable humidities and temperatures, thus predetermined and accurately controlled, points of regain in sufficient number were found not only to confirm the basis for the general law previously propounded in 1905, but to extend its application so as to cover for both worsted and cotton the relationship of humidity and regain at all temperatures within the limits of the apparatus as arranged, giving reliable results not previously found possible.

Having obtained these accurate comparative points, the mathematical considerations as first announced in 1905 and their further application to the more complete conception of the laws of regain as developed in 1911 may be briefly summarized.

SUMMARY OF THE LAWS OF REGAIN

To summarize these laws of regain in cotton and worsted, we can say:

First. The general law for cotton and worsted, and probably for any other textile fiber, may be expressed by the formula

$$K\ R\ T^3 = H \times 5771.44 \times 10^8$$

in which H represents any given relative humidity expressed

decimally; R the regain at any absolute temperature T: K is a variable coefficient depending upon H, R and T in such a way that for $H = 1$ the product of $K\ R\ T^3$ is a constant quantity represented by the number 5771.44×10^6. In this, 5771.44 is the weight in grains of a cubic foot of aqueous vapor at any temperature multiplied by the corresponding absolute temperature in degrees fahrenheit, divided by the maximum elastic force of aqueous vapor at that temperature, expressed in inches of mercury. In this expression, therefore, we are independent of tables for saturated aqueous vapor, either for unit of weight or elastic force.

Second. For any given temperature the relation of values of R to the variable K, for both worsted and cotton, is expressed by a hyperbolic equation, differing for each substance.

Third. For any other temperatures the law for worsted is: *For the same humidity the squares of the regains at different temperatures are to each other inversely as the cubes of the corresponding absolute temperatures.*

Fourth. The law for cotton is: *For the same humidity the first powers of the regains at different temperatures are to each other inversely as the first powers of the corresponding absolute temperatures.*

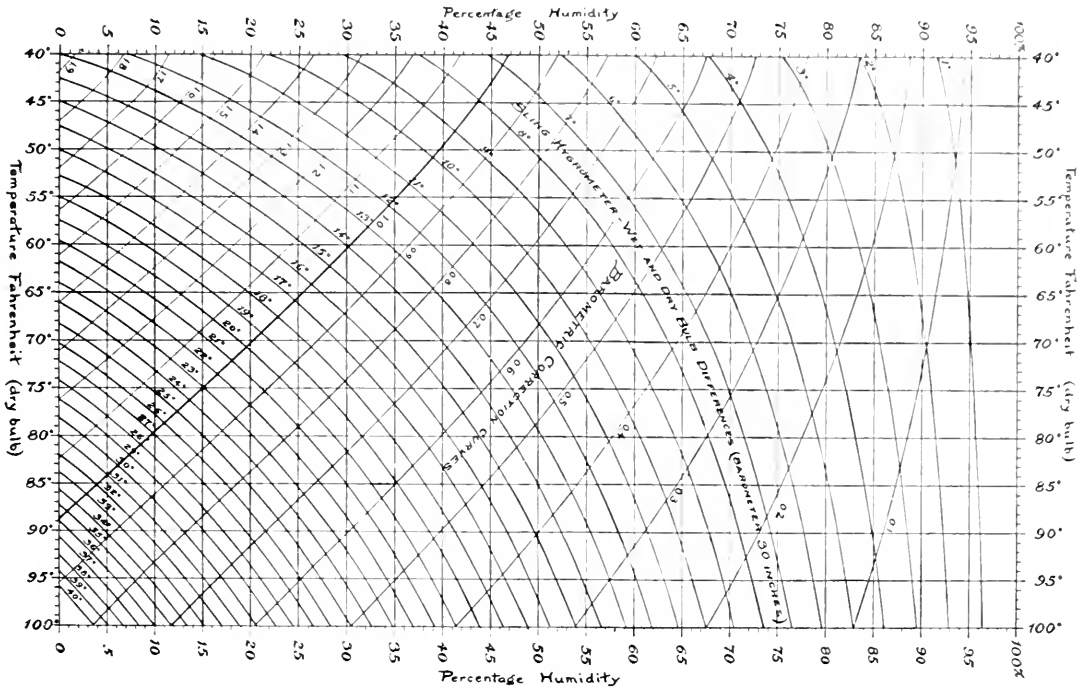

Fig. 7 Barometric-Correction Chart

Note.—Figs 7 to 11, inclusive, are reproduced from the author's original drawings to ensure their accuracy.

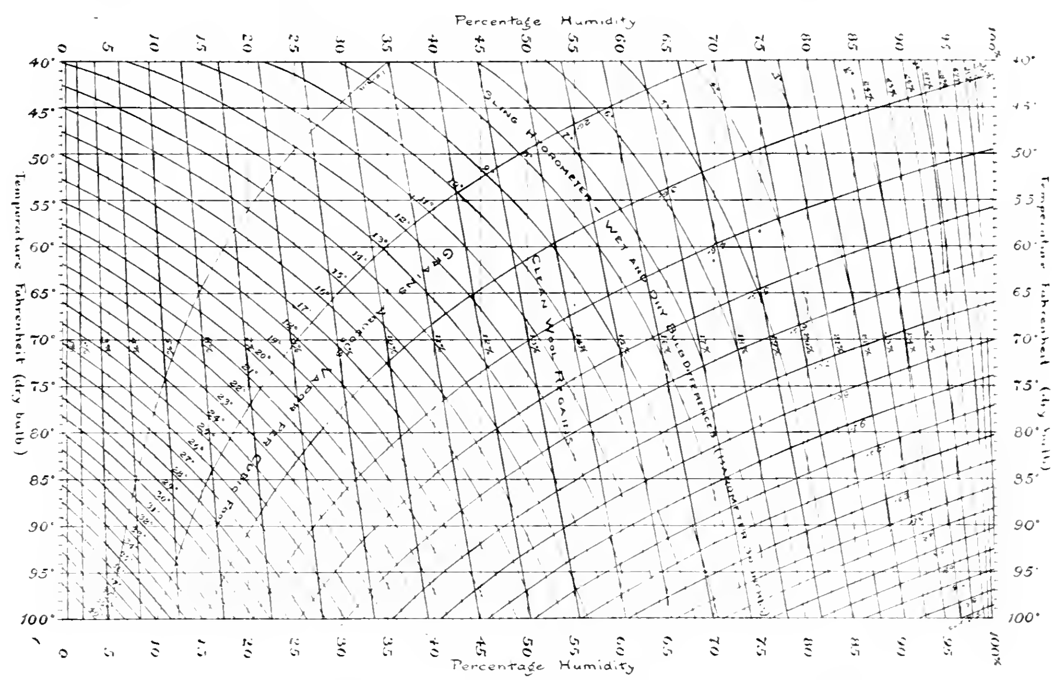

Fig. 8 Absolute- and Relative-Humidity Chart. Wool

No other substances have as yet been compared in this manner by the writer, but for such substances it is quite possible that all these relations, except those of the general formula, may be decidedly different.

points of their construction, nor are they adaptable for everyday use. By properly constructed charts on a unit-system basis, it is possible to avoid the necessity for using any tables in either hygrometric observations as such, or the reading of

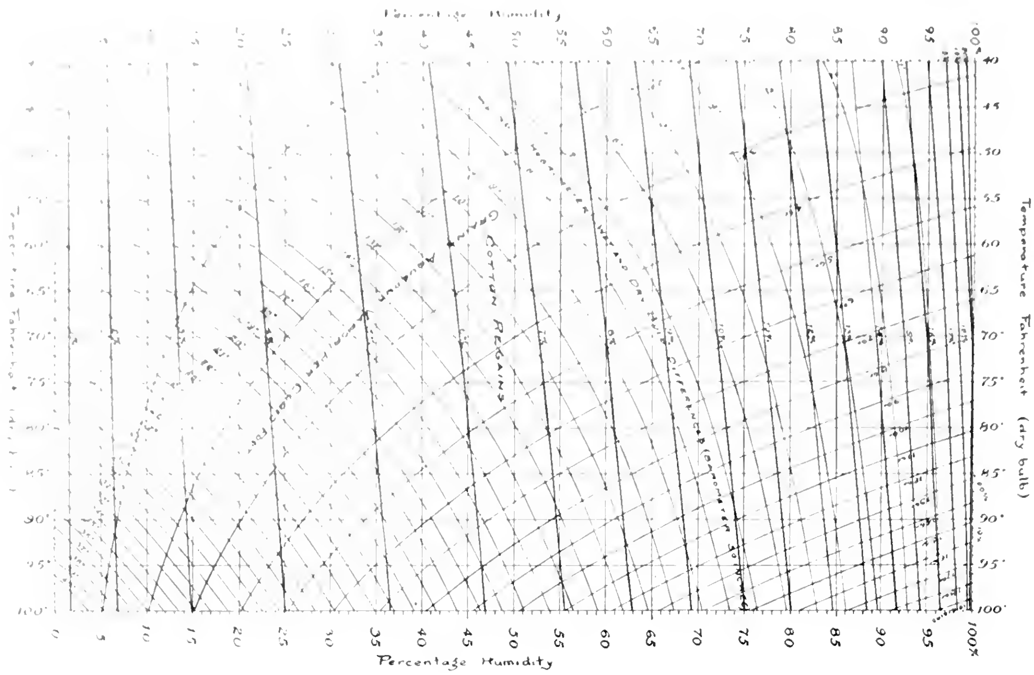

FIG. 9 ABSOLUTE- AND RELATIVE-HUMIDITY CHART, COTTON

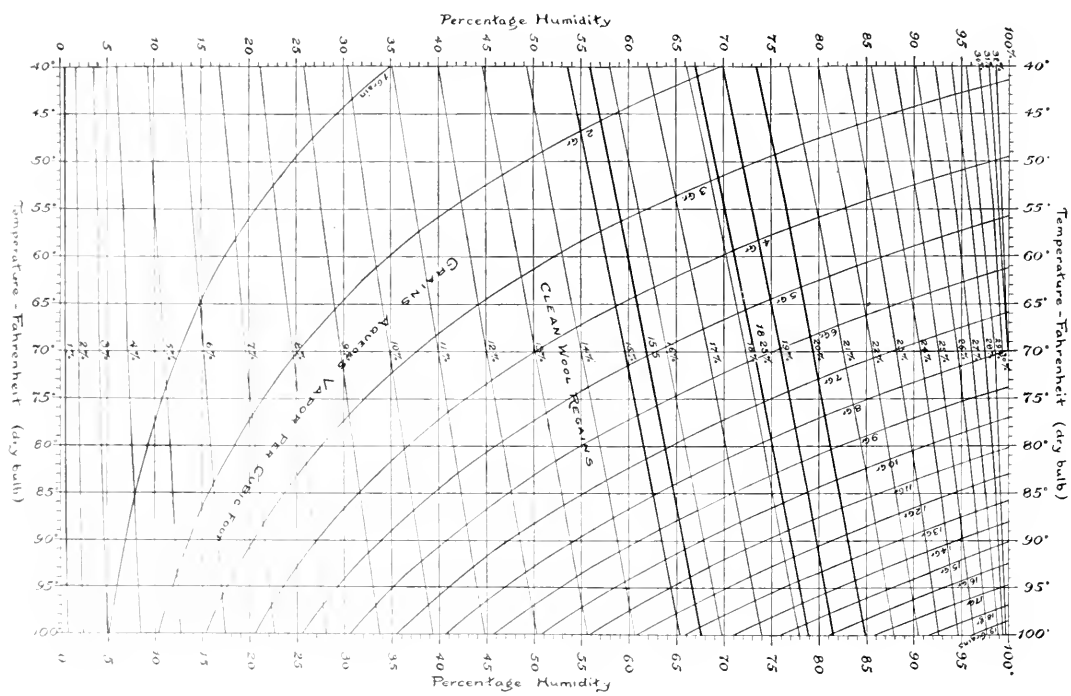

FIG. 10 UNIT-VARIATION REGAIN LINES, WOOL

ANOTHER METHOD OF CHARTING AND FURTHER DEDUCTIONS EXPLAINED

Though graphically expressing the relations and laws referred to, the charts so far shown do not lend themselves readily to accurate portrayal of the established facts at all the corresponding conditions of equilibrium therewith for the several textile materials.

Figs. 7 to 11 were devised for this purpose, so far as commercial and mill uses require, for wool and cotton. On each of them the vertical lines represent (as labeled) 5-deg. inter-

vals of temperature and the horizontal lines 5 per cent intervals in relative humidity. For closer reading, each degree and each per cent are marked off respectively at the top and bottom and on both sides of the charts.

Barometric Corrections. Fig. 7 is needed in ordinary mill use only in a negative sense. It shows the effect of the height of the barometer, by unit variations, in obtaining the correct relative humidity from readings of the sling hygrometer, and can be read as closely as necessary for practical purposes. On respect to the absolute- and relative-humidity lines in whatever manner either may have been determined.

On each of these four figures, the unit-regain curves are nearly straight lines for both clean wool and cotton, running in a general upward direction from left to right, and labeled from 1 to 32 per cent on the wool charts, and from 1 to 20 per cent on the cotton charts.

In Figs. 10 and 11, besides the unit-difference curves, there are three extra lines, two in Fig. 10 and one in Fig. 11,

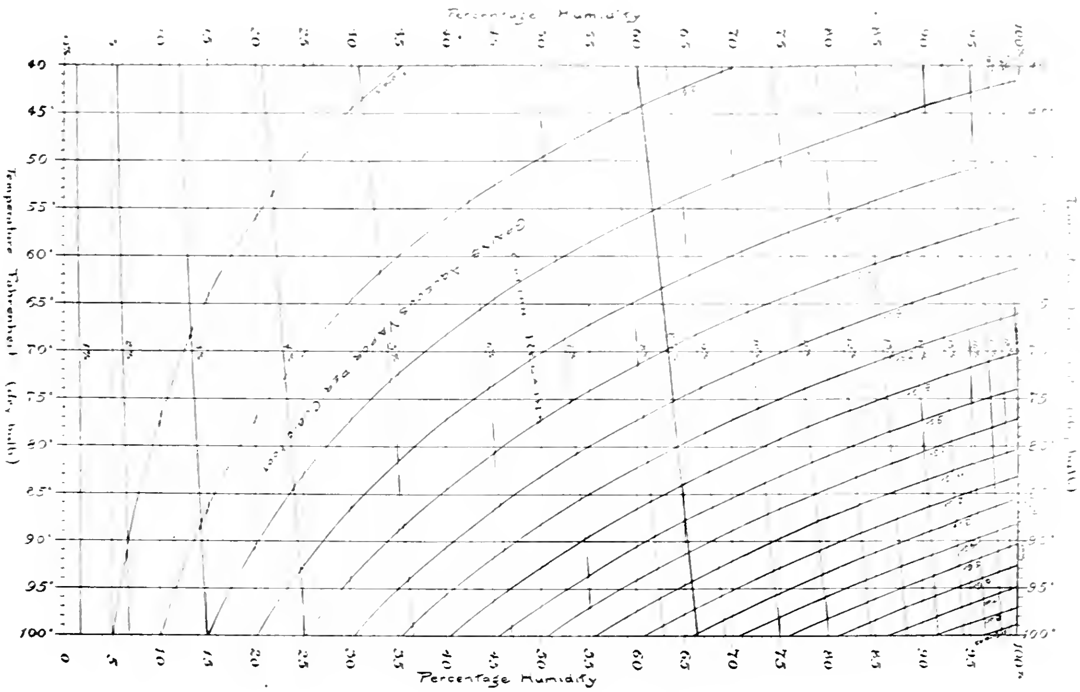

Fig. 11 Unit-Variation Regain Lines, Cotton

it and on Figs. 8 and 9 the curves running in a convex upward direction from left to right and labeled from 1 to 40 deg. downward represent the position of unit differences in the wet-and-dry bulb readings of a sling hygrometer and are plotted from relative humidities, with barometer at 30 in., very carefully calculated to the nearest one-tenth of 1 per cent.

The lines crossing these wet-and-dry-bulb difference curves and running from left to right, concave downward, are designated barometric-correction curves. They are labeled, beginning at the lower left-hand corner, 1.9, 1.8, 1.7, etc., to 1.0, and then continuing 0.9, 0.8, etc. Their significance is this: The correction in per cent to be added to or subtracted from the humidity findings by the chart curves will be one times the drop of the barometer in inches below 30, and one times the rise above 30, respectively, on every reading falling on the line labeled 1.0, and 0.9 times, 0.5 times or 1.1, etc., times such readings falling on the curves so labeled.

For readings *falling between* these lines, a relative estimate can be interpolated by inspection, if need be.

Regain Curves. Figs. 8 and 9 are intended to be used in determining from sling-hygrometer readings both absolute and relative humidities, within the limits of temperature indicated and the corresponding regains, for a state of equilibrium therewith on wool and cotton respectively.

Figs. 10 and 11 show within the same limits of temperature the unit-variation regain lines for wool and cotton with labeled, respectively, 15.5 per cent, 18.25 per cent and 8.5 per cent. These, with the three emphasized lines at 15, 19 and 20 per cent, represent equilibrium conditions for certain commercial standards in wool and cotton, to be more fully described and explained later.

All these lines are plotted from data developed either directly from the writer's original formulæ, or, where admissible, by interpolation from the tables in the Appendix.

Absolute-Humidity Curves. In each of Figs. 8 to 10 are plotted curves running from left to right in a convex direction downward, labeled, respectively, 1 grain, 2 grains, 3 grains, etc., up to 19 grains, which represent weights of aqueous vapor per cubic foot under the temperature and relative humidity conditions indicated at their points of intersection with the temperature and humidity lines. These curves are plotted from data calculated from Professor Marvin's Table 12 in U. S. Weather Bureau Report No. 236.

ILLUSTRATIONS OF THE PRACTICAL USE OF THE CHARTS

Example 1. Assuming a 30-in. barometer, suppose an observation by the sling hygrometer gave a dry-bulb temperature of 65 and wet-bulb 60 deg. Note in Fig. 8 that the 5-deg. difference curve crosses the vertical 65-deg. temperature line just a little below its intersection with the horizontal 75 per cent humidity line; that the curve for 5 grains of aqueous vapor per cu. ft. crosses a little to the left of, and the 19 per

cent regain for clean wool exactly at the same 75 per cent point. The results would be properly recorded:

Temperature, deg.	65
Relative humidity, per cent	75
Absolute humidity, gr. per cu. ft.	5.1
Wool regain, per cent	19
Cotton regain, per cent	10.7 (Fig. 9)

It will be observed that even on the reduced scale of Fig. 9 it would be possible to read the relative humidity closer and call it 74.8 per cent, and the other items correspondingly less; but it would not be worth while to do so for a single observation, because that degree of accuracy would rest upon the assumption that the difference in the wet- and dry-bulb temperature had been taken with an observation error of less than one tenth of a degree—an improbable supposition, except with a very careful observer using very refined instruments. Mill observations are usually taken to the nearest ½ deg., implying a possible error of over 0.2 deg., or as much as 1 per cent in any single record of humidity, under approximately like conditions.

Again, under like circumstances, referring to Fig. 7, it will be seen that the observed point falls approximately on the barometric-correction curve 0.3, which means that it would require a difference of 3 1/3 in. in the barometer, more or less than 30, to make a difference of 1 per cent in the humidity reading; or, in other words, an amount no greater than the possible error of an ordinary mill observation.

Example 2. For dry bulb 77½, wet bulb 61 deg., difference 16½ deg., the point is found at:

Temperature, deg.	77½
Relative humidity, per cent	37½
Absolute humidity, gr. per cu. ft.	3.8
Clean-wool regain, per cent	10.3 (Fig. 8)
Cotton regain, per cent	5.3 (Fig. 9)
Barometric-correction factor	0.65 (Fig. 7)

In this case, to need a correction of as much as 1 per cent in the humidity record, involving 0.2 per cent and 0.1 per cent only in the reading for the regain conditions of wool and cotton, respectively, would require [since $(1.00 \div 0.65) = 1.54$] a drop in the barometer to below 28½ in. or a rise to above 31½ in.

OTHER INTERPRETATIONS AND INFERENCES

As regards barometric corrections in mill practice, the humidity conditions usual either for warehouse storage or manufacturing rooms evidently lie above the barometric-correction curve labeled 1.0; and Figs. 8 and 9 show that it requires, for conditions in the neighborhood of this line, a difference of about 5 per cent in relative humidity for wool and 10 per cent for cotton to make as much as 1 per cent difference in their respective regain conditions. Consequently, the probable maximum effect upon humidity readings of any barometric change likely to occur in our latitude and at elevations not exceeding 1,000 ft. would only be equivalent to about one-half of one per cent in the proper reading for the regain of wool and one quarter of 1 per cent for cotton. The common custom, therefore, of paying no attention to barometer [illegible] for moisture conditions in factories [illegible] is quite justifiable from a practical standpoint.

It cannot at present be said that any definite standard for moisture regain on cotton, manufactures of cotton, raw or scoured wool, worsted yarns, or other manufactures of wool except tops, or other textile materials except silk, is properly recognized in the trade in this country.

The most important reason for not adopting the English and Continental standards for wool here lies in the fact that it is more difficult to maintain indoor atmospheric conditions in our climate corresponding to such standards, and, moreover, tops and yarns actually containing such amounts of moisture, if long stored unprotected from mildew, are likely to become seriously damaged.

In the writer's experience there is little such danger of damage at 15½ per cent on wool (15 per cent on oil stock) or 8½ per cent on cotton. While it is true that for the best conditions of spinning it is better to have in the material an amount of moisture equal to, or possibly even greater than, the Bradford standards, in order to allow for necessary losses by evaporation and still maintain a humidity condition of spinning rooms at a point where electrical action in cold weather would be without material effect, yet this can be taken care of by the spinner himself, and need not involve the danger from mildew by long storage at Bradford standards in our warmer climate. However, with material worth anywhere from 50 cents to \$2.00 per lb. or more, it is easy to see the commercial importance of knowing at what price 100 lb. of bone-dry material is being bought or sold, but it makes little difference, as a commercial transaction, whether the price be fixed on the basis of that 100 lb. weighing 110 lb., 115 lb., or even 120 lb., providing the standard is accepted, condition determined, and corrected weight billed up.

The skin which forms on the surface of some oil paints and varnishes is practically airtight. According to a paragraph in the *Zeitschrift des Vereines Deutscher Ingenieure* of July 21, 1917, such a skin, which is, at any rate, waterproof and dustproof, can be formed on sacks of jute and on bags of cardboard, etc., for the transport of lime, chalk, cement and dextine, as well as for packing greasy and oily materials. The process is described as the Plüss-Stauffer process, and it is stated that the skin is pressed upon the material, which need not be a texture, by special machinery.—*Engineering,* September 28, 1917, p. 340.

Aluminum bronzes can be improved by thermal treatment. When they contain less than 7 per cent of copper, the thermal treatment will not affect the properties much, according to the *Giesserei Zeitung* for June 1, 1917. Higher-grade bronzes can be hardened, however, and by the further addition of iron, silicon and other elements the mechanical properties of the alloys can be much varied. Thus, for instance, bronzes can be prepared having a Brinell hardness of 100 without being brittle. An aluminum bronze, resembling in its mechanical properties a 0.35 carbon Swedish steel, was given hardness values ranging from 100 up to 260 by various thermal treatments; such bronzes will answer as bearing metals even for high speeds. The following figures are given as to the properties of a 10 per cent aluminum bronze containing some titanium, the percentage of which is not stated; the figures refer to the original alloy as cast, to the quenched bronze, and to the bronze after the thermal treatment at different temperatures: Limit of elasticity in kg. per sq. cm., 9.6, 19.8, 27.7 to 19.2; tensile strength in kg. per sq. cm., 51.8, 73.6, 67.7 to 64; elongation in per cent, 19.5, 1.0, 5.5 to 1.4; contraction of area in per cent, 33.7, 0.8, 9 to 18.5; Brinell hardness, 100, 262, 158 to 140.—*Engineering,* September 21, 1917, p. 305.

LABOR-TURNOVER RECORDS AND THE LABOR PROBLEM

By RICHARD B. GREGG,[1] BOSTON, MASS.

Non-Member

The application of rational methods of analysis to the conduct of the operative details of industrial establishments has long been accepted as an effective means of approaching the maximum efficiency of output, and in recent years production problems of all kinds have been studied and solved by such methods. In this paper the author advocates the application of a similar mode of analysis to an increasingly important phase of the labor problem, namely, the labor turnover, or the shifting of workers from one place of employment to another. He considers various causes that have given rise to the problem and suggests other aspects of the subject that still remain to be explored, leaving a discussion of the remedies which have proved successful for future treatment.

THE study of labor turnover is the measurement of the movement of industrial workers in and out of their employment, and the analysis of its causes and results. The value of such study is patent to everyone who has ever handled employment. The difficulty of training a continually shifting force, the low quality and quantity of production obtainable from tramp workers, the lack of team play, low standards, poor tone, discontent and unrest in an establishment where the labor turnover is high—all these are factors that gravely affect both the annual balance and the ease and effectiveness of management.

There is, of course, a certain amount of labor turnover which is unavoidable and normal. The factory will always be losing people from old age, death not caused by industrial accident or occupational disease, marriage, changes of residence or domestic events wholly uninfluenced by the character of work or pay. What this normal amount will be will vary from factory to factory according to local conditions. A careful estimate in one instance placed it at 21 per cent of the total working force. The amount of turnover in excess of this normal, excepting lay-offs due to slackening demand for product, may be considered a kind of barometer of dissatisfaction, either of employer with employee or of employee with position. The quittings are in effect a sort of gradual continuous strike.

Let us imagine a factory where there is a high labor turnover, with all its consequent difficulties. What would it mean to apply scientific methods to this problem, and what would be the probable results? First of all, we must get the facts. How great is the labor turnover? To get this we must examine the payroll or keep a record of the hirings and quittings and discharges from the entire factory for a given period of time—say a year. By comparing the total number of "leavers" for all reasons with the total normal number of workers in the factory we may obtain the turnover in terms of precentage, which is useful for comparisons with other periods or other groups of workers. For purposes of thorough analysis it will be well to obtain the amount and percentage of turnover for each department and each position with the departments. In one factory the annual turnover for the entire concern for several successive years was in the region of 45 per cent. Again, in one department in a cotton mill the turnover last year was over 500 per cent. The turnover in some positions will occasionally run much higher than that.

Having obtained the annual turnover *in toto* and in detail in this fashion, we will get further light on the situation by working out the turnover for each week and for other divisions of the year such as each of the thirteen four-week periods. In this way we learn whether there are any seasonal or periodic fluctuations. In some industries, such as the building trades or the manufacture of clothing, such variations are very marked.

It is obvious that these measurements and analyses tend to make it more possible to learn the causes for the turnover. Once we learn real causes and definitely locate responsibilities we are in a position to begin to control the phenomenon.

Carrying out our analysis and arrangement of facts still further, we can often obtain very valuable indices of the reasons for high labor turover. For instance, grouping the leavers according to their actual earnings will show the significance of the wage factor as a cause for leaving. To illustrate how this works out: A certain cotton mill learned that there was a high labor turnover in its power department. Upon further analysis the turnover was found to be confined almost entirely to the coal handlers. Inquiry showed that these men were receiving fifty cents a week less than the coal handlers at the local railroad station. The wage was raised fifty cents, the turnover ceased, and the management was relieved of its worry about demurrage charges. Usually a large part of the shifting will be found in the low-paid groups. The results of most experiments with this fact seem to show that low wages are much more the cause of the high turnover than any inherent and unchangeable characteristics of that group of workers.

Other groupings that might prove significant are sex, nationality, age, foremen, rooms, heaviness of work, amount of illumination or ventilation of work place, dirtiness of job, method of pay, amount of accident risk, anxiety, amount of other fatigue factors, distance of workers' homes, etc.

A further aid in learning the causes for leaving is making inquiries from the leavers before they go and from the foremen.

As a result of all this recording of facts, measuring, weighing, testing, analysis and classification, we find ourselves able to determine the real causes for the turnover in a large number of cases. Sometimes the causes will be simple, as in the case of a motor company that learned that most of its leavers had resided a considerable distance away from the plant. By giving preference to applicants living nearby the turnover was grad-

[1] 75 State Street.

[illegible] greatly reduced. Usually, however, there is a complex of conditions, and the apparent cause merely serves to release discontent that has gradually been accumulating for a number of reasons. With patience and skill we can usually arrive near to the truth. By further measurement and analysis we can determine, or at least approximate, the cost of losing a worker in a particular position and training another. These costs may be roughly divided into overhead costs and operating costs.

Among the overhead costs there are:

1 More rapid depreciation of machinery because of ignorance or lack of skill of new workers
2 Extra floor space and extra machines to provide against idleness of a certain amount of machinery due to shifting labor.

Operating costs may include any or all of the following:

1 Time of increased superintendence or office work:
   - *a* Time spent by foremen or superintendent in discharging a workman where that is the way the vacancy occurred
   - *b* Time spent by foremen or other workers in training the new employee
   - *c* Time spent by clerks on additional payroll or other records.
2 Machine costs, covering
   - *a* Time machinery is idle when a new worker cannot be obtained immediately
   - *b* Idle machinery for temporary stoppages due to ignorance or lack of skill of new worker
   - *c* Repairs to machines or renewals of tools broken for the same reason.
3 Material costs, including
   - *a* Waste or damaged material due to ignorance or lack of skill of new worker
   - *b* Difficulties in subsequent processes due to poor work by new employees in previous processes
   - *c* Lower production while new employee is working up his best skill.
4 Additional accident cost due to higher rate of accidents among new employees.

These two kinds of overhead costs and four groups of operating costs, while not exhaustive, serve to illustrate the method of observation, recording, measurement and analysis which is just as helpful in this aspect of the matter as elsewhere. With knowledge so obtained the factory manager is in a position to estimate more truly the importance of this problem and to judge whether he can afford to take certain steps to reduce this turnover.

As is probably well known, those who have made the most careful studies of this question find that it costs about $10 to replace an ordinary laborer, and as much as $300, and perhaps more, to replace skilled workers. The cost varies, of course, with the nature of the position. The total losses are unquestionably enormous. Mr. Magnus Alexander in his well-known study, it may be remembered, estimated the losses in a group of twelve metal-working factories in a single year at not less than $831,000; and one textile mill, employing about two thousand workers, may be mentioned which is losing at least $20,000 annually from its high labor turnover. Other instances could be multiplied.

It should be remembered, moreover, that none of these estimates includes the losses to the employees or the community. What frequent job shifting means to the employee and his family in terms of frequent house moving, ill-feeling, discouragement, bitterness, decrease of skill, lowering of pride and self-respect, we have no means of measuring.

There are many other aspects of the matter that still remain to be explored. What are the relations between absences and tardiness and labor turnover? Cannot absences and tardiness be studied in the same way as labor turnover? What are to be the relations of labor-turnover control to such problems as trade education, promotion policies, the intellectual life of the industrial community, the mobility of labor, scientific management, women in industry? Will it be wiser to leave the broad problem of control of labor turnover entirely in the hands of employers, or should the state have a voice in the control? These are questions both of the present and of the future. In thinking about them and working over them it is important to bear in mind the value of scientific method. The discovery of a unit of measurement, a method of measurement, analysis and classification, has made possible great advances in this one small part of the labor problem.

Let us get the facts in the labor situation,—all of them. Just as Darwin always recorded all facts which tended to contradict his hypotheses, because he knew that unless he did so he would be apt to overlook those facts in order to make his hypotheses triumph, let us also recognize the presence of personal and business interests and bias in ourselves as well as in others. Let us never dodge or shirk the facts. Let us record them so that we and others can study them at any time. Let us measure when means of measurement are obtainable. Let us analyze, weigh, test, and fearlessly experiment. Let us invoke our finest constructive imagination in making our hypotheses. Let us not be dogmatic but humble with our theories, ready to throw them away when new facts are recognized.

Let us last of all never overlook the human instincts. They lie at the heart of our problem. Because of much past neglect in the handling of this question they require the greater emphasis.

It is unquestionably a trait that every person wants to have some sort of control of the circumstances and direction of his own life and of his work as a part of his life. For this reason I believe not only in scientific method and spirit, but I also believe that science must join hands with democracy in order to reach any sound solution of the greatest of all our problems. To find the methods and forms of organization through which such a solution may be obtained is the task that lies ahead of us.

Like the farmer, the engineer is an indispensable factor in the well-being of the nation. He has to deal not with whim and fancy, but with the forces and elements of nature. At bottom his problems involve the utilization and conservation of the natural resources of the nation—the patrimony, as it were, of nature to man. With progress social life becomes increasingly complex. With division of labor comes the efficiency and expertness of the specialist, but also the interdependence of individuals and communities. Only the uncivilized who live upon the gifts of nature are today self-sufficient and independent as regards the necessities of existence. A large city, on the other hand, is always within hailing distance of starvation. The engineer is a product of this interdependent life, and his sway has increased as civilization has grown in complexity. His function has become so specialized that it cannot be dispensed with, and none can substitute in his place. Light, heat, power, sanitation, irrigation, construction, intercommunication—these are vital elements in modern progress.—*Power,* October 23, 1917.

ACCIDENT PREVENTION IN THE TEXTILE INDUSTRY

By DAVID S. BEYER,[1] BOSTON, MASS.

Non-Member

Mechanical accidents form a large percentage of all those occurring in the textile industry. Contributory factors to this condition are (1) an exceptionally large mechanical exposure—the exposure points run into the thousands or tens of thousands for a single plant and it is an extensive problem to guard completely all the belts and gears, (2) female and child labor—a large percentage of the employees are women and youths, and (3) an ever-present temptation to clean machines in motion—there is a natural tendency on the part of the operator to be constantly cleaning or picking the "fly" out of a machine.

There is probably no other industry where so great a weight should be given to mechanical guarding, or where effective guards will produce such important results.

This paper describes the various methods and forms of mechanical protection which are desirable for textile machinery, discusses effective steps toward overcoming difficulties encountered in providing complete safeguards, and codifies definite standards for use in specifying guards for textile machinery.

THE manager of the steel mill handling several hundred tons of molten metal every day, might think that in comparison with his difficulties the mechanical problem involved in turning out a spool of thread or a bale of cloth would be very simple. A study of conditions in the textile industry, however, would soon convince him that the man in charge of a modern textile plant has some problems which are all his own. Many of these problems come from conditions which have a very direct bearing on accident prevention, notably the following:

Mechanical Exposure. In the majority of manufacturing industries the number of machines is less than the number of employees. For example, the combined insurance records from a number of states show the following average conditions:

Earthenware manufacturing, 17 machines per hundred employees.
Furniture manufacturing, 40 machines per hundred employees.
Rubber goods manufacturing, 60 machines per hundred employees.
Printing, 67 machines per hundred employees.

In the textile industry, on the other hand, the number of machines usually exceeds, by several times, the number of employees. Sixty-one characteristic cotton mills contained 33,393 employees and 119,078 machines, or,

Cotton mills....................357 machines per hundred employees

The average cotton mill in Massachusetts has nearly a thousand employees and several thousand machines. These machines are usually belt-driven, and some of them have auxiliary belts in addition to the main driving belt. Most of them have gears at several points on each machine. The exposure points run into the thousands or tens of thousands for a single plant, and it is an extensive problem to guard completely all the belts and gears.

District	Males 16 years and over		Females 16 years and over		Children under 16 years	
	Number	Per cent	Number	Per cent	Number	Per cent
New England States....	76,483	49.0	70,113	45.0	9,385	6.0
Middle States..........	13,852	43.7	15,116	47.6	2,765	8.7
Southern States.........	54,577	45.5	37,885	31.6	27,538	22.9
Indiana and Other States	806	29.4	1,597	58.3	341	12.3
Total..............	145,718	46.9	124,711	40.2	40.029	12.9

Kind of Employees. Another feature of the textile industry that adds to the accident hazard is the fact that such a large percentage of the employees are women and youths, as shown by the data in the preceding table from one of the U. S. Government publications.[1]

These figures were for 1905, and it is probable that the number of young persons employed in the cotton mills has been reduced by child-labor laws enacted since that date. It is undoubtedly safe to assume, however, that at least half of the employees in cotton mills are women and children.

Women are naturally less mechanically inclined than men and are not so likely to appreciate the danger of power-driven machinery. Their clothing and hair are much more likely to become entangled in machinery, thus making the hazard inherently greater for women than for men. The youthful employee is also more likely to be injured through carelessness and as the result of chance-taking or horseplay.

A large percentage of cotton-mill employees are foreigners, to whom it is difficult to explain fully the hazards of their work. Figures from the government report mentioned show that less than 10 per cent of the employees are American or American-born.

Cleaning Machinery. Another condition contributing to the accident hazard in the textile industry is the fine lint or fluff which results from many operations, and which tends to collect in the form of "fly" over the machinery and gets into the gears and moving parts. While this is not likely to injure the machinery, it brings about a natural tendency on the part of the operator to be constantly cleaning or picking the "fly" out of the machine.

Most plants have rules that the machinery shall not be cleaned while in operation, but they are difficult to enforce. Out of a total of 557 mechanical accidents reported by cotton mills to one insurance company, 88 (or about 16 per cent) occurred from cleaning while machinery was in motion. The

tendency to do this is enhanced by the fact that the operators are usually paid on a piece-work basis, hence they do not like to lose any product by having the machines shut down for cleaning.

Thus we have the combination of (1) an exceptionally large mechanical exposure, (2) female and child labor, much of which is non-English-speaking, and (3) an ever-present temptation to clean machines while in motion. Under these circumstances it is not surprising that mechanical accidents form a large percentage of all accidents occurring in the textile industry. That this is actually the case is corroborated by an analysis of accidents in Massachusetts, a state which has approximately one-third of all workmen employed in cotton mills in this country. While mechanical accidents for all industries of the state were only 27 per cent, numerically, of the total number of accidents reported, mechanical accidents in cotton mills were 44 per cent of the total for this

FIG. 1 GUARDS FOR PICKERS

These photographs show an excellent arrangement of guards for belts and chains on pickers. The guards are supported by rods fastened to the framework of the machine, and can be quickly removed by loosening a couple of thumbscrews which secure them to the supports. This permits cleaning the floor underneath the guards without disturbing them, as would be necessary if the guards were supported from the floor. In order to avoid places where "fly" may collect, the guards do not completely enclose the belts and chains, but a transverse section has been placed across each guard, between the two sides of the belt or chain, to prevent danger of a hand being slipped down inside the guard and thus being caught and injured. The projecting end of the beater shaft is protected by a metal cap.

industry, or nearly double the average ratio for the other industries.

An additional study of accidents in the thirteen principal industries of Massachusetts, such as boots and shoes, metal-working, electrical supplies, rubber factories, paper mills, and printing establishments, shows that the lost time per thousand employees resulting from the mechanical hazards of belting, shafting and gearing is three times as great in the cotton mills as the average for the whole thirteen industries.

Mechanical accidents as a class are more serious than non-mechanical accidents.[1] While they represent a little less than one-half of all accidents reported in the cotton industry in Massachusetts, it is probable that they are at least three-quarters of the problem from the standpoint of severity.

While safety education of employees through the organization of safety committees, safety talks, the posting of safety bulletins and signs, etc., are important in this industry, as in all others, there is probably no other industry where so great weight should be given to mechanical guarding, or where effective guards will produce such important results, as in the textile industry.

INTERLOCKING GUARDS

The effort to reduce the mechanical accidents in this industry has resulted in the development of a type of guard which is about as nearly "fool-proof" as any mechanical device can be,—the so-called interlocking guard. In this form of protection the guard is so arranged that it cannot be removed while the machine is running, and the machine cannot be started until the guard is in place.

This result can often be secured by a very simple and inexpensive arrangement; for example, the beater lock shown in Fig. 2. The beater revolves at high speed and the loss of hands and other serious injuries have resulted from employees putting their hands into it while it is running. To prevent such occurrences a disk is keyed to the beater shaft so that it revolves whenever the beater is in motion. Before the beater cover can be raised a projection on the locking arm used to keep the beater cover closed must be slipped through an opening in the disk. This can only be done while the disk and shaft are at a standstill, and so long as the locking arm is in contact with the disk it prevents the machine being started, which means that the cover must be replaced and the locking arm slipped back over it before the machine can be started up. Similar devices are also applied to various kinds of gear covers.

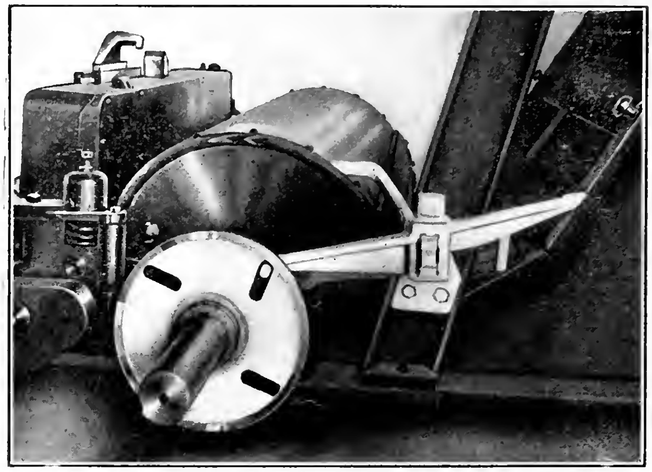

FIG. 2 INTERLOCKING DEVICE FOR BEATER COVER AND DOOR OVER DIRT GRID (PAT.)

In order to open the beater bonnet or the door, a projection on the locking lever (shown in white) must be slipped through the disk on the beater shaft. Obviously this can only be done while the machine is at a standstill. In order to start up the machine again, the locking lever must be slipped out of engagement with the disk, which insures the bonnet and door being closed before the machine is started.

The general application of this principle to textile machinery would eliminate many of the accidents which now occur on account of carelessness or thoughtlessness of the employees.

[1] See paper by the author presented at the 4th Annual Meeting of the International Association of Industrial Accident Boards, and reprinted in the Weekly Underwriter for September 13, 1917. In one state which kept a separate cost record for these classes, the average mechanical accident cost nearly twice as much as the average non-mechanical accident.

WHEN IS A GEAR GUARD NOT A GUARD?

This is a question that has been agitating safety inspectors and plant managers ever since the first gear guard was built. There is a natural desire on the part of everyone to make guards as simple and inexpensive as possible. Unfortunately, this perfectly legitimate desire has resulted in two types of guards for gears which are so ineffective that they have tended to discredit guarding to a certain extent, because accidents still occur after the so-called guards are installed. One is a band over the face of the gear following more or less closely the outline of the gear, but leaving the most dangerous part, the mesh point, exposed sufficiently to admit a finger or even a hand. Another is to provide a guard which protects the mesh point, but which is not carried around the periphery of the gear, and thus forms a shearing action between the teeth of the gear and the edge of the guard at the point where the teeth pass underneath the guard.

Many of the pioneer concerns in the safety movement, such as the United States Steel Corporation, started out by installing gear guards of the above types; but found that they did not eliminate the accidents and later changed them to guards completely enclosing the gears. There are many partial gear guards in the textile industry today, and they sometimes contribute to accident occurrence from the false sense of security they inspire.

An analysis of 550 textile-machine accidents reported consecutively to an insurance company showed that 88 of these

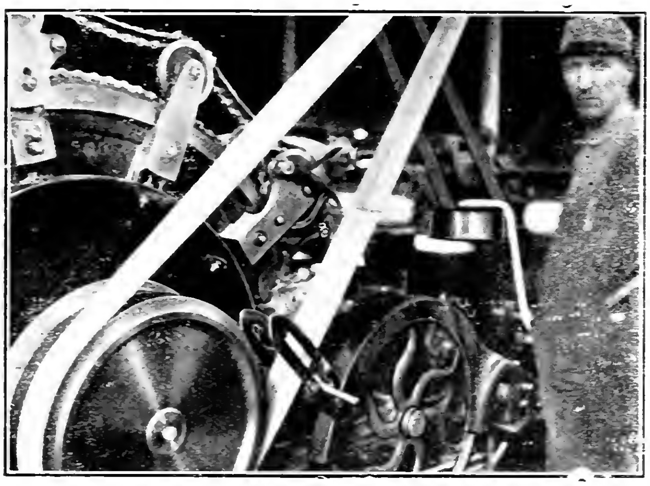

Fig. 3 Belt Shifter for Cards

This shifter can be installed by simply securing it to the circular flange above the pulley by means of one or two set screws. It only requires a few seconds to loosen these set screws and slip off the shifter when it is necessary to reverse the belt for grinding.

accidents, or about 16 per cent, were from gearing; more than a third of the gear accidents were due to cleaning the machinery while in motion.

It is not practicable to apply the interlocking principle to all gearing on textile machinery, but it is practicable to fully enclose the gears; and where the guards are not interlocked they should be firmly fixed in position by cap bolts or other means that make it difficult for the operatives to remove them quickly, and tend to restrict their removal to properly authorized mechanics.

From a list of Massachusetts accidents, out of a total of 1087 gear accidents occurring in one year the cotton mills contributed 400; in addition, the woolen and worsted mills had 236. Thus we see that cotton and woolen mills were responsible for considerably more than half the total number, although they only employed about one-quarter of the workmen engaged in manufacturing industries in the state.

BELT GUARDS

There were 254 accidents from belting in Massachusetts cotton mills during one year and 113 accidents in woolen mills, or a total of 367 for the two industries; this shows that belt guards are also important for textile machinery.

A good many textile machines, such as roving, spinning and twisting frames, have an outboard bearing, supported by a framework around the pulley, that tends to keep employees away from the pulley and offers a certain degree of protection. In addition, these machines are commonly provided with belt shifters, and where the shifter comes down close to the point of contact between the belt and pulley it considerably reduces the chance of anyone being caught at this point, where most of the serious belt accidents occur.

Fig. 4 Belt Guard on Spooler

This shows a belt guard which has been developed by one of the machinery builders. This is a simple and inexpensive type of guard, but taken in conjunction with the outboard bearing and belt shifter it gives quite a good degree of protection.

Several manufacturers of these machines have provided an excellent guard, consisting merely of a semi-circular disk casting or plate which is fastened to the outboard bearing of the machine. This guard only extends a few inches above the contact point between the belt and pulley, and does not guard the upper part of the belt to the height which is commonly prescribed in insurance and other mechanical standards for safeguards.

For other types of machines it is usually impossible for the machinery manufacturer to provide belt guards as an integral part of the machine, on account of the fact that the driving belts lead off at various angles which can only be determined by the local arrangement of each plant. Under such conditions it is necessary for the belt guards to be installed at the plant, after the machinery is in place.

BELT SHIFTERS

Some types of textile machinery, such as roving and spinning frames, have long been equipped with belt shifters as an operating necessity, since the operators need to shut down the machines at some distance from the driving belt.

Other machines, such as cards, are commonly found with-

out shifters. There has been a notion generally prevalent among mill owners that it was impracticable to apply belt shifters to cards on account of the grinding operation, which requires the belt to be reversed. Shifters which are thoroughly practical in operation have been developed, however, and cards, as well as other textile machines, should be so equipped.

OTHER SAFETY PROVISIONS

Various additional forms of mechanical protection are desirable for textile machinery, such as the elimination of all protruding set screws, keys, bolts or other dangerous projections from revolving parts, and the guarding of projecting shaft ends. Crushing or shearing actions in some machines, such as mule spinning frames, should be protected, as should also rope drives on mule frames.

Many eye injuries have been caused by shuttles flying from looms, and shuttle guards are accordingly important for weaving equipment.

Steam heated drums or cylinders of slashers, calenders, etc., should be provided with relief valves, and the use of a reducing valve with pressure gage and safety valve on the low-pressure side of the line is an important item of safety equipment for the steam line supplying auxiliaries of this kind.

There were 1776 accidents in one year in Massachusetts caused by machinery peculiar to the cotton mills, and 903 by machinery peculiar to the woolen and worsted mills.

GUARDING EXISTING EQUIPMENT

Many machines in each textile plant are usually duplicates of one another, so that the pattern for one guard may apply to several hundred machines. Where the guards are made by the manufacturer and the expense of designing guards and making patterns, etc., can thus be distributed over a number of mills, the cost can be reduced to about the lowest possible minimum.

In spite of this condition, however, when we take into consideration the fact that several thousand guards may be required to fully protect the machinery in a single plant, it is evident that the guarding of existing machinery must necessarily be carried along gradually so as to distribute the labor and expense over a period of years.

GUARDING NEW EQUIPMENT

New machinery is constantly being installed, however, and at the present time much of this machinery is going in an unguarded or partially guarded state, even though the machine builders have developed simple and effective guards for most of the dangerous machinery, and will furnish these guards for new equipment at little or no increased cost. This is an inefficient way of handling the matter, as it is often difficult for the mills to design satisfactory guards after the machinery has been installed, and the cost of the latter method is considerably greater. Worst of all from the safety standpoint, workmen are likely to be injured on the unguarded machinery before it can be protected.

Probably the installation of unguarded machines is due more than anything else to the lack of definite safety standards in this country for textile machinery. As matters stand at present the different textile plants have little opportunity to find out what are effective and practical guards which they could use in ordering new machinery. The machinery builder is also in a quandary, on account of the varying requirements of different states and of different plants. If one builder attempts to furnish complete safeguards for his equipment he is likely to be underbid by a competitor who economizes on cost by omitting the guards.

SAFETY STANDARDS FOR TEXTILE MACHINERY

Probably the most effective step toward overcoming these difficulties would be the preparation of definite and authoritative safety standards which could be used by the factory manager in ordering new equipment and by the builder in designing his machinery. If such standards were prepared and given wide, general publicity they would undoubtedly be followed for most of the future installations.

It would seem that this might be an excellent line of effort for the Sub-Committee on Protection of Industrial Workers of the Society, or for a special committee which might be appointed. The textile section of the National Safety Council at its annual Congress in New York, 1917, went on record in favor of such standards, and voted to appoint a committee which would coöperate with any others interested in drawing up safety standards for the textile industry.

Much work in the way of developing satisfactory safety devices for textile machinery has already been done, and provisions such as the following, each one of which has been put into practical use by one or more plants, might well be included in these standards:

General Standards for All Textile Machines

1. All gears and sprockets exposed to contact shall be completely enclosed, or have a band guard around the face of the gear or sprocket with side flanges extending inward beyond root of teeth, of such design and arrangement that a finger, cannot project through, over, around or underneath the guard and be caught in mesh point of gears or contact point of chain and sprocket.

2. All dangerous projections on revolving shafting such as protruding set screws, keys, bolts and couplings, shall be made flush with the surface or effectively guarded in such a manner as will prevent their catching clothing of persons which may come in contact with them. Projecting ends of beater shafts shall be encased or otherwise effectively guarded.

3. Driving belts shall be equipped with mechanical shifters.

Additional Standards for Certain Textile Machines

Pickers. All beater covers and doors which can be reached while the machine is running, shall be equipped with interlocking devices which prevent their being opened while the machine is in operation and the machine being started while the covers are in place.

Cards. Cylinder covers or doors shall be equipped with interlocking devices which prevent their being opened while the machine is in operation and the machine being started until the covers are in place.

Lap Machines and Doublers. These machines shall be provided with interlocking guards which will prevent the operator from coming in contact with the in-running rolls while they are in motion.

Drawing, Winding, Ring Spinning and Twisting Frames, Etc. Covers or doors giving access to head end gearing of these machines shall be equipped with interlocking devices which prevent their being opened while the machine is in operation or the machine being started until the covers are in place. A guard shall be placed in front of the driving pulley which will effectively guard the point of contact between the belt and pulley.[1]

Looms. Looms shall be provided with effective shuttle guards.

There can be no disagreement as to the desirability of accident prevention from the humanitarian standpoint; from the business standpoint, however, it takes on a new aspect when we realize its effectiveness in reducing an important item of manufacturing cost. Accident prevention then becomes of vital interest.

---

[1] Belt guards should also be provided for other machines, but they can usually be furnished more advantageously by the purchaser than by the machinery builder.

BAGASSE AS A SOURCE OF FUEL

By E. C. FREELAND,[1] BATON ROUGE, LA.

Non-Member

The heating value of one pound of average dry Louisiana bagasse has been found by experiment to be 8300 B.t.u., and despite a high moisture content of about 50 per cent, it is therefore a valuable fuel. While in former years not much attention was paid to the drying of bagasse before burning it, many authorities now claim that a great saving can be effected by such a procedure. The calorific value of this important fuel to the sugar industry, as influenced by the high moisture content, and the benefits of preliminary drying are discussed at length, various methods of calculating the fuel value being given, together with notes on devices employed by various sugar houses in its use for steaming purposes.

THE use of bagasse, or megasse, as it is sometimes called, as a source of fuel, dates from the earliest periods of cane-sugar manufacture. Even before vacuum pans came into use, the sugar manufacturer was wont to burn the sun-dried, or even the green, bagasse under the open kettles. When steam was introduced into the sugar factory as a means of heating the cane juice and syrup, bagasse came to be burned under the boilers as a result. The first boilers designed for bagasse burning differed very little from the coal-burning boilers at that time. As more modern improvements were introduced into cane-sugar manufacture, the methods of burning bagasse were also improved upon, so that, at the present time, very efficient bagasse-burning installations have been perfected. A few of these will be described in a subsequent portion of this paper.

Some of the questions one might ask, when seeking information about this particular fuel, are: Of what value is bagasse as a fuel? How does it compare with coal or oil? What is its composition? It may be well to discuss a few of these points.

Bagasse, chemically, consists mainly of a tough fiber, sugar or sucrose, glucose and other reducing sugars (by a reducing sugar is meant one that will reduce Fehling's solution), and water. The fiber content ranges from 30 to 50 per cent; the sucrose from an almost negligible quantity to as high as 10 per cent; and the water from 40 to 65 per cent; the other constituents occur in such small amounts that they may be disregarded. Its composition varies greatly, according to the method and effectiveness of milling the cane; good milling resulting in a bagasse very suitable for burning, or low sugar and water content. In Louisiana the fiber content averages about 40 per cent and the moisture about 53 per cent; the remaining 7 per cent being mainly sucrose.

METHODS OF CALCULATING THE FUEL VALUE OF BAGASSE

There are several methods in use for calculating the fuel value of bagasse. In this country Prof. E. W. Kerr's formula is in general use. According to one of his bulletins, the fuel value of one pound of bagasse is calculated as follows:

The heat value of one pound of dry bagasse, by experiment, is 8300 B.t.u. Assume that the moisture content of a bagasse is 48 per cent, and that this bagasse is burned in a furnace the stack temperature of which is 500 deg. fahr. One hundred per cent minus 48 equals 52 per cent dry matter in bagasse. Fifty-two per cent multiplied by 8300 equals 4316 B.t.u. in the dry bagasse. Assume the temperature of the bagasse as 80 deg. fahr. Then the water in the bagasse will have to be raised from 80 deg. up to its boiling point (212 deg. fahr.), and then vaporized before the bagasse can be completely burned. The calculations for the heat necessary to vaporize this water are as follows:

212 deg. — 80 deg. = 132 deg.; 500 deg. — 212 deg. = 288 deg.

Heat necessary to raise the water in 1 lb. of bagasse to the boiling point = $0.48 \times 1 \times 132 = 63.4$ B.t.u.

Heat necessary to vaporize the water in 1 lb. of bagasse from a temperature of 212 deg. = $0.48 \times 1 \times 970 = 465.6$ B.t.u.

Heat necessary to superheat vapor from 212 deg. to 500 deg. = $0.48 \times 1 \times 288 \times 0.5 = 69.1$ B.t.u., where 0.5 is taken as the specific heat of superheated steam.

Heat lost in the water = $63.4 + 465.6 + 69.1 = 598.1$ B.t.u.

Net heating value of 1 lb. of bagasse = $4316 - 598.1 = 3717.9$ B.t.u.

Prinsen Geerligs, the noted authority on cane-sugar manufacture, has introduced the following formula for calculating the fuel value of bagasse, according to its composition:

Calorific value in B.t.u. of 1 lb. bagasse = (8550 × per cent fiber) + (7119 × per cent sucrose) + (6750 × per cent glucose) — (972 × per cent water)

The results obtained by using this formula compare very well with the results obtained by burning the fuel in a calorimeter. The one point in favor of using Professor Kerr's formula is that it does not require a complete chemical analysis of the bagasse, while in using the latter a complete analysis is absolutely necessary.

It has been found that the average Louisiana bagasse has a calorific value of about 8300 B.t.u. per pound of dry bagasse and from 3620 B.t.u. gross (with bagasse containing 56.7 per cent moisture) to 4800 B.t.u. gross (containing 42.8 per cent moisture). The net heating values are respectively 2200 and 3350 B.t.u. It is thus seen that the heating value per pound ranges between wide limits, according to the moisture content. In all of the above, 5 per cent was allowed for radiation and no excess air present. The calorific value of Cuban bagasse approaches that of Louisiana very closely for a given moisture content, but for a given per cent extraction on weight of cane the calorific value of a pound of Cuban bagasse is greater than that of a pound of Louisiana bagasse, due to a lower moisture content of the Cuban product. The results given in the tables at the top of p. 920 are typical.

The Louisiana varieties of sugar cane yield from 400 to 580 lb. of bagasse per ton of cane, or on an average of 20 to 30 per cent of the total amount of cane ground. In a 1000-ton house (1000 tons every 24 hours) this would amount to about 480,000 lb. a day, or from 19,500 to 21,000 lb. per hour.

One pound of bagasse will evaporate from 2 to 3½ lb. of

[1] Louisiana State University.

For presentation at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 4 to 7, 1917. All papers are subject to revision.

With an 80 per cent juice extraction on weight of cane:

Variety of Bagasse	Moisture, per cent	Fiber, per cent	Heating Value, B.t.u. per Lb.	
			Total	Net
Cuban	32.8	60	5628	4092
Louisiana	42.8	50	4816	3345

With nearly equal moisture contents:

Variety of Bagasse	Extraction, per cent	Moisture, per cent	Fiber, per cent	Heating Value, B.t.u. per Lb.	
				Total	Net
Cuban	75	42.6	48	4807	3335
Louisiana	80	42.8	50	4816	3345

(For a table of this kind, see La. Bulletin 117, p. 45.)

water "from and at 212 fahr." Assuming coal and fuel oil to have, respectively, calorific values of 14,000 and 19,000 B.t.u. per lb., then from 4 to 6 lb. of bagasse are equivalent to 1 lb. of coal and from 43 to 65 lb. equivalent to 1 gal. (about 7.6 lb.) of oil.

Professor Kerr found, in his latest tests at Louisiana sugar houses, that the bagasse from one ton of cane generated from 1.16 to 1.44 boiler horsepower. Thus the bagasse from a 1000-ton house for 24 hours will generate from 1160 to 1440 boiler hp. during that period of time. It would require about 60 tons of coal per day to do the same work, assuming that the coal equivalent of the bagasse from 1 ton of cane is 120 lb. It is thus seen that bagasse plays an important role as a source of fuel in the sugar house.

METHODS USED IN DRYING BAGASSE

In former years not much attention was paid to the drying of bagasse before burning it. It was was the custom either to sun-dry it or feed it to the furnaces in a wet condition, just as it came from the mills. Of later years, however, many devices have been put into use in order to dry it partially before it is burned.

In Mauritius, apparatus known as "secheries" have been put into use for this purpose. They consist of a chamber near the chimneys, in which is arranged a system of belts alternately traveling in opposite directions. The flue gases go through this apparatus, and thus the waste heat of the gases is utilized to dry the wet bagasse. In countries where labor is cheap and fuel high, as in some parts of Egypt, other devices, whereby the bagasse is conveyed around the smoke-stack and smokebox of the boilers by means of a screw-like conveyor, have come into use to remove part of the moisture from the bagasse.

A very efficient bagasse drier has been designed by Professor Kerr (La. Bulletin 128), which is in the form of a tower-like structure. The bagasse is conveyed to the top and falls downward over a series of inclined shelves placed opposite each other. The dried bagasse is conveyed from the bottom of the drier to the furnaces. The furnace gases are used to dry the bagasse and are conveyed to the bottom of the drier and pass upward, the hottest gases coming in contact with the driest portion of the bagasse. An induced-draft system is employed, the fan being placed near the top of the drier.

Of late, especially in Cuba and Hawaii, in large factories stokers are being put into use to dry bagasse. These stokers are mainly of the step-grate type, some with front feed and others with double feed. The bagasse is fed at the top or upper back part of the stoker in the same manner as coal. They have proved to be very efficient as a means of drying bagasse, as well as in regulating the combustion or burning of the bagasse.

As to the economy of bagasse drying, many authorities claim that a great saving can be effected by drying this fuel before it is fed to the furnaces. This has been proved as a result of many experiments. Noel Deerr states that in Mauritius he found that bagasse entering a secherie with 50 per cent of moisture would leave containing only 35 per cent; this amount of water corresponds very closely with the evaporation of half the original moisture. In a calculation of the heat lost in the flue gases, he found that 565 B.t.u. per lb. of bagasse were carried away in the associated water; a saving of half of this would be 282 B.t.u., reducing the heat carried away in flue gases from 1675 to 1393 B.t.u.; or, expressed as a percentage on the total heat of 1 lb. of bagasse, the loss in the flue gases is 30.4 per cent as compared with 36.6 per cent loss calculated for wet bagasse. Professor Kerr says that in Louisiana 16 per cent of the total heat generated by the combustion of 1 lb. of bagasse is required to evaporate the moisture present. About 14½ per cent of the moisture in Louisiana bagasse was removed by drying it, and the dried bagasse had a heating value 55 per cent greater than the wet bagasse. This means that a saving of over 2½ gal. of oil will be effected per ton of cane ground. In a factory grinding 60,000 tons of cane per season this means a saving of about 154,000 gal. oil, or 3670 bbl., which, at $1.25 per bbl., means a saving of $4,587.50 per season.

BOILER FURNACES FOR BURNING BAGASSE

As has been said before, bagasse was formerly burnt in furnaces very similar to those used for burning coal. During recent years, however, many improvements have been made along this line. In present practice furnaces of the Dutch-oven type are very widely used. Boilers of all types, including those of the Scotch-marine type, are used in connection with the Dutch-oven type of furnace.

The following shows the types of boilers in use at a few Louisiana sugar houses:

House	Type of Boiler
Angola	Horizontal return tubular, with Dutch oven and small draft fan.
Cinclare	Scotch marine, with suspension furnaces and Dutch oven.
Poplar Grove	Stirling, with Dutch oven.
Adeline	Horizontal return tubular, with large and elaborate combustion chamber.
Vermilion	Horizontal return tubular, with Quinn flat-top furnace.

Other types in use in Louisiana (given in Bulletin 117, La. Expt. Station) are: Babcock and Wilcox; Cook water-tube (vertical tubular); Climax water-tube (vertical tubular); and various types of boilers of the "half" and "full" Dutch-oven types.

In Demerara the Abel type of furnace is used in connection with the standard types of boilers. By using this furnace the

heated gases of combustion pass three times along the boiler. The essential difference between the Dutch-oven and Abel type of furnace is in the size of the combustion chamber, which in the latter type is much larger.

In Louisiana, the combustion chambers of sugar-house boilers are, in general, large. Where oil is burned in connection with bagasse, which is the case in many houses, there is a tendency to make the combustion chamber smaller as the burning oil causes a better combustion of the bagasse, the furnace temperatures being higher when burning these two fuels together than the furnace temperatures obtained by burning either of them alone.

The grate surface should be small in furnaces used for burning bagasse, as the rate of combustion is high, sometimes running as high as 300 lb. per hr. per sq. ft. of grate surface. This corresponds to about 20 boiler hp. per sq. ft. of grate surface. Some of the recently installed 500-hp. boilers in the tropics have only 25 sq. ft. of grate surface. Small grates require less manipulation and care in order to prevent excessive air losses than is the case with large grates, there being less danger of portions of the grate being uncovered, etc. The amount of grate surface per boiler hp. also varies with the amount of moisture in the bagasse—the less moisture there is, the smaller the grate surface can be made. In Professor Kerr's recent tests, the highest rate of combustion was at Adeline (225 lb. bagasse per hr. per sq. ft. of grate surface), while the lowest was at Vermilion (85 lb. per hr. per sq. ft.); corresponding to about 15 and 6.5 boiler hp. per unit area, respectively. It is probable that a mean between these two sizes would be good practice.

TABLE 1 DATA ON BOILER TESTS AT LOUISIANA SUGAR HOUSES

Item	Sugar House		
	Adeline	Angola	Vermilion
Bagasse burnt, per hr., lb...	3777 to 5614	2345 to 3441	3586 to 3687
Moisture in bagasse, per cent..	45.4 to 53.0	53.1 to 58.6	46.3 to 47.0
Grate surface, sq. ft	25	25.89	42
Heating surface, sq. ft. ...	2500	1512	2450
Equivalent evaporation from and at 212 deg. per hr., lb.	8636 to 13093	2197 to 6476	9131 to 9469
Bagasse burnt per hour per sq. ft. of grate surface, lb....	151 to 225	79.6 to 119	85.4 to 87.8
Steam pressure, lb. per sq. in. abs....	97 to 119	87.8 to 105	108.7 to 109.[illegible]
Quality of steam, per cent dry	98.3 to 99.8	98.5 to 99.6	98.5 to 98.7
Draft in flues, in. of water	0.464 to 0.634	0.300 to 0.487	0.417 to 0.434
Equivalent evaporation from and at 212 deg. per lb. of bagasse, lb............	2.13 to 2.35	1.36 to 1.90	2.48 to 2.64
Efficiency of furnace and grate, per cent.	a56.83 to 64.61 b63.17 to 71.9	a48.96 to 60.[illegible] b55.26 to 67.6	a61.15 to 66.65 b[illegible]7.65 to 73.81

It is the practice in Louisiana to use systems of forced or induced draft as a source of air supply. Bagasse contains a great amount of air, but when burned on a small amount of grate surface, with a high rate of combustion, it requires a high draft. When, however, it is burned in furnaces having a large combustion chamber and a large surface, air in nearly all cases is supplied in great excess, which lowers the efficiency of the boiler and grate. Where forced draft is used in Louisiana, the general tendency, it is found, is to supply air in great excess.

In order to show comparative figures on boiler tests at Louisiana sugar houses, a partial list of results is given in Table 1, which shows in each case the highest and lowest values obtained.

In calculating the efficiencies in Table 1, the following methods were used: Efficiency a = heat leaving in steam per lb. wet bagasse divided by net heating value of 1 lb. of wet bagasse [gross heating value per pound minus (heat necessary to vaporize moisture present in it plus heat necessary to raise to stack temperature)].

Efficiency b = heat leaving the steam per lb. wet bagasse divided by [net heating value per pound (same as above) plus heat required to vaporize moisture formed by the combination of the hydrogen and oxygen in the fuel]. It is probable that the latter method of calculating efficiencies is more suitable for making comparisons where there is a considerable variation in the quality of bagasse.

In conclusion, it may be said, that, although many recent improvements have been made in the methods of burning bagasse, there are yet many fields open along this same line. Methods of regulating the air supply, improvements in furnaces and driers, and utilization of the heat in the waste flue gases are some of the problems being worked upon by the sugar-house engineer of today, with a view of conserving as much of the heat as possible furnished by this most valuable by-product of the sugar house.

The latent heat of steam of standard pressure and temperature is a fundamental constant, the value of which has long been less satisfactorily known than was desirable. The values given in Kaye and Laby's Physical and Chemical Constants differ appreciably, ranging from the 537 calories of Regnault obtained in 1847 to the 540 calories found by Joly in 1895. A new determination is described in a paper by Mr. T. Carlton-Sutton, published in a recent issue of the Proceedings of the Royal Society. The plan of the experiments consisted in weighing the quantity of steam condensed upon a bulb, both when empty and when filled with water. From the two observations the latent heat can be deduced, the value found being 538.88 mean calories. It is claimed that this figure is correct to the fourth significant figure.—*Engineering*, August 24, 1917, p. 200.

One of the great events of the war has been to create a tremendous demand for labor at a time when a vast quantity of the best grade of labor formerly available has been taken away from useful occupations. According to the latest data published in the daily press, approximately 37,000,000 men are now engaged on the fighting lines. Somebody had to take their places. Part of their work is being done by machinery through an increased employment of automatic and semi-automatic machines, but a large share of the work could be done only by human agencies, and even where automatic machinery is employed, back of the engine must be the human hand.

Women have had to be called in, therefore, to take the place of men, and all indications point to an increased demand for female labor, at least in the next few years. In this connection the discussion of Female Labor's Place in Automotive Industry, by Allen Sinsheimer, is of interest, as the writer goes into a number of particular details. From what he states, it appears that female labor may be very advantageously employed in certain lines under certain reasonable conditions. On the other hand, it appears also from a quotation of a statement by Samuel Gompers relating to German war conditions that female labor may be easily abused with most disastrous results to the women thus misemployed.

THE STEAM MOTOR IN THE AUTOMOTIVE FIELD

By E. T. ADAMS, SYRACUSE, N. Y.

Member of the Society

At the present time the question as to the relative fitness of the gasoline as compared with the steam motor for automotive service is receiving most serious attention. New developments and new inventions in steam motors have revolutionized the status of steam at the very time when the oil industry has reached a position absolutely the reverse of that which led to, and fostered, the growth of the gasoline engine. Two interrelated economic developments are especially noteworthy. First is the tremendous increase in the demand for automotive power. The use of the automobile has become universal, the use of the truck is at the beginning of an era of expansion which may prove equally great, and the farm tractor marks the beginning of a demand greater than all the others. The farm is the greatest single user of power; few people realize how huge a portion of the earth's surface must annually be cut into slices, turned upside down and pulverized to form a seed bed, or the expenditure of power which this involves. The excellence of the gasoline motor has led to its adoption for this and for other service for which it is economically unfitted, and we are fast working toward a condition where gasoline alone is not produced in sufficient quantity to meet the demand.

The tremendous increase in the demand for automotive power has outdistanced the ability of the gasoline engine to meet this demand, chiefly for the reason that the supply of fuel is not now equal to the requirements.

The steam unit has many advantages for automotive service. Its high torque at low speed, its overload capacity, its smooth, flexible speed and power control have remained the standards of excellence reached for but never attained by any gasoline motor.

The design of the steam unit is simple, and many features of construction have been introduced which tend toward long life and low cost of upkeep.

The difference in cost between gasoline and power oil, when coupled with a reduced cost of lubricating oil, represents an appreciable reduction in fuel cost in favor of the steam unit and one of importance to the truck and tractor operator.

Numbers of new steam trucks, tractors and pleasure cars are in service, or in process of manufacture or design. This effort and this demand will have a profound influence on the automotive industry.

Second is the fuel situation. When the automobile industry was young the oil industry was dependent on the use of oil for light, and gasoline was a by-product,—cheap, abundant and of excellent quality. Today the oil industry is based on oil for power, and gasoline is its foremost product. The supply, even with lowered quality and new processes of manufacture, is not equal to the demand, and the price is too high for many commercial uses. There will be some gain due to the perfection of vaporizing types of carburetor which will permit further lowering of the quality of gasoline, and some gain due to increased attention to economy, but the growth of the use of power in this field will be greatly hampered unless there is an increase in the quantity of fuel available far greater than can be expected from this source alone. This means the use of oils other than gasoline, and of methods other than carburetion and burning in an internal-combustion engine.

The steam-driven motor is the type which most readily meets this condition, and its use will receive a further impetus because the demand for gasoline is a seasonable demand and a steam unit using unpurified kerosene or similar light distillates will use these by-products of gasoline manufacture during the season in which they are produced. These by-products are produced in great quantities, are relatively cheap and furnish an ideal fuel for the small-power steam boiler.

The steam unit has many advantages for automotive service. Its high torque at low speed, its overload capacity, its smooth, flexible speed and power control have remained the standards of excellence reached for but never attained by any gasoline motor. The connection from motor to axle is simple and direct, without clutch, reverse or change gears. Steam is available at full boiler pressure and for practically full stroke to give torque to lift a loaded rear axle slowly and gently from a rut. Ahead and reverse follow the movement of a single lever, and acceleration and hill-climbing capacity hitherto unknown are at the operator's command.

High steam pressures and temperatures have been the rule, but a light, compact motor construction and high economy are attainable with steam pressures between 400 and 500 lb. gage, and thereby we avoid the tendency to carbonize the lubricating oil which is found at higher temperatures. There has been much interesting speculation on the economies due to the use of higher steam pressures and the best division of a given total heat between superheat and the temperature due to evaporation. But in the small units here considered, practical considerations such as have been outlined will doubtless govern design.

The chief force which is bringing about the increased use of the steam motor is its superior fitness for automotive service, especially in the commercial field. First, in truck service the upkeep of the gasoline truck, even with the expert service, is now beyond reason and is a serious handicap to the business. Overloading and incompetent handling are blamed for this condition, but, practically, overloading is not preventable, and starting from a bad position is an unavoidable hazard. Racing the motor, coupled with the sudden application of the clutch, is the only answer to these conditions which the gasoline motor affords. The result is destructive to both power plant and transmission. The steam motor meets this situation by using steam for practically the full stroke of the piston and at any pressure which the tractive power of the wheel will permit.

For presentation at the Annual Meeting of The American Society of Mechanical Engineers, New York, December 4 to 7, 1917. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

The available mean effective pressure on the steam piston under these conditions is fully five times the maximum available with a gasoline motor, and the motor speed for the same torque may be correspondingly low. With the steam unit the load is picked up gently, exactly as a locomotive starts a train. This tends toward low cost of upkeep.

Another point in favor of the steam unit is the extreme simplicity of the transmission—one pair of bevels or spurs, or direct drive on the worm shaft is all that is required for light and moderate power work, with one additional reduction for heavy work and tractor service. There is no clutch, no reverse gear—only a simple direct drive from motor to axle. This again tends toward low upkeep and long life.

In early constructions the motor naturally followed locomotive or marine lines. Modern steam motors are preferably of the multiple-cylinder type, designed for quantity production using the tool equipment and shop methods of the modern gasoline-motor manufacturer. They are carefully balanced, are light and simple and capable of as high speed as may be desired. The uniflow type is largely used because of its simplicity and its high economy when operated non-condensing. Because of the high steam pressure, the most economical mean effective pressure is about the same as the full-load m.e.p. of the gasoline motor, and for the same power the cylinder sizes are about the same in the two cases. With this construction piston and valve require but little lubrication, the amount of lubricating oil necessary being far less than that used by older types of steam or by modern types of gasoline motors. The pistons and rods follow automobile practice. Alloy steel and aluminum are freely employed and ball-bearing construction is used where possible. Crankshafts and pins are oiled by a forced-lubrication system, bearing areas are ample, and the labor cost for adjustment and repair is naturally extremely low.

Boiler design exhibits greater variety than any other portion of the steam unit. The cylindrical fire-tube types, both with and without a water leg, have their advocates. The ordinary flash type is in use but not so much in favor, due, among other things, to its especial tendency to carbonize any lubricating oil introduced with the fuel. Tube boilers with natural or forced circulation are popular and effective. A forced circulation, contraflow-tube type seems especially commendable in that it may be forced to almost any degree and is, therefore, responsive, light, compact and economical. The stack temperatures are readily brought down to 50 deg. above feed temperatures; the superheat is under good control and danger of burning or injury to the tubes is negligible. One advantage of the tube type is its absolute safety from destructive explosions.

All these features exhibit a very great advance over older constructions. They are popular because of their economy and safety, and because all these improvements tend toward longer life and lower cost of upkeep.

The furnace is the most important feature of the modern unit. All precedent is swept aside. With a light power oil as the established fuel, there is no excuse for following old practice and merely firing oil into a combustion space originally designed for coal, and in later designs this is not done. First, proper conditions are established for burning the oil; second, proper conditions are established for utilizing the heat thus generated, and these are then combined. In one installation this leads to a design with the furnace practically at the top of the boiler, with force feed of oil and air; this has proved a most acceptable and desirable location.

Various methods of controlling the oil are in general service. In the oldest type the oil under pressure is converted into a highly superheated vapor, which discharges past an adjustable needle valve drawing with it an air supply, fed and controlled as in a bunsen burner. After proper mixing the mixture is burned as it issues from fine perforations in the grate. A pilot light which keeps the oil supply superheated is a necessary part of the equipment. In spite of its high economy and its honorable record in service, this system is steadily being displaced in the more modern designs. Objection is made that under certain conditions the pilot light and the heated oil under pressure are highly dangerous, and the clogging of the control valve by carbon and tars formed by the cracking of the oil is objectionable and expensive.

The mechanical atomizer of the type used in larger furnaces and with heavier oils does not appear in use, but would seem to be well suited to the service. New systems of this general class are being very extensively tried out. These systems are important because they consider not only the proper burning of the oil, but also the commercially more important item of control. Considered as a unit, the vital control of the motor must be at the furnace. There must be control in proportion to load, to steam pressure, and to maximum steam temperature, and also control directly responsive to the demands of the public. In a pleasure car, starting from cold, there must be steam to enable the car to be driven away in one minute. The mechanism or control, to be commercially successful, must be no more burdensome than the movement of a lever or the throwing of a switch. In a truck or tractor the demands are somewhat more moderate; but in general the steam unit must be practically on a par, in the matter of starting, with the gasoline unit, and the fact that in this respect also steam is now on a par with gasoline is one reason for the present impetus toward steam.

Where both air and oil are metered in under forced draft and in a boiler as flexible as those here described, it appears that a simple and entirely satisfactory method of heat graduation is to "cut in and cut out"; that is, to stop the supply of both oil and air entirely where it is desired to limit pressure or temperature, and to cut in again at full power when the pressure or temperature falls, this action, of course, being entirely automatic. With the safety which a tube boiler provides, a satisfactory system of water supply is a feed pump operated by any means whose speed or time of operation is directly proportional to the load. This involves attention to the water level and occasional adjustment by the operator, but as there is no serious penalty for his failure this seems an entirely satisfactory method—perhaps more satisfactory than a type more strictly automatic.

Next to the fuel situation and the desire for reduced cost of upkeep, this new system of control is the most important development affecting the renaissance of the steam motor in the automotive field.

The exhaust is condensed to atmospheric pressure in an ordinary type of automobile radiator. The type with wide surfaces and thin water spaces has proved most effective. In a pleasure car complete condensation is secured in a small radiator often without the use of a fan. The efficiency of the radiator is reduced by excessive oil in the feed, but otherwise there are no disagreeable effects. Under these conditions fresh-water supply is only needed at rare intervals, which again is a feature which has served greatly to increase the demand for the steam motor.

It is characteristic of the internal-combustion motor that it gives its highest economy at its maximum load, with rapid reduction in economy as the load is decreased. The reverse is

time of the steam unit. It results from this that under usual operating conditions the steam unit is operating at its maximum efficiency, whereas the gasoline unit is operating at only fair efficiency. These efficiencies tend to meet, and in the two cases in actual service the quantity of fuel per brake horsepower should not be materially different.

The difference in cost between gasoline and power oil, when coupled with a reduced cost of lubricating oil, represents an appreciable reduction in fuel cost in favor of the steam unit and one of importance to the truck and tractor operator. In the case of the automobile where a small horsepower represents great mileage, this item is of lesser importance; but it lends romance to engineering to note that the joy of driving the smooth, flexible steam motor is likely to cause its extensive adoption first in the field which commercially needs it least.

WORK OF THE BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in The Journal, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 174-176, inclusive, as formulated at the meeting of September 20, and approved by the Council on October 12, 1917. In this report, as previously, the names of inquirers have been omitted.

Case No. 174

Inquiry: What type of stays does Par. 200 of the Boiler Code refer to in its requirements for the drilling of tell-tale holes in their ends? The rules of the Interstate Commerce Commission establish the distinction that all stays shorter than 8 in. in length shall be termed staybolts.

Reply: It has been proposed to revise Par. 200 to read as follows:

> 200 *Staybolts.* The ends of screwed staybolts shall be riveted over or upset by equivalent process. Staybolts must be hollow or the outside ends of solid staybolts, 8 in. and less in length, shall be drilled with a hole at least 3/16 in. diameter to a depth extending at least 1/2 in. beyond the inside of the plates, except on boilers having a grate area not exceeding 15 sq. ft., or the equivalent in gas or oil-fired boilers, where the drilling of the staybolts is optional. Solid staybolts over 8 in. long and flexible staybolts of either the jointed or ball and socket type need not be drilled.

Case No. 175

Inquiry: Is it necessary under the rules of the A.S.M.E. Boiler Code that the outside firebox plate of locomotive type boilers be of the same thickness as the barrel sheets when it is reinforced by stays to the inner firebox sheet? It is customary in locomotive boiler practice to make the outside firebox plate of less thickness than the barrel plate for reason of this staying.

Reply: The Committee now has this matter under consideration and will render a formal reply as soon as the investigations now under way have been completed.

Case No. 176

Inquiry: What factor of safety shall be used under the rules of the Boiler Code, *a.* when the longitudinal joint of a dome less than 24 in. in diameter is lap riveted, and, *b.* when such dome is attached to the shell of the boiler by a flanged ring construction in accordance with Par. 261?

Reply: When the longitudinal joint of a dome less than 24 in. in diameter is lap riveted, the longitudinal barrel of the dome must be designed on the basis of a factor of safety of not less than 8. When such a dome is attached to the shell of the boiler by a flanged ring construction, in accordance with Par. 261, the flanged construction shall have a factor of safety of not less than 5, but this does not involve any change in the factor of safety of not less than 8 in the dome barrel.

The Governor of Michigan has appointed the following men as members of the Board of Boiler Rules, in accordance with the terms of the Hanley Act, passed by the legislature last winter: G. W. Bissell, East Lansing; E. C. Fisher, Saginaw; J. C. McCabe, Detroit; S. Milan, Grand Rapids; G. E. Christensen, Houghton.

Autogenous welding entered upon what is bound to be a fruitful period when recently in the Engineering Societies Building, New York City, committees of various societies and manufacturers met and formed the National Welding Council. All the industries were represented, together with the insurance companies and the constituted authorities, such, for example, as represented by J. C. McCabe, safety engineer for the City of Detroit.

The purpose of the National Welding Council is, in the beginning, at least, divided into four divisions, to accomplish the following ends: Uniformity of design of pressure vessels to be autogenous welded; licensing of welders for pressure-vessel work; research to determine an infallible test that will reveal unsafe welds, and fourth, to investigate the microstructure and physics of welds. As autogenous welding is so attractive on account of both the cost and the time of doing such work, the development of the art as applied to pressure vessels suffers because engineers who represent the public as well as private interests cannot be certain of the safety of an autogenous weld. The frank statements by Mr. McCabe, and by the insurance interests represented at the meeting by T. T. Parker, of the Fidelity and Casualty Co., and J. G. Shaw, of the Travelers Insurance Co., were most commendable. These gentlemen gave the welders to understand that until some reliable tests that would enable one to determine the safety of a weld had been found, they would not permit of the use of welds in pressure vessels subject to tension. This also is the attitude of responsible engineers, many of whom have applied welds to pressure vessels that are unlikely to rupture or other accident, and which, if ruptured, will not cause serious damage to surrounding property or loss of life.—*Power*, Oct. 9, 1917.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Inspection in Munitions Manufacture

To the Editor:

In his paper on The Importance of Intelligent Inspection in Munitions Manufacture, presented at the Spring Meeting of the Society at Cincinnati in May of this year, Mr. Walsh put forth some statements and considerations in regard to difficulties experienced in the inspection of big artillery orders in the United States in 1915-16.

The members of the Russian Artillery Commission readily acknowledge the justice and value of Mr. Walsh's statements, as well as those in other papers presented at the same meeting.

Unfortunately for some who were not familiar with the execution of an order by the Canadian Car & Foundry Company for 5,000,000 3-in. shrapnel and high-explosive shells for the Russian Government, some expressions in Mr. Walsh's paper and examples used in his illustrations may be understood in an undesirable way from the standpoint of the Russian Commission, and may be interpreted and generalized in such a way which, we hope, the author himself did not have in view.

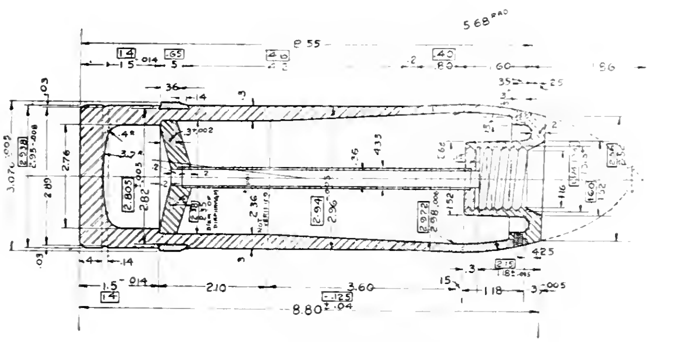

Fig. 1 Additional Tolerances for Russian Shells

For example, in Par. 2 Mr. Walsh states: "Russia was as little prepared to provide the required number of qualified inspectors as was the contractor, and in consequence the manufacturer had inflicted upon him so-called inspectors who were selected from every walk in life, it seemed, except the mechanical, and barbers, bartenders, butchers, students and teachers were the usual thing and the practical man the exception."

The inspectors who were selected, as the author justly points, "from every walk of life except the mechanical," were not, in reality, the Russian inspectors, but the inspectors of the contractors, who were eventually taught by the Russian representatives. Naturally, the provision of all the necessary number of inspectors from Russia to America during the war could not and should not be realized. The Russian Government sent to the United States, as it did to Japan, England and France, a small contingent of skilled inspectors, under the supervision of whom were the American inspectors.

We readily admit that even an inspector thoroughly familiar with his business is not free sometimes from extreme strictness, and sometimes even from so-called "discretion," but we wish to draw attention to the fact that every sub-contractor, for whom each requirement of the inspector results in a loss of money, is naturally inclined to exaggerate, in a disadvantageous manner, the actions of the inspectors, so it would be well to look upon such statements with prudence, and particularly when such statements cannot be verified. That, in the main, the Russian inspection was not too strict is indicated by Fig. 1 given herewith, which shows additional tolerances which, it is true, were not announced to the factory and which were used by the Russian representatives, and only owing to which, however good the production, can be explained the fact that the whole quantity of finally rejected shells did not exceed 1 to 1½ per cent.

It is interesting to note in respect to this, that out of the total number of accepted complete rounds, only 40 per cent of that number were fully in accordance with the contract specifications; the other 60 per cent did not conform with contract specifications.

All Russian inspectors who had an opportunity to see Mr. Walsh's paper cannot help but agree with the statements made by him in Pars. 5 to 12 with regard to technicalities of inspection.

Russian 3-in. Shell Department,
Captain S. N. Petrenko.

Heat Transfer in Condensers

To the Editor:

The transfer of heat in surface condensers is a subject which has frequently been discussed in the Society's proceedings, so that the following method of determining one factor may be of interest.

The design of surface condensers, water heaters, and, generally, any apparatus for the heating or cooling of fluids where the hot medium is never mixed with the cold one, requires the determination of the mean temperature difference.

Suppose two fluids, A and B, to enter a vessel in separate compartments for the interchange of heat.

Let T_1 = temperature of fluid A at the point at which it begins to have contact with fluid B

T_2 = temperature of fluid B at the point at which it begins to have contact with fluid A

T_3 = temperature of fluid A at the point at which it ceases to have contact with fluid B

T_4 = temperature of fluid B at the point at which it ceases to have contact with fluid A.

Then, for parallel flow, Fig. 1, the difference in temperature at the beginning of contact is $T_1 - T_2$, and the difference where the fluids cease to have contact is $T_3 - T_4$.

For counter-current flow, Fig. 2, the difference in temperature at beginning of contact is $T_1 - T_4$, and the difference where the fluids cease to be in contact is $T_3 - T_2$.

If the differences in temperature are represented by D_1 and D_2, then

For parallel flow, $D_1 = T_1 - T_2$ and $D_2 = T_3 - T_4$.

For counter-current flow, $D_1 = T_1 - T_4$ and $D_2 = T_3 - T_2$.

Let D_m = mean temperature difference; then, according to Hausbrand,[1]

$$D_m = \frac{D_1 - D_2}{\log_e (D_1 / D_2)}$$

This formula can be equally well written

$$D_m = \frac{D_2 - D_1}{\log_e (D_2 / D_1)}$$

as can be shown by a simple algebraic proof. Hence it makes no difference whether D_1, as determined by the rule above, is greater or less than D_2. The numerator of the fraction must always be positive, and the denominator must be the Napierian logarithm of an improper fraction.

In determining the design of a piece of apparatus it is often necessary to solve this formula three or four times, as it rarely happens that stock designs will fit a specific case exactly. It is also often desirable to determine the effect upon the apparatus of slight changes in the conditions.

A ready means of solving the formula rapidly is shown in the calculating chart, Fig. 3, which will give solutions in a few seconds, accurate enough for all practical purposes. The chart

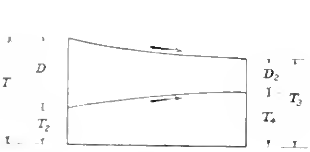

FIG. 1

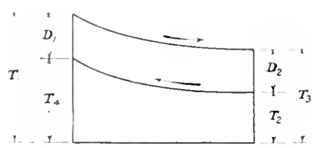

FIG. 2

Fig. 1 Fluids Entering Compartments in Parallel Flow
Fig. 2 Fluids Entering Compartments in Counter-Current Flow

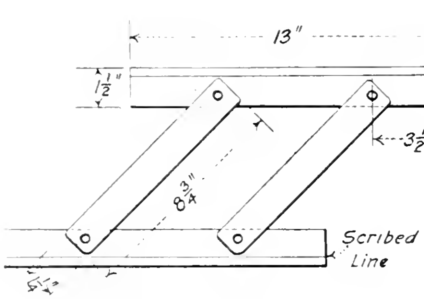

Fig. 4 Scribed Parallel Rule

is made up of four scales: On the left-hand side of the left-hand scale the values of D_1 are plotted; the right-hand scale contains the values of D_2; the difference between these quantities, $D_1 - D_2$, is plotted on the right-hand side of the left-hand (D_1) scale; the diagonal scale gives the values of D_m, the mean temperature difference.

To use the chart, join the given values of D_1 and D_2 with a straight line, and draw a line parallel to this line through their difference, $D_1 - D_2$. This line will intersect the D_m scale at the required value.

An example will show the procedure. Steam enters a closed parallel-flow heater at 215 deg. fahr. and water enters at 50 deg. fahr.; the steam leaves at 212 deg. fahr. and the water is heated to 180 deg. fahr.

[1] Evaporating, Condensing and Cooling Apparatus, by E. Hausbrand. For Hausbrand's formula, see Trans. Am.Soc.M.E., vol. 32, pp. 1151 and 1211.

$T_1 = 215$
$T_2 = 50$ $\qquad D_1 = T_1 - T_2 = 215 - 50 = 165$
$T_3 = 212$ $\qquad D_2 = T_3 - T_4 = 212 - 180 = 32$
$T_4 = 180$ $\qquad D_1 - D_2 = 165 - 32 = 133$

Join 165 on D_1 scale with 32 on D_2 scale and draw a parallel line through 133 on the $D_1 - D_2$ scale; this cuts the D_m scale at 81.2, the required value of mean temperature difference. Numerical solution gives the answer as 81.05.

The chart depends upon the principles of similar triangles. A proof of the principles upon which it is constructed may be found in the *Journal of the Western Society of Engineers*, February 1911, Vol XVI, No. 2, p. 112.

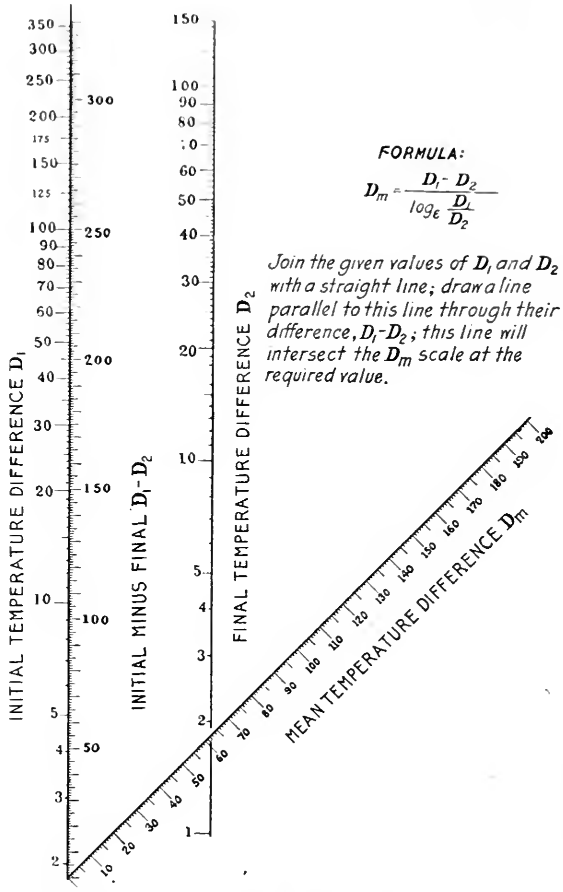

Fig. 3 Chart for Determining Mean Temperature Difference

A convenient device for using the chart is a parallel rule made of transparent celluloid about 0.025 in. or 0.03 in. thick, with fine lines scribed on the under side of the parallel links. Such a rule is illustrated in Fig. 4.

Howard M. Ingham.

New York, N. Y.

At the annual meeting of the national advisory committee for aeronautics held recently, Dr. W. F. Durand, Mem.Am. Soc.M.E., was reelected chairman and Dr. S. W. Stratton, Mem.Am.Soc.M.E., was reelected secretary. Members of the executive committee were elected as follows: Dr. Joseph S. Ames, Dr. Charles F. Marvin, Dr. Michael I. Pupin, Major-General George O. Squier, U. S. A.; Dr. S. W. Stratton, Mem.Am.Soc.M.E.; Rear-Admiral D. W. Taylor, U. S. N., and Dr. Charles D. Walcott. At the organization meeting of the executive committee, Dr. Charles D. Walcott was elected chairman and Dr. S. W. Stratton, secretary.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

ANNUAL MEETING PROGRAM

New York, December 4 to 7, 1917

Tuesday, December 4

12.00 m. Opening of Registration Bureau in Engineering Societies Building

2.00 p.m. Council Meeting

8.30 p.m. Report of Tellers of Election and Introduction of the President-elect
Conferring of Honorary Membership upon Major-General George W. Goethals, followed by an address by Hon. William H. Taft
Reception by the President and the President-elect

Wednesday, December 5

9.45 a.m. Business Meeting, to be followed by the Keynote Session

It will be suggested to the Council that the Business Meeting be adjourned to Thursday morning to allow more time for the Keynote Session

10.00 a.m. Keynote Session on The Service of the Engineer to the Public in Times of Crises

Universal Public Service in Peace and War, Dr. Ira N. Hollis. This will be the presidential address by Dr. Hollis, after which there will be other addresses by distinguished men of national reputation on the following subjects relating to problems incident to the war: Agricultural problem; fuel problem; transportation; motor transportation; building of a merchant marine; aircraft problem; special education in time of war; engineering research. This will be an all-day session

12.30 p.m. Buffet Luncheon

2.00 p.m. Continuation of Keynote Session on The Service of the Engineer to the Public in Times of Crises

2.30 p.m. Simultaneous Sessions

POWER-PLANT SESSION

Preventable Waste of Coal in the United States, David Moffat Myers

The Cooling of Water for Power Plant Purposes, C. C. Thomas

Bagasse as a Source of Fuel, E. C. Freeland

The Steam Motor in the Automotive Field, E. T. Adams

GENERAL SESSION

The Transfer of Heat Between a Flowing Gas and a Containing Flue, Lawford H. Fry

A Study of Surface Resistance with Glass as the Transmission Medium, H. R. Hammond and C. W. Holmberg

Cooling and Drying Air and the Removing of Infinitesimal Dust Therefrom, W. J. Baldwin.

Recent Developments in Balancing Apparatus, N. W. Akimoff.

Plotting Blower-Test Curves, A. H. Anderson (*By title only.*)

Cross-Current Predeterminations from Crank-Effort Diagrams, Louis Illmer (*By title only.*)

INDUSTRIAL-SAFETY SESSION

Several codes will be presented for discussion by the Sub-Committee on Protection of Industrial Workers, among them Codes of Safety Standards for Elevators and Woodworking Machinery.

(*Continued on Next Page.*)

Wednesday, December 5 (*Continued*)

3.00 p.m. Ladies' Reception and Tea

8.15 p.m. Smoker

Get-together meeting for members. Mr. John R. Freeman, Past-President Am.Soc.M.E., will give an illustrated talk upon his trip to the Orient taken last winter with Dr. John A. Brashear and Mr. Ambrose Swasey, Past-Presidents Am.Soc.M.E. Music by Glee Club. Refreshments

Thursday, December 6

10.00 a.m. Business Meeting continued, followed by General Sessions

LOCAL-SECTIONS SESSION

This session will be held under the direction of the Sections Committee, for a discussion of the work of the Sections and of Society Affairs, by representatives of the 24 Sections of the Society

GENERAL SESSION

An Account of the Engineering Work of E. D. Leavitt, F. W. Dean

Expenses and Costs, H. L. Gantt

The following papers contributed by Local Sections will be presented by title:

By-Product Coke and Coking Operations, C. J. Ramsburg and F. W. Sperr, Jr.

The Submarine, C. H. Bedell

Combined Stresses, A. L. Jenkins

The Trumble Refining Process, N. W. Thompson

12.30 p.m. Luncheon, at which there will be an address on The Relation of Industrial Management to Engineering, by Prof. Dexter S. Kimball

2.30 p.m. Simultaneous Sessions

MACHINE-SHOP SESSION

Under the auspices of the Sub-Committee on Machine Shop Practice

Topical Discussion on the subject of Inspection with the following introductory discussions:

The Logic of Inspection, A. L. DeLeeuw

The Relation of Inspection to Product, F. A. Waldron

General Principles of Government Inspection and Relations Between Inspectors and Manufacturers, Col. B. W. Dunn

TEXTILE SESSION

Under the auspices of the Sub-Committee on Textiles

Labor-Turnover Records and the Labor Problem, Richard B. Gregg

Accident Prevention in the Textile Industry, David S. Beyer

The Moisture Content of Textiles and Some of its Effects, William D. Hartshorne

8.30 p.m. Lecture and Annual Reunion

The Beautiful in Commonplace Things, Dr. John A. Brashear. Following the lecture there will be a reunion and dance, with refreshments, on the fifth floor of the Engineering Societies Building

Friday, December 7

10.00 a.m. Simultaneous Sessions

MANAGEMENT SESSION

Topical discussion on the Employment of Women in the Skilled Industries, with particular reference to war conditions. To be introduced by Mr. John W. Upp, General Electric Co., and Mr. C. B. Lord, Wagner Electric Manufacturing Co.

The Engineer, the Cripple and the New Education, by Major Frank B. Gilbreth

POWER-TEST HEARING

A public hearing by the Power Test Committee, preliminary to a proposed revision of the Power Test Code of the Society, comprising rules for conducting tests on prime movers of different types, and auxiliary apparatus

2.00 p.m. Council Meeting

NOTE:—The above program was tentatively accepted at the meeting of the Committee on Meetings on October 26. It is possible that the arrangement of sessions may be modified slightly, but the program is issued in the present form to enable members and others to make their arrangements to attend the meeting. In the final program some of the features here announced will be augmented

COUNCIL NOTES

THE October meeting of the Council, the first meeting following the summer recess, was held on October 12 to enable President Hollis to attend before leaving for his visit to the Pacific Coast Sections. The following members were present: Ira N. Hollis, *President;* John H. Barr, C. H. Benjamin, Robert H. Fernald, Frederick R. Hutton, D. S. Jacobus, C. T. Main, C. T. Plunkett, John A. Stevens, and Calvin W. Rice, *Secretary.*

Executive Committee. Actions of the Executive Committee, taken on June 2, 21 and July 13, were made the basis of the following minutes:

It was voted to approve the appointment of the Committee on Coöperation and Organization, Mr. Fred J. Miller, *Chairman:* Messrs. L. P. Alford, Elmer H. Neff and F. A. Waldron.

Messrs. Victor J. Azbe, Bert L. Baldwin, T. J. Cookson, G. F. Gebhardt, J. J. Hoppes and F. E. Idell were approved as a Committee on Standardization of Feedwater Heaters.

Messrs. E. H. Ahara, G. M. Bartlett, C. H. Benjamin, J. R. Cantley, J. J. Flather, F. V. Hetzel and F. Morse were approved as a Committee on Standardization of Roller Chains.

Interpretations No. 153 to 161 of the Boiler Code Committee were approved.

Messrs. H. E. Harris, *Chairman;* John H. Barr, William A. Viall and L. A. Fischer were approved as a committee of this Society to develop a central bureau for the certification of gages and for the consideration of adequate facilities for certifying gages used throughout the United States in the manufacture and inspection of munitions of war.

Additional appropriations to the House Committee, Publication Committee and Committee on Engineering Resources, as recommended and approved by the Finance Committee, were approved.

Remission of Dues. The Committee on Constitution and By-Laws was requested to draw a by-law providing for the automatic remission of dues of a member reaching a certain age or having paid dues for a certain number of years.

Dues of Members in Military Service. The Secretary was requested to prepare a list of all members now in military service, to be published and distributed at the Annual Meeting.

It was the sense of the Council that such members should have their dues absolutely remitted for the period of the war and until six months after the declaration of peace.

Increase of Membership Committee. S. J. Hoexter was appointed chairman of the Michigan sub-committee, and C. R. Burt chairman of the Ontario, Canada, sub-committee.

Power Test Committee. It was voted to conduct a public hearing of the Power Test Code at the forthcoming Annual Meeting. Announcement of this hearing is given elsewhere in this issue.

An Advisory Committee was appointed to attend this and future hearings, and to confer with the Power Test Committee on request.

American Engineering Standards. The report of this committee was approved, and Messrs. Henry Hess, W. F. Kiesel and Carl Schwartz were appointed on the committee.

Engineering Council. The President reported on the present status of the work of this body and the call it would soon make for funds to carry on work principally for the Government in the present crisis.

American Institute of Architects. Mr. Clyde R. Place and Prof. J. W. Roe were approved to represent the Society as honorary vice-presidents in a conference with the American Institute of Architects' Committee on Quantity Production.

Machine Screw Nuts. Messrs. E. H. Ehrmann, E. Burdsall and Charles Glover were approved as a Committee on Machine Screw Nut Standardization, to coöperate with a similar committee of the Society of Automotive Engineers. Announcements regarding this joint committee have already appeared in THE JOURNAL.

Finance Committee. It was voted to approve and authorize the budget recommended by the Finance Committee of two hundred and five thousand five hundred and five dollars, with the understanding that this sum shall include an appropriation of five hundred dollars for the Standing Committee on Public Relations, and, further, the Finance Committee is authorized to make such adjustments within this appropriation as may be required during the year to meet the extraordinary demands upon the engineering societies occasioned by the war.

Second Liberty Loan. The Finance Committee was authorized to invest the sum of ten thousand dollars ($10,000) in the Second Liberty Loan.

Committee on Meetings. On recommendation of this committee, Messrs. W. W. Bird, *Chairman;* Stanley G. Flagg, Jr., B. D. Fuller, Robert E. Newcomb, Charles E. Knoeppel, Wilfred Lewis and Richard Moldenke were approved as a Sub-Committee on Foundry Practice.

Visits to the Sections. The President reported that in response to invitations from the Sections, he had arranged to visit St. Louis, El Paso, Los Angeles, San Francisco, Seattle and Portland. An account of Dr. Hollis's trip will be given in the next issue of THE JOURNAL.

Public Relations Committee. Mr. C. T. Main, member of this committee, reported its organization meeting on October 11, with Dr. F. H. Newell as chairman and Mr. Morris L. Cooke as secretary.

Constitution and By-Laws. Prof. F. R. Hutton, as chairman of this committee, presented a report of suggested new by-laws for the government of the local sections. This was adopted, and the By-Laws are published in this issue of THE JOURNAL under Sections.

Professor Hutton also reported suggested changes in the by-laws to meet the constitutional changes announced in the October issue of THE JOURNAL and to be voted on at the Annual Meeting.

Junior and Student Prizes. Recommendations of the committees on Award of Junior and Student Prizes were accepted, and the awards made will be announced at the Annual Meeting.

Committee on Sections. The organization of the Connecticut State Section was approved, with headquarters at New Haven and branches at Meriden, Bridgeport, Hartford and Waterbury.

Mr. W. L. Roueche was appointed secretary-treasurer of the Birmingham Section.

Adjournment was taken to meet in Chicago on November 16.

CALVIN W. RICE,
Secretary.

Those members who have not yet received Vol. 38 of TRANSACTIONS are notified that the delay has been caused by embargos on freight shipments to some points.

ROLL OF HONOR

In the May issue of The Journal we published the first list of members of the Society who have enlisted in the service of the country in its great drive "to make the world safe for democracy," and it is interesting to note the rapid growth of the Honor Roll. We have published notices of 566 members from all parts of the Union who have notified us of their enlistment. A large proportion of members listed are commissioned in the Engineer Officers' Reserve Corps or in the Ordnance Department, Officers' Reserve Corps. The Aviation Section of the Signal Corps, and the Naval Reserve, are also well represented.

If any members have joined the armed forces of the country, but have so far not been listed in the Roll of Honor, they are invited to send in their names to the Secretary. The Society is proud of their action and is anxious to apprise their fellow members of it. Further, the Society would be pleased to publish, and members at home would be interested to read, "experience letters" from men who are out on active service.

The following Roll of Honor supplements those already published:

Adams, C. F., 103rd Regiment Field Artillery, 26th Division American Expeditionary Forces.
Allen, Jared E., First Lieutenant, 26th Engineer Regiment, Camp Dix, N. J.
Ames, John H., First Lieutenant, Ordnance Department, U. S. R.

Baird, Lyman S., First Lieutenant, Aviation Section, Officers' Reserve Signal Corps.
Bakker, George S., First Lieutenant, Ordnance Department, U. S. A.
Bates, Harry H., Officers' Training Camp, Ft. Myer, Va.
Besse, E. E., First Lieutenant, Ordnance Department, Officers' Reserve Corps.
Bond, F. M., Captain, Inspector of Ordnance, St. Louis, Mo.
Boyd, Hugh M., Second Lieutenant, F. A. O. R. C., Camp Upton, L. I.
Boyer, Fred. O., First Lieutenant, Second U. S. Engineers.
Brennan, E. M., First Lieutenant, 309th Engineers, Camp Taylor, Louisville, Ky.
Brown, Eugene L., Jr., First Lieutenant, Engineer Officers' Reserve Corps.
Brown, Fred W., Captain, Ordnance Department, Officers' Reserve Corps.
Burton, W. Dean, Aeronautical Mechanical Engineer, U. S. Signal Service, Fort Omaha, Neb.

Campbell, E. D., Captain, Ordnance Department, Carriage Division, Washington, D. C.
Cassidy, Perry R., Captain, Coast Artillery, Officers' Reserve Corps.
Chamberlain, Paul M., Ordnance Section, Officers' Reserve Corps.
Christen, A. B., First Lieutenant, Signal Corps.

Dallis, Park A., Engineers' Training Camp, Atlanta, Ga.

Eichenberg, M. A., Inspector of Aeroplanes and Aeroplane Engines, United States Signal Corps.
Ellsworth, Perry F., First Lieutenant, Signal Corps, U. S. R.

Farr, Roy S., Second Lieutenant, Co. 1, Engineer Reserve Officers' Training Camp, American University, Washington, D. C.
Felker, George F., Captain, Ordnance Department, U. S. R., Camp Wheeler, Macon, Ga.
Fowler, W. S., First Lieutenant, Ordnance Department, Carriage Division, U. S. R.

Gaillard, D. P., First Lieutenant, Ordnance Officers' Reserve Corps, Division T, U. S. A.
Gfrorer, Albert H., First Lieutenant, Officers' Reserve Corps, Ordnance Department.
Gilbreth, Frank B., Major, Ordnance Department, U. S. A.
Gilman, F. W., First Lieutenant, Engineer Officers' Reserve Corps, Reserve Officers' Training Camp, Ft. Myer, Va.
Githens, Thos. F., Plattsburg Training Camp.

Glenn, E. R., Officers' Training Camp, U. S. A., Oglethorpe, Ga.
Goltzberger, R. L., First Lieutenant, Ordnance Department, U. S. R., American Expeditionary Forces.
Gregory, W. B., Major, Engineer Officers' Reserve Corps, American Expeditionary Force.
Geise, H. B., Major, Ordnance Department, Officers' Reserve Corps.
Gutierras, J. G., Lieutenant, 4th Engineers, Vancouver Barracks, Wash.
Guthrie, James, Major, Ordnance Department, Officers' Reserve Corps, U. S. A.

Hale, Henry A., Jr., Captain, Engineer Officers' Reserve Corps.
Hall, Keppele, Captain, Ordnance Department, U. S. R.
Hall, Quincy A., Captain, Engineers' Section, Officers' Reserve Corps.
Harries, George H., Major General, Headquarters 59th Depot Brigade, Camp Cody, Deming, N. M.
Hewitt, R. B., Captain, Engineers' Department, Fort Sam Houston, Texas.
Hirsch, Gustav, Major Signal Corps, U. S. R.
Holman, R. C., Captain, I. O. M. O. C., 53rd Ordnance Mobile Workshop (Light), British Expeditionary Forces, France.
Hurxthal, A. O., First Lieutenant, Ordnance Department, Officers' Reserve Corps, U. S. A.

Jurgensen, J. C., Major, Ordnance Department.

Kaelin, Charles G., Captain, Ordnance Department, U. S. R., Frankford Arsenal, Bridesburg, Pa.
Kaley, George B., First Lieutenant, Ordnance Department, Officers' Reserve Corps, U. S. A.
Kent, Edward R., Officers' Training Camp, Ft. Myer, Va.
Kilpatrick, John D., Major, National Guard, N. J.

Lacombe, C. F., Captain, Engineer Officers' Reserve Corps, U. S. A.
Larsen, Charles, Captain, 26th Engineers, Camp Dix, N. J.
Le Fevre, C. D., Ordnance Officers' Reserve Corps.
Lipsner, B. B., Captain, Ordnance Department, Motor Section, U. S. A.
Longley, Francis B., Major, Engineering Department, Signal Corps Aviation School, San Diego, Cal.
Longstreth, Charles, Lieut. Commander, U. S. Naval Reserve Force.
Lord, Harold S., First Lieutenant, Engineers, U. S. R.

MacMaster, R. K., First Lieutenant, Engineer Corps.
Mallory, Chas. K., Lieutenant, U. S. N., Bureau of Steam Engineering, Washington, D. C.
Mann, Carl P., Officers' Training Camp, Ft. Myer, Va.
May, O. J., Captain, Engineers' Division, U. S. A.
Metz, W. R., Captain, Quartermaster Corps, U. S. R.
Meixner, Bernard A., First Lieutenant, Ordnance Department, Officers' Reserve Corps.
Mickle, Frank A., First Lieutenant, Ordnance Department, Officers' Reserve Corps.
Middleton, Nathan A., Captain, Engineer Officers' Reserve Corps, U. S. A.
Miller, Philip F., First Lieutenant, Field Artillery Section, Carriage Division, Ordnance Department, U. S. R.
Misch, Arthur A., First Lieutenant, Ordnance Section, Officers' Reserve Corps, U. S. A.
Myers, J. L., First Lieutenant, Ordnance Department, Officers' Reserve Corps.

Nigh, G. W., Camp Funston, Fort Riley, Kan.
Norris, Earle B., Captain, Ordnance Officers' Reserve Corps, Field Artillery Section, Carriage Division, Ordnance Department.

Pratt, Prof. Joseph Hyde, Major, Engineers, Separate Battalion, N. C.

Rathjens, G. W., Major, 313th Engineers, Camp Dodge, Des Moines, Iowa.
Richardson, Edward B., Major, American Expeditionary Forces, France.

Short, Frank, First Lieutenant, Ordnance Department, U. S. A.
Smith, Horace L., First Lieutenant, 1st Regiment of Engineers, France.
Stark, W. E., Lieutenant, Company C, 5th Engineers, Corpus Christi, Tex.
Stepanek, Emil, Battery B, 333rd Field Artillery, Camp Grant, Ill.
Stetson, John B., Jr., Aviation Section, U. S. A.
Streeter, Robert L., Captain, Ordnance Department, U. S. R.
Summers, Daniel, First Lieutenant, Engineer Officers' Reserve Corps, Camp Meade, Md.

---

* Acceptance of commission pending at date of latest list from War Department.

SWAIN, P. W., Second Lieutenant, Field Artillery, Camp Devens, Mass.
SWIFT, HARLEY L., First Lieutenant, 16th Regiment Engineers, Engineer Officers' Reserve Corps.
SWETTING, J. R., Second Lieutenant, Engineer Officers' Reserve Corps.

TALBOT, J. A., Second Lieutenant, Field Artillery Section, Officers' Reserve Corps.
THOMPSON, P. W., First Lieutenant, Inspector of Ordnance, Ordnance Department, U. S. R.
TILSON, HOWARD, Ordnance Department, Officers' Reserve Corps.
TROWBRIDGE, AMASA, Major, Ordnance Department, Officers' Reserve Corps.

VINNEDGE, EARLE W., Second Lieutenant, 309th Engineers, Camp Taylor, Louisville, Ky.

WALKER, L. E., First Lieutenant, Ordnance Officers' Reserve Corps, Carriage Division
WEBSTER, LAWRENCE B., Captain, Ordnance Department, U. S. A.
WELLING, LINDSAY H., Ordnance Department, Rock Island Arsenal, Rock Island, Ill.
WIELAND, C. F., Captain, Officers' Reserve Corps, U. S. A.
WILLIAMS, S. S., Signal Service, U. S. A., Atlanta, Ga.
WOODBURY, J. G., Major, Ordnance Department, U. S. R.
WRIGHT, DOUGLASS B., Second Lieutenant, Engineer Officers' Reserve Corps, United States Expeditionary Forces, France.

ZEIGER, N. A., First Lieutenant, Ordnance Department, U. S. R.

Secretary's Letter

Have you subscribed for a Liberty Bond? If not, won't you please immediately telephone your bank offering to take a bond if not too late, or to subscribe to the next issue? Also arrange to pay for it out of future savings, not by selling investments or withdrawing moneys in savings banks,—both of which are required to continue, without embarrassment, the existing industrial conditions.

Then won't you take up the matter in your business relations? Get everybody saving and investing their savings in Liberty Bonds. Every member of your department should take a bond; if not, know why.

Only ten per cent of the face of a bond need be paid in. The bank will carry the balance at four per cent, the same as the Government pays. If your bank is unwilling to do this, notify me and I will advise you of a bank that will. Business is done on credit. The Government needs the credit of the people. Why not lend your credit to your Government?

Are you aware that to win this war, 10,000,000 people must subscribe for bonds, and that only by the combined energies of every man, woman and child we can win? If you can, take out a bond for every member of your family and instruct them to help pay for it out of sacrifices, candy, entertainments, clothing, everything that is unnecessary. Don't fear that you are going to put people out of employment if every one stops waste. The United States is starting on a rate of production that is going to require the labor of 10,000,000 people on war activities alone!

I know of factories going up where there are all manner of machine tools, lathes, planers, boring machines, etc., and not only now is every employee a woman, but no men are to be employed because there is no prospect that there will be any men for an indefinite period.

Come to the Annual Meeting and hear all about the employment of women in the industries and how the several problems have been met.

Every feature of our Annual Meeting is of vital interest to you. Learn how you can be of greater service to your country in this crisis. It is your duty to your profession to have it render the greatest service to the nation.

CALVIN W. RICE,
Secretary.

A.S.M.E. Standards

SOON after its foundation in 1880, the Society instituted the procedure of creating standards of method and dimensional standards and of issuing such standards in printed form for general use. To date upward of fifty such standards, or codes, have been formulated, and some of them have been widely adopted and have become the basis of extensive manufactures.

The consideration of a proposed standard by the Society has usually been inaugurated as the result of its attention being called to diversities of proportions existing in similar pieces produced by different manufacturers; variances in methods of measurement of similar quantities; lack of a uniform basis of expression of certain facts; absence of interchangeability, etc.

Sometimes the absence of the standard, and the consequent necessity of it, has been pointed out by a competent authority in a paper embodying a resolution recommending the expediency of the Society considering the matter and reporting. Sometimes an interested party has addressed the Society requesting an opinion, which has later been made the basis of a standard. Sometimes the Society itself has recognized the necessity for a uniform procedure and has taken the initial step toward its creation.

In all cases, upon affirmative action by the Council of the Society, accepting the duty to formulate the standard, a committee of competent persons, members of the Society and other authorities, has been appointed to frame recommendations. Such committees have always been charged to take into their confidence all interested parties and to submit their findings to such parties for inspection and criticism before reporting them to the Society.

Reports of standards committees are presented at a general meeting of the Society and are, upon presentation, open for discussion by the whole membership and by others interested. Following such discussion, if, by vote, the recommendations still stand, the report is referred to the Council, who receive it and, upon approval by them, order it entered upon the record and printed in the TRANSACTIONS of the Society.

In cases where the field of action covered by a committee is very wide, viz., such as that of the Boiler Code Committee or the Power Test Committee, it has become the practice, on the acceptance of the committee's report and its subsequent discharge, to appoint a permanent committee to interpret the rules when called upon to do so, to make such revisions as may be found desirable, and to modify the rules to meet such new conditions as arise. These interpretations and rules are formally approved at meetings of the permanent committee, and by letter ballot submitted to the members who could not attend the meeting. They are thereupon submitted to the Council, and if approved printed in THE JOURNAL. The permanent committee holds meetings from time to time, at which all interested parties are given an opportunity to present suggestions with regard to the standards under consideration. These meetings constitute "revision periods" and take place at stated intervals, for instance, once in two or more years. All revisions of the codes or standards involving a change of meaning are reserved for these meetings, which may also take the character of "public hearings" so as to afford everybody interested an opportunity of stating his case in public.

Recent developments in the standardization work of the Society include the appointment, by amendment to the Constitution in the Spring of 1915, of the Standardization Committee as a standing committee of the Society. It is the function of this committee to standardize the method of making

and arriving at standards rather than create standards themselves. This committee endeavors to bring about a unification of the standardizing work of the Society, and for this purpose national and international coöperation between organizations and governments, including an exchange of information with regard to standardization.

Finally there is the Standardization Committee of the national engineering societies to coöperate by representation on a proposed Joint Committee composed of three representatives each from the national engineering societies, to consider and report back to their respective societies suggested means of bringing about coöperation in the formulation of American Engineering Standards.

The Society is at all times prepared to formulate standards within its field of activity and to assist other organizations in the preparation of standards, and will, upon request, appoint members to serve on committees for this purpose. Several such coöperative committees are at work at the present time.

It should be reiterated that none of the reports are adopted by the Society. They are simply actions which carry weight and a recommendation, but no further obligation. In practically all cases the standards have been accepted by outside parties, but of course without request by the Society.

Catskill Aqueduct Celebration by Engineers

The completion of the Catskill Aqueduct is an event of such extraordinary engineering importance that, notwithstanding the war, the citizens of New York decided that it should not pass unobserved. As an engineering feat, the aqueduct is the greatest accomplishment of its kind in history and a monument to American genius.

THE CATSKILL AQUEDUCT MEDAL

To plan and carry out the arrangements for the commemoration, the Mayor of New York, Hon. John Purroy Mitchel, appointed a Mayor's Catskill Aqueduct Celebration Committee, with Hon. George McAneny as chairman and with various sub-committees. The Sub-Committee on Art, Scientific and Historical Exhibitions, Dr. George F. Kunz, chairman, in turn invited the United Engineering Society to appoint a committee to coöperate with it in planning the engineering features of the celebration. This committee consists of Messrs. Samuel Sheldon, Chairman; Charles Warren Hunt, Calvin W. Rice and E. Gybbon Spilsbury.

The celebration commenced on October 12 with appropriate exercises, such as turning on the Catskill water at new fountains in City Hall and Central Parks; emptying the lower Croton reservoir, now to be abandoned; civic parade; exercises in the public schools and exhibitions by the historical, scientific and art societies.

The United Engineering Societies Committee, working with Dr. Kunz's sub-committee, has planned an Aqueduct Celebration by engineers to be held in the Engineering Societies Building, New York City, on November 14. Mr. George H. Pegram, President of the American Society of Civil Engineers, will preside, and there will be addresses by Hon. John Purroy Mitchel and Major-General George W. Goethals. Mr. A. D. Flinn, deputy chief engineer of the Metropolitan Board of Water Supply, will deliver an illustrated lecture on the Catskill Aqueduct.

Power Test Hearing

A public hearing of the Rules for Conducting Tests of Power Plant Apparatus (Power Test Code of 1915) will be held in the Engineering Societies Building, New York, December 7, in connection with the Annual Meeting. The hearing will be conducted by the Power Test Committee, and the Advisory Committee of this Committee will attend.

Condensed Catalogues

The Seventh Annual Volume of the A.S.M.E. Condensed Catalogues is the largest and most comprehensive edition of this book yet published. An endeavor has been made in the new volume to increase the value of this publication to the membership and to the mechanical profession at large. Many more firms than ever before are represented by publication of their data in the Catalogue Section.

The general Mechanical Equipment Directory, which was inaugurated as a new and distinctive feature in the 1916 volume, appears in this edition in enlarged and improved form. In its preparation the suggestions received from members and others, following the initial appearance of the Directory in the issue for last year, have been of much assistance. During the past year the Society's records relating to manufacturers of mechanical equipment have also been extended, with the result that in this edition the Directory contains the names and addresses of more than 3200 different firms, indexed and cross-indexed under upward of 2500 subject headings.

The section of Engineering Data has also been extended and improved in this volume. In addition to the data selected from THE JOURNAL and TRANSACTIONS for the past year, a summary of the work of the standards committees of the Society is included this year.

PRESIDENT HOLLIS ADDRESSES THE CLEVELAND ENGINEERING SOCIETY

On September 11, Dr. Ira N. Hollis, President of The Am.Soc.M.E., addressed the Cleveland Engineering Society on the subject of Engineering and Coöperation, in which he urged most earnestly that the engineers of the country come together for those interests which they hold in common. He expressed the hope that the Engineering Council would soon become representative of every engineering society in this country, local as well as national, making the council a body of men, in number between sixty and seventy, who can truly speak for the engineers of the country, and having power delegated to them to speak. Dr. Hollis said in part:

ENGINEERING AND COÖPERATION

How can coöperation be applied to engineers in a special way so that they can be more able to serve the colors or to dedicate themselves to real service? How can the engineers best work together? We call this an age of specialization in connection with engineering and everything else; but what is specialization but coöperation?

There are various methods by which coöperation may be brought about, and I care not how it is brought about, whether through national engineering societies, local engineering societies, engineering clubs, or through colleges, so long as it is effective.

In the national societies we have made an effort during the past few years, by means of sections of the societies in various parts of the country, to interest groups of our men in what the national bodies want to do. The American Society of Mechanical Engineers, for example, has sections in a great many of the large cities all the way to California. That does not mean that the parent society is unfriendly to local societies. I have often said, in fact, I always say in a city like this, we desire every engineer to belong to one of the national societies, and, above all else, to his local society of engineers.

We have made many efforts to bring the societies together into what might be called a great national society, and they have always been failures. They have appeared in the form often of conference committees representing a number of societies.

We have had special conferences on all kinds of subjects, started for the purpose of elucidating some one subject in which all of the engineers are interested. I recently proposed in a letter to the chief engineering societies, the constituting of a council that would last for all time and recognize this condition of certain things common to all engineers as apart from the technical matters we want to study and work out in our own societies. The idea was threshed out for three or four months, and I thought it was going to fail. It did not, however, and we have now in the Engineering Council at least an attempt to solve questions among civil, mechanical, electrical and mining engineers of this country.

What are the kinds of questions common to engineers? The American Society of Mechanical Engineers was founded, and in the ideas of its founders was constituted, for the education of its members in technical matters by the interchange of papers, by reading papers for one another's education, and we have profited by that. It is truly an educational institution. Now, out of that society there have grown, as the result of experience, certain needs for a better understanding of the relation of that society to the public. The reading of a technical paper is a very good thing, but if we do nothing else than listen to technical papers and meet only to exchange views about machinery, we are narrowing our viewpoints a good deal, and depriving the members of our society of the opportunity to become really enlightened in the application of their profession to the great needs of society.

The way to solve our problem of coöperation in the United States amongst the engineers is not by establishing a new society for that purpose, but by making use of the agencies that already exist—all the national and local engineering societies.

It seemed to me that we might have a congress of engineers. I asked a year ago if it was not possible to take the four national societies that are rather concrete and within reach, so that getting them together would be practical at least, and see if we could not have one meeting, where all of us met. I have sometimes thought that it would be a good thing if we could extend this idea to the whole of the United States, and have one grand roundup at some place in this country where we could all get together and perhaps spend a week in threshing out one another's full ideas and bringing something out of the discussion that would be worth while. I have despaired of being able to carry out this plan through pressure of other work. I do not know of any other way to do it than to bring the societies face to face from month to month with the numerous problems that are common to them all, and that is what we propose to do through the medium of the Engineering Council.

My hope for the Engineering Council is that it is simply the beginning of a council backed by the engineering societies themselves, having power delegated to them to solve certain questions without any reference back to the societies at all, as engineers, and my hope is that every engineering society in this country, local as well as national, will in the course of a few years belong to the Council, making it a body of men, in number between sixty and seventy, who can truly speak for the engineers of the country, and having power delegated to them to speak.

To my mind, I think we have in the Council the greatest opportunity the engineers have ever had in the history of this country for all of us to get together. All of us ought to go to work to help it and strengthen it in every way, and if it does not broaden itself out so that other societies become members of it and have their voice—their voices are just the same as those of the men who are working in the Engineering Societies Building in New York—it should be made to.

I do not know of any better way, to begin with what I call real coöperation, than to take the agency which has gradually grown out of a necessity in New York City, and strengthen it into a truly national council that represents you engineers in Cleveland just as much as it represents the men in New York or the men in any other place.

In connection with the extension of representation on the Engineering Council, I appointed a committee, each of whose members represents seven or eight societies, for the purpose of seeing what can be done toward compiling a complete directory of all the engineers of the country. There are four types of engineers so far as their relation to the societies is concerned: those who belong to one or more national societies, those who belong to a local society and a national society, those who belong to a local society and do not belong to a national society, and those who belong to no society at all. All ought to come in our listing as part of the public service that the societies can do for the engineers. I think the directory, if compiled, ought to be in two places, one in the Engineering Societies Building in New York, being a complete list, and the other a local list for use in every locality; so that there are two places where we ought to have such a list, one that applies to Cleveland, we will say, and one that applies to the whole nation.

This committee has been putting in no end of time and study. For the purpose of the war they have already made out a first-class list of fifteen hundred or two thousand men who have intimate knowledge and great experience in specialties. That list is used by the United States Government; in fact, hardly a day goes by that we do not have some request in connection with it. But there is the after-war condition, where such a committee representing all the engineers could be of great use in connection with the readjustment of our industries.

We know as engineers why we ought to work together. There is, however, a last thought I want to put into your minds, that we gather strength just in proportion as we impress upon the other citizens of this country that we belong to a truly great profession interested in the welfare of this country. I sat down in Washington the other day to listen to Mr. Post, assistant to the Secretary of Labor, and other gentlemen speak on the establishment of what they call a public-service reserve, which would naturally belong to the army or navy. Mr. Post gave me a list of the positions that he proposed to fill, including plumbers, boilermakers, blacksmiths, all down through all the trades. I said to him, "Why, Mr. Post, you misunderstood the situation; you must be thinking of engine drivers." "Oh, no," he said, "I am thinking of the engineer." "Well, but," I said, "the engineers

are professional men?" "Oh, no," he replied, "they are wage earners." Now, that was a description that is totally false. We are wage earners in the sense that the lawyer and the doctor is a wage earner, but we are not wage earners in the sense that a man who goes to work ten hours a day for so much an hour is. We may have to go through that apprenticeship, and it is a good thing to go through it, but nevertheless when we talk of engineering we mean the profession involving the same amount of thought, the same interest in the development of our country that the lawyer or the doctor has.

Consequently, I emphasize the word *profession*, and I believe that in coming together as engineers (not necessarily in one great engineering society, which I think is a piece of Utopian foolishness) our national and local societies can cultivate the vocation peculiar to themselves just as well after they come together as they do now, and to come together for those things common to all and that relate to the public relations of the engineering societies. Do not let us surrender the fact that we are professional men, that whether we get our education in college, or whether we get it by the hard knocks of experience, we have learned a great profession without which our country would be an undeveloped and barren waste.

WAR ACTIVITIES OF TECHNICAL SOCIETIES

By CALVIN W. RICE, NEW YORK

Secretary, The American Society of Mechanical Engineers

WAR is a science; in fact, it is one of the most complex of sciences. This has been recognized for ages, but in the present war it has become particularly evident. War in the air, war under the sea, war by means of novel surface machines, bombs and gases have all added to the complexity of the science.

War has become a matter of complete military and economic organization, into which every man, woman and child must be massed. The sole thought and effort of the nation in modern war must be concentrated on the business of making war. Particularly is this true in "our" war.

In this complete organization the technical men play not a small part, and it is, therefore, but natural that the several technical societies representing them should be active as such in the war period. It is, however, with no thought of taking peculiar credit that the following activities of the technical organizations are enumerated—it is realized that at this time the nation places dependence on everyone, no matter what his talent or connections.

It was during the Civil War in 1863 that the National Academy of Sciences was formed and Congress gave it a charter to advise the Government in all technical matters. Therefore, it was to be expected that with the war problems accumulating, as they did last year, the Academy should again offer its services, and the President of the United States officially received them in September, 1916. President Wilson invited the President of the Academy at that time to form what is known as the National Research Council. The Council has functioned continuously since its appointment and has performed excellent service.

The Council is a body of about 40 men, members of technical societies, who have in turn arranged themselves into numerous committees to study all realms of research. The following is part of a statement kindly prepared by the Vice-Chairman of the work of the Council to date, condensed with difficulty on account of the great variety and scope of its activities:

BROAD WORK OF THE NATIONAL RESEARCH COUNCIL

All of the work of the National Research Council that touches upon Army and Navy problems is carried on with the advice, coöperation or control, as the case may be, of the representatives of the various Departments of the Army or Navy under which such work comes.

The Council has coöperated in the establishment and organization of the submarine experimental work at Nahant, Mass., and has also established a very active submarine station at New London, Conn., and another at San Pedro, Cal., and has been instrumental in the organization of groups working at New York, Chicago and Madison, Wis. There has resulted a great practical advance in the art of submarine detection which it is not desirable to go into further.

The Physics Committee of the council has distributed to various groups twenty or more large problems in physics, which are being actively worked upon and some of which have already been solved. Among the latter are the location of aircraft by sound, the development of fire control for anti-aircraft guns, telephoning between aeroplanes, protection of balloons from ignition by static charges, and development of new and improved methods of measuring muzzle velocities.

The Chief Officer of the Signal Corps of the Army has asked the National Research Council to act as the Division of Science and Research of the Signal Corps, and in this capacity the Council has organized a sound-ranging service in the Signal Corps, and a new meteorological service in the same corps, and is now drawing specifications for scientific instruments to be used on aeroplanes. It has sent a dozen of the best physicists in the country to France to aid the American Expeditionary Forces with their scientific knowledge, and is selecting a personnel of several hundred men who are to be engaged in the scientific services of the Army and Navy.

The Chemistry Committee has perfected an elaborate organization for handling all the chemical problems which arise in the Army and Navy, and it has distributed some 150 chemical problems which are being attacked in the chemical laboratories of the country.

The Engineering Committee has contributed in no small degree to the development of devices for the protection of ships from submarines. It has organized a large group which is now working on the development of steel protective devices for use of the soldiers at the front. Through coöperation with the National Advisory Committee for Aeronautics it has carried on extensive and important researches in the development of aeroplanes and aeroplane engines.

The Nitrate Committee has made an elaborate study and report which has been made the basis for the expenditure by the Government of large sums of money upon the erection of a nitrate plant and upon kindred projects.

The Gas Warfare Committee has had for six months 120 chemists working on the problems of gas warfare, and the results already obtained have been of the utmost importance—so important that the Army and Navy have placed large appropriations at the disposal of this committee for its researches.

The Optical Glass Committee, by taking from research laboratories like the Geophysical Laboratory a dozen or more silicate chemists and putting them directly in the works of the Bausch and Lomb Company and the Pittsburgh Plate Glass Company, has in six months' time developed in America the production of optical glass from nothing up to 20,000 lb. a month, and in two months more this figure will have been multiplied two or threefold.

The Foreign Service Committee, which the Council sent abroad at once upon the outbreak of the war, was wholly responsible for the sending back to this country of French, English and Italian Scientific Missions, which brought with them the contributions which science had made to the war, both in the matter of instruments and methods, and unquestionably saved months of time in putting the United States abreast of the European situation, as regards modern scientific methods in warfare. It is difficult to overestimate the stimulus to American participation in the war which resulted directly from the action of the National Research Council in sending abroad at once this Foreign Service Committee composed of seven of the best scientists in the country.

Abstract of address before the Southern Commercial Congress, New York, October 15, 1917. The author wishes to acknowledge his indebtedness to Mr. W. E. Bullock, Associate Editor of THE JOURNAL, for his assistance in the preparation of this paper.

THE ENGINEERING FOUNDATION DONATES ITS INCOME

Just previous to the declaration of war by the United States, the American Society of Civil Engineers, The American Society of Mechanical Engineers, the American Institute of Mining Engineers and the American Institute of Electrical Engineers were developing coöperative relations with the National Academy of Sciences through the Engineering Foundation, this latter being a group of men representing the above societies in the administration of funds devoted to the service of man through the instrumentality of the Engineer. The Foundation promptly placed its financial resources and staff at the disposal of the National Research Council, and these services have been continued until recently, when subventions have been received by the National Research Council sufficient to enable it to maintain independently the many and heavy demands which were fast exceeding the resources of the Foundation.

THE NAVAL CONSULTING BOARD EXAMINES 200 INVENTIONS A DAY

In the preceding fall, in October, 1915, the Secretary of the Navy invited twelve engineering and technical societies to nominate two men each whom he might appoint on the Naval Consulting Board. The societies responding were the four previously mentioned and the American Chemical Society, American Mathematical Society, American Aeronautical Society, Inventor's Guild, Society of Automotive Engineers, American Society of Aeronautical Engineering, American Institute of Metals and the American Electrochemical Society.

You are all familiar with the great industrial census directed by the Committee on Industrial Preparedness, a sub-committee of the Naval Consulting Board, whereby all industries in the United States doing an annual business in excess of $100,000 were listed, together with all pertinent information as to their capacity, number of workmen, location with respect to sources of materials, transportation, etc. These data have all been collated on cards similar to those used in the United States Census.

Committees in each of the forty-eight states, the territories, and the District of Columbia were formed by the following five Societies: American Society of Civil Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers, American Institute of Electrical Engineers and the American Chemical Society, who performed the work, assisted, of course, by the companies themselves. Much if not all the undertaking was without expense to the Government.

A first essential to all work to be done by the people generally must be publicity. To explain and popularize this census the President of the United States wrote a letter inviting the above five societies to undertake the work and the Associated Advertising Clubs of the World raised donations approaching one million dollars of advertising space throughout the press of the United States to display the President's letter and explain the census.

In the matter of inventions alone the Naval Consulting Board is receiving in excess of two hundred propositions a day which require for disposition the continuous voluntary services of a large number of the members of the technical societies.

THE SOCIETIES' INFLUENCE ON WAR LEGISLATION

All these voluntary activities of the people of the nation were consummated in the establishment of the H. R. Bill 16,460, in July 1916, of the Council of National Defense composed of six members of the Cabinet and Advisory Commission of seven civilians.

The Advisory Commission has numerous committees with which the public is now familiar. The principal ones, however, of War Industries and Air Craft, are headed by men originally designated by the technical societies as their representatives in some war work.

The constant aim of all has been to uphold and strengthen the regular departments of the Government and enable them to meet the demands which have taxed them to the utmost.

The four engineering societies already mentioned as taking the industrial census, joined by the American Institute of Consulting Engineers, were active in the movement which resulted in the legislation providing for the Engineer Officers' Reserve.

The nation has by this legislation obtained and placed in military relation the services of thousands of the best men of the profession and augmented the staffs of every bureau of the Government.

THE SOCIETIES AND MILITARY EDUCATION

Very early in the war, and sensitive to the needs of the national engineering societies, the Engineers' Club of New York formed a military engineering committee. The object of this committee was both to arouse the people to the necessity of preparedness and to instruct them in military tactics. The engineers in New York were duly prominent in the preparedness parade, which was the forerunner of similar parades all over the United States.

A series of military lectures was given in the Engineering Societies Building under the auspices of the committee. The lecturers were mainly men loaned by the War Department, but credit is due them for faithfully giving this course lasting several weeks when it is understood that the preparation and giving of the lectures was in addition to and outside of the strenuous work of an army officer preparing for war.

The same committee later supervised and financed the recruiting of a division of engineers for France.

SPLENDID WORK OF THE S.A.E.

No one Society has had a more prominent or important part in war work than the Society of Automotive Engineers. It has not only furnished some of the most valuable volunteer men now in the departments of the Council of National Defense, but as a strictly technical work the Society has undertaken standardization of air-craft production, maintaining a suite of offices and a staff both in New York and in Washington.

The engineers who designed the wonderful Liberty Motor are members of the Society of Automotive Engineers.

The Society is also prominently represented on the Automotive Transport Section of the War Industries Board.

The American Railway Association, coöperating with the Chairman of the Advisory Committee of the National Council of Defense, has a Committee on Transportation consisting of 28 railway executives.

THE AMERICAN MUSEUM OF SAFETY'S CONTRIBUTION

The American Museum of Safety has been coöperating with the Government to conserve the lives and health of workers in federal industries. It undertook a safety survey of federal plants, the director of the Museum being placed in charge of safety inspection work. As the result of this survey the Government placed an experienced safety engineer in each navy yard and arsenal, and a central safety committee has been organized in Washington for directing the Government's accident-prevention work.

The director of the Museum has been appointed chief safety expert of United States Employees' Compensation Commission. The trustees have released the director of the Museum to serve without cost to the Government as advisory safety engineer. Two of the thirteen safety engineers appointed by U. S. Employees' Compensation Commission were selected from the staff of the Museum.

ACTIVITIES OF THE CHEMISTS

The American Chemical Society, in addition to participation in the Research Council and the Naval Consulting Board, has coöperated with the American Institute of Mining Engineers and the U. S. Bureau of Mines in the preparation of a census of chemists, metallurgists and mining engineers, for which there is a great demand.

The society was prominent in the movement to protect the needs of the Government for scientific and industrial work in the matter of platinum supplies.

The society has coöperated in the selective draft, in similar manner to that previously mentioned in connection with the Society for the Promotion of Engineering Education, and arranged that drafted chemists shall be assigned to their special work, for which the Government is in great need.

THE ENGINEERING COUNCIL APPOINTS WAR COMMITTEES

The Engineering Council, representing the Civil Engineers, Mining Engineers, Mechanical Engineers and Electrical Engineers, has a War Committee of Technical Societies and also the American Engineering Service Committee.

The latter has collected already the classification data of several thousand professional engineers and is continually extending its files and eventually plans to have catalogued 110,000 professional engineers and technical men.

Its committee for months has been supplying all departments of the Government and the industries generally with the names of engineers of specialties in all lines. The service is entirely free. Any department of the Government or any industry needing professional engineers may apply at the Engineering Societies [illegible], 29 W. Thirty-ninth Street, New York, and service will be rendered [illegible].

THE SOCIETIES AND GOVERNMENT STANDARDS

In addition to the coöperation in the joint activities already mentioned, The American Society of Mechanical Engineers has committees coöperating with the Government in the matter of certification of gages, in an effort to ensure uniform production throughout the United States. The working out of the idea which is so obvious to all will nevertheless demand the greatest coöperation on the part of everyone.

The American Engineering Standards Committee, representative of several of the societies already mentioned, is assisting in an international as well as national service of standardization of all kinds, both for the period of the war and afterwards.

THE VARIED BUT VITAL ACTIVITIES OF THE SOCIETIES

The American Railway Engineers' Association has published and distributed a manual of recommended practice to all the members of the railway regiments in France.

The National Machine Tool Builders' Association has coöperated with the Council of National Defense, the Air-Craft Production Board and in the production of the new Liberty Motor. A comprehensive list of all the machine tools in the United States ready for delivery was prepared and furnished the Government.

The National Electric Light Association, The Association of Edison Illuminating Companies, The American Gas Institute, assisted also by the American Water Works Association, the Illuminating Engineering Society and the American Society of Refrigerating Engineers have for months maintained an office and staff in Washington and have undertaken a comprehensive service for gas and electricity to the various cantonments regardless of commercial considerations on the one hand, and on the other have been the clearing house to assist municipalities and aid utility companies to secure the coal necessary for their operation. They have also rendered invaluable and timely engineering service to various government departments and the Council of National Defense.

The American Institute of Metals has coöperated with the U. S. Bureau of Standards in the preparation and inspection of non-ferrous metals and has furnished many men for the Engineer Officers' Reserve Corps.

The American Institute of Architects is handling certain emergency work for the Government through its committees appointed by the President of the Institute. A war-service register has been created, comprising over 3000 names, giving qualifications of architects and draughtsmen. This register has been actively used by various branches of the Government service.

The Illuminating Engineering Society has laid out the lighting schemes for the aviation cantonments for flying by night, an absolutely new problem. The society has also prepared industrial lighting codes for the Welfare Section of the Labor Commission of the Council of Defense. It is also at work on some confidential matters.

The Society for the Promotion of Engineering Education has prepared in detail modifications of curricula for students in engineering to meet war conditions, and has worked out a just modification of the draft law so that students who have been drafted may be assigned to finish courses which will specifically prepare them for government service.

Special information has been furnished the departments of the Government, including lists of all books on the application of engineering to the war.

The National Society for Promotion of Industrial Education has trained several hundred electricians for the Navy in connection with the Electrical School of the New York Navy Yard; it has also done similarly for the Signal Corps and is now training men for Marine service.

The Franklin Institute up to date has recruited 721 men for the Aviation Service. Its secretary is a major on General Pershing's staff and the associate secretary is a lieutenant in the Signal Corps. Investigations have also been made by the Institute for the National Research Council.

The National Association of Master Steam and Hot Water Fitters has furnished engineers and draftsmen to lay out the steam work for power and heating to be done in connection with hospitals, officers' quarters, barracks and other buildings at the cantonments, as well as many other buildings already under construction and to be built for several branches of the service.

The National Association of Engine and Boat Manufacturers has turned over to the Government complete inventories of the members' factories and equipment in order to facilitate the work of the Council of National Defense. Practically all of the submarine chasers ordered have been built in the factories of the members of the Association. Recently an arrangement has been effected with the Society of Automotive Engineers whereby the members of the Association have become represented in that organization with particular reference to the formation of a new Committee on Marine Standards, whose work will undoubtedly prove of immeasurable assistance to the Government.

The American Electric Railway Association has a committee with representatives in the several military departments of the Government, who in coöperation with the Council of National Defense are preparing a comprehensive map of all the electric railways and their availability for war.

In the South, the Affiliated Technical Societies of Atlanta have assisted in the industrial census already mentioned and in recruiting an engineer regiment. So many of their members have gone to the front that they cannot hold meetings.

The President of the Engineers' Club of St. Louis is a major. The club has assisted in recruiting some of the railway regiments now in France, has purchased and presented regimental colors and is arranging to send every member at the front a Christmas gift. It has also contributed to the American Red Cross.

The Engineers' Society of Northeastern Pennsylvania has organized a company of engineers which has been accepted by the National Guard and is now in federal service at Camp Hancock. The President of the society is commissioned as a major.

The Florida Engineers' Society maintains a classification list of men available for special service, and over twenty per cent of its membership are at the front.

The returns from more societies throughout the country seem to point to over ten per cent on the average as being now with the colors.

The Engineering Society of the South has sent its secretary, treasurer and ten per cent of its membership to the front. It is furnishing technical data to the Government, and like other organizations has assisted in recruiting the railway regiments.

THE SOCIETIES AND WAR RELIEF

The technical societies with their obvious professional work have not forgotten war relief.

The Engineers' Club of New York has for nearly three years been giving six hundred dollars per month to the suffering in all countries.

About $11,000 was contributed by members of all societies to what is known as the British Professional Classes War Relief, inclusive of artists and others as well as engineers.

Obviously the technical societies, as organizations of professional men, are not content, with this war on our country's hands, to let anything rest, and at this very moment the representatives of the societies are meeting in Washington to discover how they can serve in the tremendously essential work of the conservation of coal.

There is shortly to be held a conference of all the technical committees to see how they may be coördinated, and a permanent headquarters and staff, all at our expense, placed in Washington at the disposal of the Government.

The technical societies are ready and willing to consecrate every ability to make the Stars and Stripes the symbol of that nation whose citizens are capable of the greatest sacrifice and unselfish service to mankind.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER DECEMBER 10, 1917

Below is the list of candidates who have filed applications for membership since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by December 10, 1917, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about January 15, 1918.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

California

TEASDALE, GEORGE W., Master Mechanic, Potrero Mining Co. of Mexico, Los Angeles

Colorado

MALLORY, WALTER F., Instructor, University of Colorado, Boulder

Connecticut

ARKISON, JOHN T., Superintendent, M. J. Daly & Sons, Waterbury

CUDLIPP, CHARLES W., Secretary and Manager, The Rogers Paper Mfg. Co., Inc., South Manchester

SCOTT, NELLIE M., President and General Manager, The Bantam Ball Bearing Co., Bantam

WEBB, THOMAS M., Process Engineer, Remington Arms U. M. C. Co., Bridgeport

Delaware

ACKART, EVERETT G., Supervising Engineer, E. I. du Pont de Nemours & Co., Wilmington

District of Columbia

WOODWARD, MARK R., Engineering Aid, Bureau of Yards & Docks, Navy Dept., Washington

Illinois

BAILEY, ROBERT W., Agent, Structural Steel and Machinery, Chicago

Indiana

BULL, EYVIND H., Engineer, Green Engineering Co., East Chicago

Louisiana

ROBERTS, THOMAS H., General Superintendent, Stern Foundry & Machinery Co., New Orleans

Maine

HARVEY, WALTER O., Mechanical Engineer, American Thread Co., Milo

Maryland

HUSS, HENRY, Second Vice-President, New York & Hagerstown Metal Stamping Co., Hagerstown

Massachusetts

ARNOLD, Arthur A., Mechanical Engineer and Development Manager, American Optical Co., Southbridge

CLARKE, JAMES C., Educator, Head of Coöperative Industrial Course, Hyde Park High School, Boston

EYRE, JOHN J., Engineer on Rifle Parts, New England Westinghouse Co., Springfield

PERKINS, PERCIVAL I., President, P. I. Perkins Co., Boston

SHUTE, FRANK A., Nightingale & Childs Co., Boston

Minnesota

HAWKINS, ROBERT D., Superintendent of Motive Power, Great Northern Railway, St. Paul

New Jersey

BENNETT, HENRY G., General Manager, International Arms & Fuse Co., Bloomfield

DONOVAN, JOHN T. L., Superintendent and Engineer, Equipment Division, Edison Lamp Works of G. E. Co., Harrison

New York

BATTIN, HAROLD T., Chief Engineer, Horace A. Staples, Cons. Engineer, New York

CONRAD, WILLIAM L., Industrial Engineer, with H. L. Gantt, New York

CORLEY, RALPH A., President, Young, Corley & Dolan, New York

CORY, RUSSELL G., Consulting Engineer, New York

EADIE, JOHN G., Consulting Engineer, Eadie, Freund & Campbell, New York

KIBELE, EUGENE, General Manager, Clark Bros. Co., Olean

LEYSON, DAVID J., Assistant Production Engineer, Savage Arms Corp., Utica

LLOYD, ROBERT MCALLISTER, Consulting Engineer, New York

LUDLUM, ALBERT C., President, New York Engineering Co., New York

MACDONALD, COLIN F., Boiler & Factory Inspector, Rochester

RAHILLY, THOMAS A., Mechanical Engineer, Bureau of Sewers, Brooklyn

STROHMANN, WILLIAM, Chief Estimator and Assistant Chief Clerk of Cost Department, R. Hoe & Co., New York

SWEETLAND, ERNEST J., Vice-President and Eastern Manager, United Filters Corp., Brooklyn

Ohio

NIKONOW, JOHN P., Member, Russian Commission on Inspection of Artillery Orders, at Recording & Computing Machines Co., Dayton

SPENGLER, WARREN D., Electrical Engineer, Firestone Tire & Rubber Co., Akron

Pennsylvania

BATES, ERASTUS N., JR., Assistant Professor Mechanical Engineering, Pennsylvania State College, State College

CHERRINGTON, GEORGE H., President, Brown & Zortman Machinery Co., Pittsburgh

HAMILTON, WALTER C., First Lieutenant, Ordnance Department U. S. R., Frankford Arsenal, Philadelphia

HEERING, ERNEST K., Designing Engineer, Wm. Cramp & Sons' Ship & Engine Building Co., Philadelphia

McKENZIE, JOHN C. S., Special Representative, Erie City Iron Works, Erie

PRESCOTT, PERLEY R., Operating Engineer and Engineer of Tests, Erie City Iron Works, Erie

PYLE, LEWIS M., Designing Engineer, Niles-Bement-Pond Co., Philadelphia

Rhode Island

HOUGH, EDWARD B., President, Wightman & Hough Co., Providence

Washington

CAMMACK, ALBERT, Professor of Steam Engineering, Washington State College, Pullman

Australia
WOOD, ARTHUR, Locomotive Designer,
Commonwealth Railways, Melbourne, Victoria

England
FRYER, FREDERICK G., Chief Mechanical Engineer,
Rowntree & Co., Ltd., York

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

California
FLAM, AUGUST, Mechanical Engineer and Designer, Los Angeles

Connecticut
ADISHIAN, PETER K., Tool Designer,
Pratt & Whitney Co., Hartford
NAUHEIM, S. ALBERT, Assistant Superintendent,
Autotyre Co., Oakville

Illinois
COLEMAN, WILLIAM F., Assistant Manager,
Pyott Foundry Co., Chicago
SHEA, JOHN R., Head of Production Methods Division,
Western Electric Co., Chicago

New York
ENNES, JOHN G., Outside Superintendent,
Bayles' Shipyard, Inc., Port Jefferson
LANYI, LOUIS, Chief Engineer, Fan Division,
Green Fuel Economizer Co., Beacon

Ohio
EIPORT, HARRY E., Charge of Machinery and
Equipment of Dept., Babcock & Wilcox Co., Barberton

Oklahoma
CORNELL, HERMAN D., Vice-President and General
Manager,
Higrade Petroleum & Gasoline Co., Tulsa

Wisconsin

NECROLOGY

EARLE C. BACON

Earle C. Bacon was born on May 29, 1859. He served his apprenticeship with the Delamater Iron Works in New York. While there, though but twenty-one years old, he designed the Bacon trunk-cylinder hoisting engine, which had a patented connecting rod with an inside rod for taking up the wear on brasses. This engine was the first used in New York for lifting brick, etc., in building construction. The same engine is still being manufactured for use as a winze hoist and for surface work around mines.

Mr. Bacon served as consulting engineer and furnished machinery for a great many mining companies, as he made a specialty of mining and quarry work.

He was at different times consulting engineer for the Davis Sulphur Ore Co., the Sulphur Mining & Railroad Co., Virginia, the Nichols Copper Co., the Lavonia Salt & Manufacturing Co., the Bristol Copper Co., and many others.

Mr. Bacon was also a pioneer in the asbestos field in Quebec, being employed as consulting engineer in that line, and designing and equipping the first mill for the reduction of asbestos in that region.

He was a member of the Union League Club and of the Machinery Club. He became a member of the Society in 1885. He died on April 9, 1917.

WILNER E. JOHNSON

Wilner E. Johnson was born on May 16, 1881, in Sweden. In 1903 he began his apprenticeship with the Brooklyn Rapid Transit System as a draftsman in the 52nd St. shop of the System. He held successively the positions of chief draftsman in 1907, engineer of car equipment in 1911, and engineer of car construction for the allied New York Municipal Railway Corporation in 1913.

In 1912 Mr. Johnson made a country-wide study of car designs in relation to speed of passenger interchange, the direct result of which was the development and adoption of the center-entrance type of car, which has since become a model for many other roads. Mr. Johnson's most noteworthy achievements for his company were the detailed working out and development of the Brooklyn center-entrance surface car and the New York Municipal Subway car.

As a member of the committee on equipment of the American Electric Railway Association, he spared no effort to make the committee's researches and standards of real value and of active interest to the industry at large.

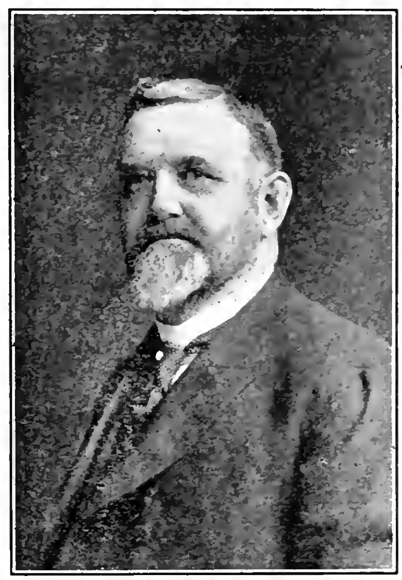
Mr. Johnson became a member of the Society in 1914. He died on July 27, 1917, at his home in Brooklyn.

ALFRED EUGENE KENRICK

Alfred E. Kenrick was born in Brookline, Mass., on February 15, 1851. He was educated in the public schools of that town, and started his apprenticeship at the age of sixteen. In 1885, having learned his trade, he entered into partnership with his father in the firm of Kenrick Bros.

His most successful piece of engineering work is considered to be his invention of the water-heating system for the Brookline Public Bath House.

Mr. Kenrick was an active member of a number of societies in connection with his work. In January 1907 the American Society of Heating and Ventilating Engineers presented him with a silver loving cup in token of his services to that society. He held during his membership in the Master Steam and Hot Water Fitters' Association of the United States every office



Alfred E. Kenrick

within its gift, and on the twenty-fifth anniversary of the Association, in 1913, he was presented with a silver pitcher and salver in appreciation and recognition of his fidelity. He was a member also of the Master Plumbers' Association of Boston.

For over twenty years he served the town of Brookline on its appropriation committee, and for nearly thirty years he was associated with the Brookline Savings Bank, as a member of its board of investment and also as vice-president.

He became a member of the Society in 1896. He died at his home on January 17, 1917.

With the assistance of leading professors in technical schools, business men and social workers, the Advisory Committee for Industrial Service Movement of the International Committee of Young Men's Christian Associations, has prepared a comprehensive outline of suggested college courses on the Human Side of Engineering. The courses are intended to be supplemented by engineering trips to study certain industrial conditions and the betterment work of selected companies.

AMONG THE SECTIONS

IMPORTANT additions to the By-Laws of the Society pertaining to the government of the Sections were passed at the meeting of the Council on October 12. The Sections have now been in existence about ten years, and their activities have extended continuously and uniformly until they now constitute one of the major activities of the Society.

The Committee on Constitution and By-Laws has been working with the Sections Committee for about two years in drawing up suitable By-Laws to cover all the phases of the Sections' work to be found in different parts of the country, to afford the Sections every opportunity to carry on activities of local interest, and at the same time ensure that their procedure be conducted in uniformity with the Constitution of the Society, and the report presented by the former at the October Council meeting represents the consummation of these efforts. The new By-Laws which go into effect immediately are printed below:

New By-Laws Governing Sections

B48 Committee on Local Sections:

The Committee on Local Sections shall consist of five Members, Associates or Associate-Members. The term of office of one member of the Committee shall expire at the end of each Annual Meeting.

It shall be the duty of the Committee to confer with the officers and members of the Local Sections, and to consider, and make recommendations to the Council upon all matters affecting the welfare of the Local Sections. It shall confer with the Finance Committee as to the appropriation for the expenses of Local Sections in each annual budget of the Society, and shall determine the portion of that appropriation which shall be allotted to each Local Section. The Committee shall have such other duties as may be given to it by the Council.

B49 Local Sections:

(a) Formation of a Section

When a number of the membership of The American Society of Mechanical Engineers in any territory desire to form a Local Section, a preliminary meeting shall be called and notice sent to the entire membership of the Society residing in that territory. At this preliminary meeting a petition for the formation of a Local Section, containing suggestions as to the territory to be included in the Section, shall be presented, and if adopted shall be sent to the Committee on Local Sections for presentation to the Council with its recommendation. This petition shall be signed by such of the membership of the Society residing in the territory as favor the formation of such Section.

If the formation of a Local Section be approved by the Council, a meeting of the signers of the petition shall be held for organization and to elect a Local Committee of at least five from among the Section members. This Local Committee shall have charge of and be responsible for the proceedings of the Local Section.

(b) Territory of a Section

The territory of a Section shall include the locality naturally tributary thereto.

(c) Name of a Section

A Section shall be known as The (name of place) Section of The American Society of Mechanical Engineers.

(d) Membership of a Section

All members in every grade of the Society residing in the territory of a Local Section shall be Section Members of that Local Section. A member of the Society shall be entitled to vote or hold office in one Local Section only.

Any other person interested in engineering may be invited by the Local Committee to join its Section as a Local Member, but he shall not have the right to vote or hold office. Such Local Member shall pay dues to the Section not to exceed \$5.00 per annum, which shall be due and payable in advance on October 1 of each year of his enrollment. Local Members shall not be considered in the allotment of expenses to the Section.

Members of Student Branches living in the territory of a Local Section shall be entitled to receive notices of and to attend all meetings of that Section for the period of two years after graduation. Such graduates shall be counted as members of a Local Section in the consideration of the allotment for expenses of that Section.

(e) Activities of a Section

The principal activity of a Local Section shall be the holding of meetings for the presentation and discussion of papers relating to engineering and to the allied arts and sciences; it may also hold meetings for social intercourse.

(f) Meetings and Papers of Sections

The provisions of the Constitution, By-Laws, and Rules of The American Society of Mechanical Engineers, and the precedents of the Society with respect to professional sessions for the discussion of papers, shall govern the procedure of the Local Sections, except that no meeting of a Section shall be considered a meeting of the Society as a whole.

Papers read before a Local Section shall be submitted to the Committee on Publication and Papers of the Society for possible publication in The Journal. The Committee on Meetings of the Society may select from among the papers presented before the Local Sections any paper for presentation before meetings of the Society. A Local Section shall not publish or permit to be published under the authority of the Section any paper as presented before that Section in whole or in part without first obtaining the approval of the Committee on Publication and Papers.

(g) Coöperation of Local Sections

A Local Section of the Society may arrange to hold joint meetings with other local engineering organizations, and may invite members of such organizations to attend its meetings.

A Local Section may affiliate with existing local engineering organizations, or form jointly with them new local engineering organizations, but the plan of such affiliation or organization, and the obligations assumed by the Local Section and the Society thereby, shall first be approved by the Council.

A Section may take action in any undertaking having the approval of the Council, and may coöperate in such action with any other local organization.

(h) Delegates of Sections

Each Local Section shall have the privilege of representation at the Annual Meeting of the Society by one official delegate. Such delegate, the chairman, if possible, may have such portion of his expenses for transportation to the meeting refunded by the Society as the Committee on Local Sections may direct.

(i) Management of Sections

All Local Sections shall be managed in conformity with the Constitution, By-Laws, and Rules of the Society.

Each Local Section shall be managed by a Local Committee of at least five members, consisting of a Chairman, a Secretary,

and such other officers as may be found desirable. Such officers shall be elected by ballot from the membership of The American Society of Mechanical Engineers who are members of the Local Section. They shall be elected before June 1 of each year, and shall take office on July 1.

The Chairman of each Local Section shall receive notices and have the privilege of attending all meetings of the Committee on Local Sections.

The Secretary of each Local Section shall report the Proceedings of that Section to the Secretary of the Society. He shall discharge the duties of Secretary of the Section, and shall perform such other duties as may be prescribed by the Local Committee.

(*j*) *Appropriation for Sections*

Appropriation by the Council for the use of Local Sections shall be used for expenses incurred in holding their professional meetings.

Expenditures chargeable to the Society for purposes of any Local Section must be provided for in the annual budget approved by the Council. No liability otherwise incurred shall be binding upon the Society.

An allotment for a Local Section may be drawn by its Committee as desired, provided that not more than one-half of the total yearly allotment shall be drawn between October 1 to February 1, and that an itemized account of its expenditures during that period shall be rendered to the Secretary of the Society before the remaining amount of the appropriation can be drawn, and provided also that the remainder of the allotment shall be drawn only during the remaining half of the fiscal year, and that an accounting of the second half shall be rendered at the end of the fiscal year.

(*k*) *Stationery for Sections*

All Sections shall use only such uniform stationery as shall be supplied by the Secretary of the Society.

(*l*) *Disbanding of a Section*

The Council of The American Society of Mechanical Engineers may, on sixty days' notice, suspend or disband any Local Section.

Our Present Sections

The Society has now a Connecticut State Section, with branches at Bridgeport, Hartford, Meriden, New Haven, and Waterbury. It also has a Minnesota Section, with meetings held alternately at St. Paul and Minneapolis. Sections are also established in the cities of Atlanta, Baltimore, Birmingham, Boston, Buffalo, Chicago, Cincinnati, Detroit, Erie, Indianapolis, Los Angeles, New Orleans, New York, Philadelphia, St. Louis, San Francisco, Toronto (Canada) and Worcester. The Providence Engineering Society is affiliated with our Society, and its monthly meetings are reported in The Journal with the Sections' reports. The geographical distribution of the Sections is strikingly shown on the accompanying map.

This Year's Work

Two events of importance have started off the Sections' work this year. At the time of going to press, President Hollis is visiting the Sections at St. Louis, Los Angeles and San Francisco, and is also speaking on behalf of the Society at El Paso, Seattle and Portland. At the same time the Committee on Sections is visiting St. Louis, Milwaukee, Chicago and Detroit, to meet the Executive Committees personally and discuss ways and means for Sections' development. Accounts of both these events will be given in the next issue of The Journal.

Below are published some of the plans of the Sections for their work for the coming winter. In common with the other activities of the Society, the Sections have in some cases experienced difficulties at this time on account of committee members, speakers, etc., being called into active service, in consequence of which all have not been able to send in their programs. However, those missing from this issue we hope to publish in the December number. Reports of the first meetings of some of the Sections for the new season are likewise here included.

The Committee on Sections is alive to the opportunities and possibilities of the Sections, and has under consideration means for developing these and making them available to the membership to the fullest degree. The Sections' organization can be made one of the strongest, if not the strongest, element in the life of the Society, for through it the benefits of the Society can be distributed to every individual member, wherever resident. Prospects at the present time for such development are exceedingly bright; there is work to be done, and the Sections Committee and the Executive Committees are ready and eager to do it. With the new By-Laws in force, providing unity and organization for this activity, great and far-reaching results may be looked for.

SECTIONS REPORTS

BALTIMORE

Plans for the coming year are now in progress and it is expected to hold the first meeting of the season early in November, the exact date to be announced later.

A. G. Christie,
Section Chairman.

BOSTON

A most successful meeting was held on October 11, at which it was expected Captain Amann, who has recently returned from Verdun, would speak, but he was called away and Lieutenant Morize substituted most acceptably. Major Edwin T. Cole, Commandant at Massachusetts Institute of Technology, was our guest of honor.

Lieutenant Morize contrasted the differences between the present methods of warfare and those in vogue only a few years ago. He spoke for over an hour to an audience that listened breathlessly to his every word, and at the conclusion of his address answered a number of questions. Major Cole followed with an informal talk on the same subject.

Both speakers were enthusiastically applauded and the thanks of meeting voted them at its conclusion.

Lieut-Colonel L. Rees, V.C., M.C., of the Royal Flying Corps, who has recently arrived from England to assist with our aviation work, was the speaker at a meeting on October 25 which was similar to the one held on the 11th. A full account of this meeting will appear in a following issue of The Journal.

W. G. Starkweather,
Section Secretary.

BUFFALO

The sixth season of the Engineering Society of Buffalo and affiliated branches was opened at the Hotel Statler, on October 10, with 125 members participating. After dinner Mr. Geo. W. Dunham, Mem.Am.Soc.M.E., president of the Society of Automotive Engineers, read an interesting and timely paper on the Internal Combustion Engine and the War, laying special emphasis on the functions and work of the automotive engineer in the great war.

David C. Howard, Mem.Am.Soc.M.E., chairman of the military-affairs committee and vice-president of the Chamber of Commerce, announced plans under way for the organization of engineers in wartime so as to increase their usefulness. Mr. Howard also asked the members to help the government catalogue the various war orders which have been placed in Buffalo and vicinity, and to offer assistance to the manufacturers filling these orders.

Industrial Production was the subject of a paper given by Wm. M. Dollar, Mem.Am.Soc.M.E., at the meeting on October 31. Mr. Dollar said that the essentials of modern industrial production,

such as shop order and cost systems, planning and routing systems, piece rate, premium and bonus systems, welfare work, etc., which have been worked out satisfactorily in larger shops and factories, have proved too cumbersome and costly for the small and medium shops which in the aggregate produce a very large portion of the total output of the country. The speaker, who has made a lifelong study of this subject, pointed out the advantage of such systems to these smaller shops and the benefits to be derived without material addition to the clerical work in shop or office.

LOUIS J. FOLEY,
Assistant to Section Secretary.

CHICAGO

As THE JOURNAL goes to press we would make mention of the visit of the Committee on Sections to this Section on October 21. There will be a luncheon with the Executive Committee and a dinner with representative members present to discuss plans for meetings and coöperation for the coming season; details will be given in the next issue.

Chicago has decided to devote its meetings this year to the discussion of timely subjects, giving predominance to topics likely to bring out valuable information in connection with the war. At this date the following speakers and subjects can be announced:

November 16. Cantonment Construction, by Major P. J. Junkersfeld.

January 18. Airplane Engineering, speaker to be announced.

March 15. Engineering Problems of the New Union Terminal, by G. W. Hibbard.

May 17. Progress of the Shipbuilding Program of the United States, speaker to be announced.

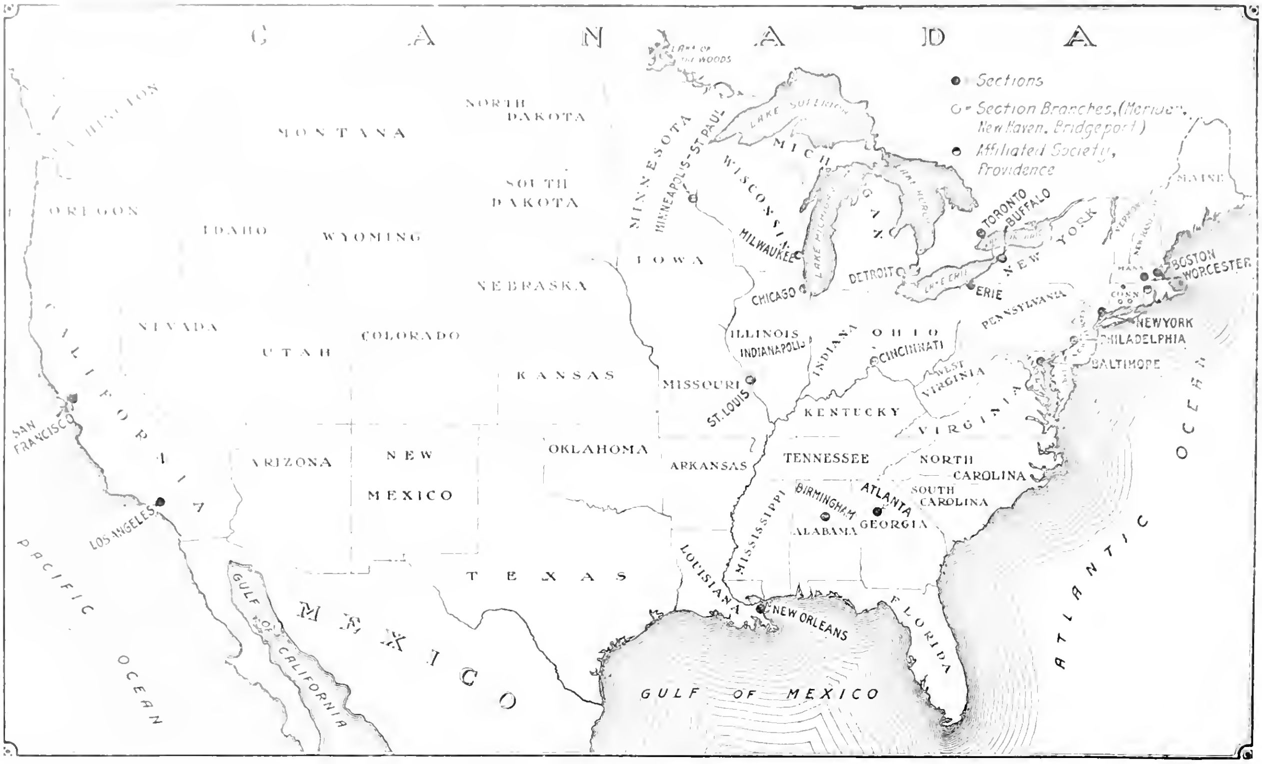
A. D. BAILEY,
Section Chairman.

CONNECTICUT (*Hartford Branch*)

At a meeting attended by men eminent in the profession and prominent in work closely affiliated with the engineering world, the Hartford Branch of the Connecticut Section was organized in the assembly hall of the Insurance Institute on September 28. The local branch will be one of five in the state. Bridgeport, New Haven, Meriden and Waterbury are the other Branches which compose the Section, and members of the Executive Committee of each were present.

The officers elected are as follows: B. W. M. Hanson, *chairman;* Hiram P. Maxim, *vice-chairman;* Sherwood F. Jeter, *secretary-treasurer;* M. D. Church, *chairman* Membership and Acquaintanceship Committee, and C. L. Grohmann, W. H. Honiss, C. D. Rice, A. D. Risteen, C. H. Veeder, members of the Executive Committee.

Mr. Jeter officiated as temporary chairman, and after a brief address introduced President Hollis. Dr. Hollis, in his talk, impressed the necessity for coöperation and sustained interest for the growth and success of the local branch; he advocated regular meetings and fusion of mechanical, civil, mining and electrical engineers, the main point being for the members to meet and exchange ideas. He brought before the audience the great part being played in the war by the engineers and pointed out the important work there would be for the engineer in the work of reconstruction after the war.



GEOGRAPHICAL DISTRIBUTION OF A.S.M.E. SECTIONS

Past-President Jacobus followed with an address on the necessity of petitioning local representatives in Congress in order to bring about good results for the engineering profession. He said there was a time when the national body instructed its members to abstain from politics, but politics are conducted differently now and the individual politician must be reached and convinced.

Secretary Rice spoke of the importance to a municipality of an organization such as this branch. As citizens its members could demand efficient service. In a number of cities, he said, improvements in city streets, water supplies and other important things have been brought about by such organizations as the present one. Ernest Hartford, secretary of the national Committee on Sections, called attention to the numerous desirable opportunities for publicity the Sections have through the columns of THE JOURNAL and the medium of the technical press. F. R. Low, Mem.Am.Soc. M.E., editor of *Power*, told the gathering that owing to new discoveries and great achievements of the engineering profession the world was becoming a better place to live in. P. B. Morgan, chairman of the Worcester Section, told of the work of organizing that Section and hoped that the Hartford Branch would profit by its experience; he also conveyed an idea of some of the problems that might confront the newly organized branch. Henry B. Sargent, of the Executive Committee of the Connecticut Section, described the work already accomplished in the state by the New

Haven Section which now becomes a Branch of the Connecticut Section.

H. B. Sargent,
Section Chairman.

DETROIT

A meeting was held by the Sectional Committee of this Section early in October and officers of the Executive Committee were designated. The chairman was authorized to solicit papers for future meetings and suitable for publication in The Journal.

On October 25 a Dinner-Smoker was held at the Board of Commerce, at which the guests of the evening were the national Committee on Sections. A few select, brief papers were presented on timely topics, including a discussion on Problems of Shop Management by Messrs. Walter Rautenstrauch and D. Robert Yarnall. The plans were formulated for a party to attend the Annual Meeting in New York.

G. W. Bissell,
Section Chairman.

LOS ANGELES

A dinner was arranged by the Section with the Joint Technical Societies on October 23, on which occasion President Hollis and Dr. George E. Hale addressed the meeting. Dr. Hollis addressed the student branch at Throop Polytechnic while in this city. A full account of Dr. Hollis's visit will be given later.

As for the plans of the Section for the year, the Joint Societies will meet at luncheon every Thursday noon and enjoy a short talk, the speaker for the day being furnished by the various societies in accordance with a pro rata list extending through the year.

Francis G. Pease,
Section Chairman.

MILWAUKEE

On October 3 an illustrated lecture by Chester A. Lucas, Mem. Am.Soc.M.E., on the Manufacture of a 9.2 High-Explosive Howitzer Shell, attracted the largest and one of the most interested audiences we have ever had, there being over a thousand present.

With the aid of an actual shell and of lantern slides showing drawings, Mr. Lucas described very fully all the parts of high-explosive shells and also all the machine operations necessary to produce them.

He supplemented this description by motion pictures of the complete process of shell making. The different methods were then shown.

The members of the Committee on Sections arrived at Milwaukee on October 23 and were met by the local committee; luncheon was served at the Milwaukee Club and a visit to the Allis-Chalmers plant made in the afternoon. In the evening a large number of interested local engineers were present at a dinner and took part in a discussion of Society matters. A full account of this visit will appear in the next issue of The Journal.

Fred H. Dorner,
Section Secretary.

NEW ORLEANS

Notes on Shipbuilding was the subject of an interesting paper read by F. J. French on September 7. The speaker illustrated his lecture with lantern slides showing construction work on tank steamers now being built for the Mexican Petroleum Company, of which he is engineer. These are the only steel vessels being built in New Orleans and the paper was received with much interest and caused considerable discussion.

The Section has planned only two technical papers for this year and has appointed a committee to arrange for monthly visits to various industrial plants.

H. L. Hutson,
Section Chairman.

NEW YORK

At the opening meeting of the New York Section on October 16, Dr. T. Kennard Thomson, Mem.Am.Soc.M.E., delivered an address on The Evolution of Manhattan from an Indian Village to a Great Metropolis, contrasting by means of colored lantern slides the early conditions on the island with those now existing. In connection with his address he spoke of the congested port facilities of the City of New York and described a novel plan for relieving this condition, the essentials of which included filling in the present East River and replacing it by a new channel through Long Island, extending Manhattan Island and constructing three new islands in New York Bay.

A. D. Blake,
Section Secretary.

PHILADELPHIA

The following interesting program has been arranged for the coming season by the Philadelphia Section:

October 23. The War's Effect on Merchant Shipbuilding, by Homer L. Ferguson, President and General Manager of the Newport Drydock and Shipbuilding Company. Joint meeting with the Engineers' Club in Witherspoon Hall.

November 27. Program to be arranged and include a visit by the national Committee on Sections. Meeting at Engineers' Club.

December 11. Offensive Against the Submarine, by Jos. A. Steinmetz. Joint meeting with The Franklin Institute.

January 22. Our Navy and the War, by Prof. Wm. L. Cathcart, U.S.N. (retired). Joint meeting with The Illuminating Engineers' Society will probably be arranged.

February 26. Supplement to Taylor's Art of Cutting Metals, by Carl G. Barth, Mem.Am.Soc.M.E.

March 26. Recent Developments in Material Specifications, by Dr. S. W. Stratton, Mem.Am.Soc.M.E., Director of U. S. Bureau of Standards.

Tentative program for the following:

April 23. Major W. P. Barba, Mem.Am.Soc.M.E., and Major A. S. Cushman.

May 28. George Satterthwaite and Professor Henry M. Howe.

June 25. Admiral Taylor and Chester Larner.

PROVIDENCE

The Power Section held an interesting meeting on October 10, at which Professor Dean A. Fales, Mem.Am.Soc.M.E., gave a most interesting talk on The Gasoline Engine, with Particular Reference to Aeronautics.

Professor Fales is in charge of the instruction work in gasoline engines for both the Army and Navy Ground Schools of Aeronautics in Massachusetts Institute of Technology. He described the special problems arising in the design of the aeroplane engine and the present practice in solving these problems. His descriptions of the best types of engines used by the British, French and Germans were extremely interesting.

The Army Cantonment at Ayer, Mass., was the subject of an illustrated lecture given on October 16 before the Providence Engineering Society by F. A. Barbour, who was the supervising engineer in charge of construction of this work.

Mr. Barbour gave a most interesting account of the engineering problems which had to be met to complete this camp within the schedule time. The contract for the camp included 692 buildings to be completed by September 1 and actually ready several days before that time, in addition to 124 buildings, including a 100-bed hospital unit costing \$500,000, refrigerating plants, storehouses, bakeries and miscellaneous buildings. The completion of this \$6,000,000 contract necessitated a force of 9000 men, a weekly payroll of \$400,000, the delivery of 30,000,000 ft. of lumber, the unloading of 50 carloads of material daily and the building of a complete sewerage system with 20 miles of pipe.

James A. Hall,
Correspondent.

ST. LOUIS

The first fall meeting of the Section, held on September 21, was attended by about forty members. The early part of the evening was given over to a dinner, after which a great deal of enthusiasm was aroused by the speakers of the evening.

Judge Thomas L. Anderson, of St. Louis, delivered a very stirring address upon the subject of patriotism, and the remarks he made were very pertinent to the work and requirements of the mechanical engineer in the war.

R. L. Radcliffe, Mem.Am.Soc.M.E., chairman of the Section, brought very forcibly before the members the work which is anticipated by the Membership and the National Sections Committee during the coming year. A committee to arrange for the preparation of technical papers which could be published in THE JOURNAL and a committee on research work were appointed. The committee on program reported the schedule of dinners and papers for which arrangements have been made.

Topics of vital interest to mechanical engineers in St. Louis were then discussed by Messrs. J. Hunter, Mem.Am.Soc.M.E.; L. Gustafson, Mem.Am.Soc.M.E., H. R. Setz, Mem.Am.Soc.M.E., and G. R. Wadleigh, Mem.Am.Soc.M.E., all of whom indicated very clearly to the membership that there was a large amount of work laid out for the coming year and that it was to be carried forward with great earnestness. Indications are that the Section is on a very strong footing and that the work which may be expected of it during the coming year will be of great value to the Section as well as to the Society.

On October 22 a meeting of the Section was held at which Mr. John Hunter, Chief Engineer, Union Electric Light and Power Co., presented a very interesting paper on the recent improvements at the Ashley Street power plant of his company. The progress of the work was shown by lantern slides. The guests of the evening were the members of the Committee on Sections.

THE JOURNAL goes to press as the meeting is being held and a complete report will be given in the December issue.

SAN FRANCISCO

M. M. O'Shaughnessy spoke at the regular bi-monthly meeting on October 16 on the subject of The Tunnels of San Francisco. The speaker described the general features of tunnel construction and the methods of payment therefor, illustrating his remarks with stereopticon views.

On October 25 a joint meeting of mechanical, civil, electrical, mining and chemical engineers, was held with Dr. Ira N. Hollis, Pres.Am.Soc.M.E., as the speaker and guest of honor. Full reports of these meetings will appear in the December issue. The following day it was expected that Dr. Hollis would address the student members either at the Leland Stanford Jr. University or the University of California, and the next day leave for Seattle where he would address the members of the Society in that city on the 29th.

B. F. RABER,
Section Chairman.

STUDENT BRANCHES

The Society has now affiliated with it forty-five Student Branches, which are independent organizations of students in the following educational institutions:

Armour Institute of Technology................Chicago, Ill.
Bucknell College...........................Lewisburg, Pa.
Carnegie Institute of Technology...........Pittsburgh, Pa.
Case School of Applied Science.............Cleveland, Ohio
Colorado State Agricultural College.......Fort Collins, Colo.
Columbia University............................New York
Cornell University...........................Ithaca, N. Y.
Georgia School of Technology..................Atlanta, Ga.
Johns Hopkins University..................Baltimore, Md.
Kansas State Agriculture College..........Manhattan, Kan.
Lehigh University.........................So. Bethlehem, Pa.
Leland Stanford, Jr., University....Stanford University, Cal.
Louisiana State University...............Baton Rouge, La.
Massachusetts Institute of Technology.....Cambridge, Mass.
New York University.......................New York, N. Y.
Ohio State University.......................Columbus, Ohio
Pennsylvania State College................State College, Pa.
Oregon Agricultural College.................Corvallis, Ore.
Polytechnic Institute of Brooklyn..........Brooklyn, N. Y.
Purdue University..........................Lafayette, Ind.
Rensselaer Polytechnic Institute..............Troy, N. Y.
State University of Iowa..........................Iowa, Ia.
State University of Kentucky................Lexington, Ky.
Stevens Institute of Technology............Hoboken, N. J.
Syracuse University.......................Syracuse, N. Y.
Throop College of Technology..............Pasadena, Cal.
University of Arkansas...................Fayetteville, Ark.
University of California....................Berkeley, Cal.
University of Cincinnati..................Cincinnati, Ohio
University of Colorado......................Boulder, Colo.
University of Illinois..........................Urbana, Ill.
University of Kansas........................Lawrence, Kan.
University of Maine..........................Orono, Me.
University of Michigan....................Ann Arbor, Mich.
University of Minnesota..................Minneapolis, Minn.
University of Missouri.....................Columbia, Mo.
University of Nebraska......................Lincoln, Neb.
University of Oklahoma.................Stillwater, Okla.
University of Pittsburgh.................Pittsburgh, Pa.
University of Washington..................Seattle, Wash.
University of Wisconsin....................Madison, Wis.
Virginia Polytechnic Institute............Blacksburg, Va.
Washington University....................St. Louis, Mo.
Worcester Polytechnic Institute..........Worcester, Mass.
Yale University.........................New Haven, Conn.

Institutions in which the entrance requirements are equivalent to those established by the Carnegie Foundation are eligible for Student Branches. Bodies of students in the engineering departments of such colleges are invited to apply to the Secretary of the Society for information regarding the form of petition to the Council for a Student Branch.

The Student Branches are now commencing activities for the year, and accounts of their first meetings appear below.

This Month's Reports

BUCKNELL UNIVERSITY

October 1. The season opened with a well-attended business meeting, and was followed by a lecture on The Standing of the Engineer, by Professor F. E. Burpee, Mem.Am.Soc.M.E.

H. R. PARS,
Branch Secretary.

UNIVERSITY OF NEBRASKA

October 2. Several honorary and regular members were elected at the first meeting of the Student Branch this season.

Dean Stout told briefly of the organization of The American Society of Mechanical Engineers and the importance of Student Branches. He was followed by Professor Seaton, who told of his experience when a student in connection with the Society. E. C. Hurd, a consulting engineer, of Lincoln, Nebraska, gave a short and interesting talk on The Practical Side of Engineering.

R. B. SAXON,
Branch Secretary.

RENSSELAER POLYTECHNIC INSTITUTE

September 30. The first meeting of the Student Branch for the season took the form of a smoker and gave every indication that the Branch will be very active this year.

After the regular business an illustrated lecture was read by Professor Fairfield on the Manufacture of the S. K. F. Ball Bearings. The slides were especially good, and the lecture that accompanied them proved most interesting to all present. Professors Greene, Fairfield, Anderson and DuPriest, who were present, took part in the discussion which followed, answering many questions.

R. A. MARRIOTT,
Branch Secretary.

WORCESTER POLYTECHNIC INSTITUTE

October 5. Alfred C. Carhart, Mem.Am.Soc.M.E., works manager of the Crosby Steam Gage & Valve Co., gave a most instructive and interesting talk at the first meeting on Opportunities to Young Engineers.

The speaker emphasized several points for the students' consideration along the lines of real efficiency, management of men, service to mankind and finding one's real place in the engineering world. Each point was sent home by a pleasing story, as well as serious comment on things as one finds them.

It is seldom that the students have listened to so keen a thinker along industrial-management lines who could, by his mingling of the serious and the humorous, better drive his points home to the mind and heart.

H. P. FAIRFIELD,
Branch Secretary.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

IN forwarding applications, stamps should be enclosed for transmittal to advertisers; applications of non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society.

GOVERNMENT POSITIONS

The Society has been asked to make suggestions of men for the following positions with the Government. Non-members of the Society having the qualifications may avail themselves of these notices by enclosing with their reply a personal introduction to the Secretary.

FIFTY ENGINEERS, with building construction or superintendent's experience for immediate work in France, in construction department of the Signal Corps, U.S.A., to receive the rank of First Lieutenant. Age limit 21 to 40, but men from 25 to 35 years of age are preferred. Technical-school men with military experience desired. Usual army physical examination required. 2254.

PAPER MAKER, familiar with the operation of paper machines, preferably man of experience; not prejudiced against man past middle life. Salary depends upon man. Location New York. 2262.

SIXTEEN ENGINEERS, to have charge under commanding officer of the engineering service in troop cantonment and to receive commissions as Majors in Quartermaster General's Department. Would be called upon to operate and maintain all electrical and mechanical equipment, including heat, light, power, plumbing, roads, sewage disposal and water service. 2272.

ORGANIZING ENGINEER in oil-well machinery, etc., to handle routing of work through the shops. Location Oklahoma. 2280.

SHOP SUPERINTENDENTS, ASSISTANTS AND FOREMEN for arsenal assignments. Location Massachusetts. 2290.

ORDNANCE INSPECTORS, 15 to 20 men, technically trained, with ability and good judgment. 2291.

ENGINEERS who may be classified as secretarial engineers or business managers. Experienced office men who combine engineering education with intensive office experience. Immediate problems have to deal with an increase of office force and erection and equipment of building for office purposes. 2323.

MECHANICAL DRAFTSMAN. Salary about \$150. Location New York office. 2325.

HIGH-GRADE MECHANICAL ENGINEER with technical education and motor-transportation experience in Quartermaster Mechanical Repair Shop, for technical supervision of wagon, harness, clothing, shoe and tentage repair shops. Suitable men will be commissioned Captains. 2329 A.

GENERAL PRODUCTION SUPERINTENDENT of equally high grade for same shops. 2329 B.

FOREMAN, FIRST AND SECOND LIEUTENANTS. 2329 C.

SUPERINTENDENTS for new artillery-munition plant operating for Government. Experienced men to be commissioned for duration of War. Retained in civilian capacity after the War. (A) in general charge of plant, (B) in charge of high explosives, (C) in charge of shrapnel, (D) in charge of manufacture of fuses and primers, (E) in charge of wood-working plant for boxes to ship and pack ammunition. 2336.

ENGINEER of pronounced ability in mechanical lines for Government work. He must be able to build machinery of accuracy and precision, not only superintend the construction of the tools and jigs, etc., but organize an excellent inspection department. Pre[illegible] from St. Louis vicinity. 2343.

MECHANICAL ENGINEER of proven ability, with considerable experience with electric auxiliary machinery and hydraulic [illegible] machinery. Man of very highest standing is desired. Salary not considered commensurate by the Government to qualifications d[illegible]d. It is hoped rather that man of the highest standing in his profession will volunteer his services for this at nominal salary in part of patriotic contribution to success of the War. To act in a more or less consulting capacity in mechanical matters affecting ship design. 2359.

SUPERINTENDENT, with drafting experience on structural steel. College graduate preferred. Age 35. To serve in civilian capacity. Salary \$2000. Location near New York. 2361.

DRAFTSMAN on building construction and structural steel, to serve in civilian capacity. Salary \$1600. Location near New York. 2362.

PLANT ENGINEER on per-diem or annual basis of pay, familiar with layout of factories, especially along lines as similar as possible to armor-plant work. 2363.

CIVILIAN POSITIONS

TOOL DESIGNER who is resourceful and can follow work through to completion. Technical man with practical shop experience. Location Connecticut. 185.

SALES ENGINEERS, between 25 and 30, good appearance, graduates of approved engineering college, preferably M.E.; would be expected to undergo period of probation and training in various offices of company before being given more responsible work. Apply by letter in own handwriting. State age, education, previous business training, if any, salary desired, etc. Location New York. 205.

DRAFTSMEN AND DESIGNERS experienced on valves and fittings. Good future with large concern. State experience in full, salary expected and references. Confidential. Location New England. 1002.

DRAFTSMAN AND ESTIMATORS for work of varied character with large concern. Offers good opportunity for advancement. Location New Jersey. 1104

GRADUATE MECHANICAL ENGINEER with theoretical knowledge of centrifugal machinery, preferably fans, pumps and compressors, also thoroughly familiar with design and methods of testing. Apply by letter. Location New York. 1140.

MECHANICAL DRAFTSMAN on automatic machinery. Salary \$20 to \$25. Location New Jersey. 1168.

TECHNICAL GRADUATE for drafting and engineering department for structural work and machine design. Conveying-machinery experience will be of advantage. Splendid future to right man. State fully education, experience, age, salary expected, etc. Record and applications confidential. Location Missouri. 1185.

SALESMAN, preferably experienced on conveying machinery. Splendid opening with good future for right man. Give full details of experience, age, salary expected, etc. Record and applications confidential. Location Missouri. 1186.

FACTORY EXECUTIVE, technical graduate, 30 to 35, for large textile-machinery manufacturing plant. Knowledge of up-to-date shop methods essential, also successful experience in handling of mechanics. Applicant would be required to spend from one to two years in shop to become familiar with various classes of work, after which position of assistant superintendent with further excellent opportunities for promotion will be open to him. Salary to start about \$2500. Location Massachusetts. 1191.

DESIGNER, experienced on jigs and fixtures for miscellaneous machine-shop production work, including turbines, reduction gears,

[illegible] and [illegible] arranged. Attractive offer to man who would be capable of handling this class of work. Location Maryland. 2008.

DRAFTSMAN for general design of new machinery and improvement of existing machinery in large going plant. Position leads to industrial management work. Give full particulars. Location Maine. 2020.

DESIGNERS, thoroughly experienced in turbines. Salary $200 to $300. Location New York. 2021.

DRAFTSMAN for concern manufacturing wire-rope tramways who would develop along lines of overseeing, erecting, etc. Salary $25 to $30. Location New York. 2032.

DRAFTSMAN familiar with water-wheel equipment. Technical graduate preferred. Unusual future in central Massachusetts concern. 2042.

YOUNG MECHANICAL ENGINEER, industrious and capable, familiar with fuel-economy tests, power plant, and with practical experience in construction and testing of modern Westinghouse steam turbines. Possibilities for advancement to right man. Location New Jersey. 2055.

DRAFTSMAN on a-c. or d-c. motor design. Salary about $40. Location New Jersey. 2058.

DRAFTSMEN on mechanical-stoker work, men familiar with boiler room layouts, building and construction or heavy machine design acceptable. Salary up to $30 to start, depending upon ability and experience. Permanent position. Location Pennsylvania. 2069 A.

DESIGNING DRAFTSMEN experienced in auxiliary marine machinery, hoisting engines, and hoisting-engine design in connection with this class of machines. Salary up to $30. Location Pennsylvania. 2069 B.

TECHNICAL GRADUATE as instructor in mechanical engineering, tracing, machine design, gas engines and machine shops, for southern university. Give age, education, experience, references and salary desired. 2098.

ESTIMATOR for New York concern engaged as engineers and contractors for power plant, ventilation, steam and hot-water heating. 2103.

TECHNICAL GRADUATES. Large growing paper-manufacturing corporation offers excellent opportunity for interesting and effective work to two young technical graduates with tact, initiative, ability and common sense. Non-graduates with two or more years' manufacturing experience considered. Desire men who can develop, and have vision to see and grasp opportunity. Fair living salary offered to start, with future dependent on self. Give complete information. Location Canada. 2105.

EXPERT TOOL- AND FIXTURE-DESIGNING DRAFTSMAN for line of safety valves, steam gages and similar equipment. Must have sufficient education and experience to take charge of drafting department within reasonable time. Location New York. 2115.

EMPLOYMENT MANAGER for plant employing 600 men in Pittsburgh district. Exceptional opportunity for experienced man. 2122.

COMPETENT YOUNG ENGINEER, with good education and previous experience with large concern dealing with marine and power specialties. Location New York. 2158.

PHYSICISTS, CHEMISTS, ENGINEERS, DESIGNERS AND DRAFTSMEN, for work of research, development, and design related to problems of telephonic, telegraphic and radio communication, which are matters of public importance. Opportunities for such men in both temporary and permanent positions. Apply by letter. Location New York. 2178.

PRODUCTION MANAGER, 25 to 33, technical graduate with practical experience. Clean cut, aggressive and of generous build. Work involves handling 500 men to 600 men assembling 1000 to 2000 radiators daily of 12 to 20 different kinds and keeping production moving. Design of tools and jigs taken care of separately, and position in[illegible] of assembled parts. Salary approximately [illegible] Location New York State. 2233.

MASTER MECHANIC, technically educated, experienced in main[illegible] electrically driven mine machinery, air compressors, centrifugal pumps, etc. Two-year contract. State salary and experience. Location Peru, elevation 15,000 ft. 2238.

DESIGNERS for stationary engines of 1000 hp. and larger. Must have theoretical as well as long designing experience. Salary no object; will pay up to $5000 for right man. Immediate employment. Location Massachusetts. 2240.

CHIEF ENGINEER, in charge of designing railroad equipment and supplies, including motor cars, hand, push and velocipede cars, and locomotive standpipes. Technical graduate preferred. Line is competitive, requiring man with business point of view. Salary secondary consideration if right man can be secured. Location Middle West. 2247.

LABORATORY ASSISTANT, capable of making simple chemical tests of lubricants, etc., and investigations into qualities of steel, etc. Location Connecticut. 2256.

MECHANICAL DRAFTSMAN, capable of checking calculations. Location Connecticut. 2257.

YOUNG MECHANICAL ENGINEER to have charge of returned-material department. Work to consist of inspecting all returned material and writing up reports on its final disposition. Location Connecticut. 2258.

SAFETY INSPECTORS capable of inspecting manufacturing plants, contracting risks, apartment houses, hotels, stores, etc., and elevators. Prefer to employ men who have had previous experience in this kind of work with other insurance companies, state rating boards, or those who have held positions as safety inspectors in large plants; but any bright man who has had a mechanical training and is willing to work is in line for a position of this kind. 2259.

DRAFTSMEN for rolling-mill work. Technical graduates preferred. Steady employment and chances for advancement. Location Pennsylvania. 2265.

METER-PRODUCTION MAN, preferably mechanical engineer who understands the making of small meters, etc. Considerable experience in this line and ability to get production essentials. Location Long Island. 2267.

FOREMAN in machine shop, capable of handling standard machines, lathes, boring mills, drills, etc., for conveying machinery equipment. Salary $35 to $40. Location New York State. 2275.

SHOP SUPERINTENDENT for factory employing 5000 men engaged in producing medium-caliber projectiles for Government. Previous ammunition experience desired but not essential. Salary dependent upon ability. Location Pennsylvania. 2276.

DESIGNER of elevators, conveyors and mechanical equipment for industrial buildings. Location Massachusetts. 2283.

MAN OR WOMAN, preferably with technical education, for engineering computation department and the answering of engineering correspondence. Location Massachusetts. 2284.

YOUNG ENGINEER, experienced in general plant-construction work. Good opportunities for advancement. Prefer man exempt from military duty. Location Illinois. 2286.

ASSISTANT PROFESSOR of machine design and superintendent of shops, to teach machine design, mechanical and electrical, give lectures on shop organization and manufacturing processes and superintend work in forge, foundry, wood-working and machinery departments. Salary $1400 for college year. Location New England. 2287.

MASTER MECHANIC for large southern cotton mill controlled by established western corporation with many branches. Policy is to build up such a man from an M.E. or E.E. technical graduate with two or three years' general experience. Married man preferred. Salary to start $1800. Liberal opportunities for promotion. 2293.

YOUNG ELECTRICAL ENGINEER as assistant to chief in research department. Require man with experience, logical thinker, and resourceful habits. Salary $20 to $25 per week. Location New Jersey. 2294.

COAL- AND WATER-GAS MANUFACTURING SUPERINTENDENT. Large and progressive organization in the East considering extensions and reorganization, desires to get into communication with one or two vigorous, experienced executives, having technical knowledge of coal gas and water gas, and ability to keep on top of difficult labor conditions. 2295.

ASSISTANT SUPERINTENDENT OR MASTER MECHANIC. Fine opening for ambitious, progressive man. Salary according to ability. 2296.

DESIGNING SUPERINTENDENT for general supervision and maintenance work in chemical plant. Young man to grow with organization. Salary to begin $1800. Location New York. 2299.

MECHANICAL DRAFTSMAN experienced in working up design of detail parts, and some experience upon general design. Good opportunity with recently incorporated firm in Philadelphia. State experience, references, age and salary expected. 2300.

SUPERINTENDENT for machine shop manufacturing high-grade printing machinery. Must be good executive and thoroughly versed in modern methods of interchangeable manufacture. Give age, nationality and complete experience. Salary depends upon individual. Location New York State. 2301.

ASSISTANT in department of mechanical engineering of large university in Middle West. 1917 M.E. graduate. To help in grading class exercises. Salary $850 to $900. 2308.

MAN to superintend work of laboratory in school of military aeronautics; also man to operate aeronautical engines under their own power. Salary of former $175 to $200 and of latter $150 to $175. Location large university in Middle West. 2309.

DESIGNING DRAFTSMAN for chemical apparatus of all kinds. Location New York. 2311.

ORIGINAL DESIGNING DRAFTSMAN, capable of taking initiative in the design of high tension electrical-power transmission and substation work (32,000 v.). Confine statement of experience to this particular line and be specific. State age, nationality, married or single. $190. Location Canada. 2312 A.

ORIGINAL DESIGNING DRAFTSMAN, capable of taking initiative in design of metallurgical-mill construction and equipment. Confine statement of experience to this particular line and be specific. State age, nationality, married or single. Salary $190. Location Canada. 2312 B.

TECHNICAL GRADUATES. Opportunity for several young technically trained men, preferably with some practical experience in mechanical or electrical engineering. Give age, training and experience. Salary $90 to start. Location New York. 2317.

MECHANICAL DRAFTSMAN, exempt or over draft age, preferably about 35 to 37, good on general design of industrial-plant machinery such as necessary in manufacture of ingredients and dyestuffs. Salary $150 to $175. Location New Jersey. 2319.

ENGINEER in charge of maintenance and repairs, capable of handling 200 or 300 men of varying mechanical trades, and take charge of drafting room. To work directly under vice-president and chief mechanical engineer. Location New Jersey. 2320.

YOUNG MAN with practical experience in shop production; also some knowledge of designing, drawing, etc. Salary $2000 to start, increase according to ability. Location New York State. 2322.

MECHANICAL AND ELECTRICAL DRAFTSMAN, with some experience in power-house design. Salary $100. Location Arkansas. 2324.

CONSULTING ENGINEER to certify to plant and capacity of small snap manufacturing plant in Massachusetts. Italian origin preferred. 2326.

YOUNG MECHANICAL OR ELECTRICAL ENGINEER for office of power plant. Technical graduate preferred. Salary $100. Location New York. 2327.

INSTRUMENT MAKERS. Must be American citizens. Desire men capable of doing bench work connected with the assembly of exact mechanical and electrical devices, skilled in the final fitting for assembling, and capable of reading micrometers and blueprints. 2334.

HIGH-GRADE DESIGNER experienced in distilling apparatus, dieproducts, etc. Location New York. 2337.

ASSISTANT PROFESSOR of experimental engineering wanted by Pacific Coast engineering school. Must have had good technical training in laboratory work, especially along steam, gas-engine and hydraulic lines, also practical experience preferably in operation and installing of power machinery. Previous teaching experience desirable but not required. Salary about $1600, depending on qualifications. Man 26 to 30 preferred. Send complete data, experience record, personal details, recent photo, recommendations, etc., in first letter, as position must be filled as soon as possible. 2338.

TECHNICAL GRADUATE, with three or four years practical experience in efficient operation of boilers and stokers, wanted for position of traveling engineer. Exceptional opportunity for man with initiative and ability to become expert combustion and steam engineer. Work requires extensive traveling in connection with investigation of power plants throughout the country. 2340.

DRAFTSMEN on jigs and fixtures in connection with Government work. Salary $30 to $40. Location Connecticut. 2341.

EXPERIENCED DRAFTSMAN, for power plant and boiler work. Salary $125. Location New York. 2342.

ENGINEER AND DRAFTSMAN. High grade man as head man, or inexperienced man as second man. Location Oklahoma. 2344.

RECENT GRADUATES in mechanical engineering from schools of recognized standing desired for testing work in large steam-operated electric-power plants. Applicants with experience in testing work and now located in and around New York City will be given preference. State education, experience and salary desired. 2345.

ENGINEER familiar with abrasive processes as engineering sales manager with concern manufacturing metal finishing tools and equipment. Location New York State. 2346.

GENERAL SHOP SUPERVISOR, not less than 35, who would be shop representative or director of works. Must be American citizen, who has had considerable machine-shop experience on parts relating to electrical-instrument manufacture. Should be broad-minded, have executive ability, and be capable of intelligently handling minor details connected with shop supervision. Salary about $200. Location New York. 2350.

EMPLOYMENT SUPERVISOR, not less than 35. Must have broad shop practice and training to ask leading and pertinent questions regarding experience applicants have had. Should be good judge of human nature and capable of handling miscellaneous complaints and misunderstandings in shop. Should be systematic; would be required to supervise employees' records and application files, and attend to references given employees on leaving. American. Location New York. 2351.

FOREIGN REPRESENTATIVES for iron, steel and metals, export engineering and contracting, to be given five or six months' training in home office and then employed on staffs of the various local firms representing company in foreign countries. Representative Americans wanted; character, honesty, reliability, loyalty essential. Prefer single men over 30. Must have training as mechanical engineers, technical knowledge of steel; be practical salesmen, with commercial sense and considerable commercial experience. Salary $150 during training period, and as soon as definitely accepted as foreign representative small commission on any and all business done in territory to which assigned. 2352.

PURCHASING ENGINEERS for machinery in the engineering department of export firm. Immediate employment. Training in machine-shop practice, internal-combustion engines, steam-power plants, and some knowledge of electricity as well as of export business desirable but not essential. Salary to start $1800. Location New York. 2353.

ASSISTANT TO FACTORY MANAGER in small rubber-goods factory. Young mechanical engineer, two or three years' experience, who can undertake the design and operation of machinery and relieve factory manager of routine work. Experience in rubber business not essential. Location New York. 2360.

ESTIMATOR, young college graduate, for work in manufacturing and jobbing business. Location New Jersey. 2364.

SALES ENGINEER. Man of mature judgment, sales ability and some mechanical training, capable of meeting high class of prospects, to act as sales representative for a leading automobile-parts manufacturer, with headquarters in Detroit, Michigan. State age, experience and salary expected. 2365.

TWO MECHANICAL ENGINEERS familiar with building construction, power-plant design, installation of machinery. Location New Jersey. 2366.

EVAPORATOR EXPERT. Engineer experienced on design and sale of evaporating apparatus for large concern desirous of extending evaporating business. Letter should contain detailed information as to past experience, qualifications and salary expected. Location New York State. 2367.

CHIEF DRAFTSMAN with executive ability, capable designer, competent to supervise ordering of materials and with capacity for details. Experience in general machine design, structural steel and electrical machinery. Salary $[illegible]. Location New York. 2372

GENERAL MANAGER for concern in the Middle West employing 250 operatives. Product is light hardware in pressed sheet brass, etc. Press and automatic screw machine work, small intricate machines with dies and tools. Should be experienced in locating and buying material, cost accounting, selling and factory management in metal trades. Prefer one who has a desire to become a member of the firm [illegible] capital in expanding the business. 2384

MEN AVAILABLE

CONSTRUCTION SUPERINTENDENT. Japanese, age 42. Fourteen years' [illegible] experience in mechanical and electrical installation work as [illegible] inspector of railroad cars and electrical building construction. At present employed in one of the largest traction companies as power plant and sub-station designer. K-368.

STEAM AND COMBUSTION ENGINEER. Technical graduate, age [illegible], married. Nine years' practical experience with large concerns, including executive experience and the handling of men. Desires change of location. K-369.

MECHANICAL DRAFTSMAN, age 25, experienced in the design, erection and operation of power plants, wishes a permanent position with a power company or consulting engineer. Not less than $125 per month to start. Position in New York City or on Long Island preferred. At present employed. K-370.

CHIEF DRAFTSMAN OR ASSISTANT ENGINEER. Associate-member, age 26. American-born and single, desires change of location. Now chief draftsman of a staff of twelve, totaling a monthly payroll of over $2000. Specialty, large industrial plants, as mining and smelting, covering all branches of engineering. Salary $250 a month. K-371.

SUPERINTENDENT OR MASTER MECHANIC. Associate-member, age 40. Thoroughly experienced in modern factory methods, organizing, planning and supervising the manufacture of interchangeable products. A-1 designer of tools, dies, fixtures and labor-saving devices for rapid production. Has been employed for a number of years in executive capacities as toolroom foreman, master mechanic and superintendent. Lately connected with munitions manufacture as assistant general superintendent of factory employing 500 hands. Immediately available. K-372.

MECHANICAL ENGINEER. Member, age 37, married, with sixteen years' experience in design, manufacture and operation of Diesel and hot-bulb engines for stationary and marine work, will be open for engagement January next. At present prominently connected in this line. Prepared to take charge of and follow up work already started or to design and develop any size or type of marine or stationary oil engine. K-373.

MECHANICAL ENGINEER, age 40, with broad experience in design, estimating, sales, and executive work. Especially qualified for power-plant design and sales, including sugar factories. At present employed as manager of branch office of machinery-export company. Desires position of responsibility where commercial and technical sides of engineering are combined. Speaks Spanish. Position must be permanent and offer a future. K-374.

WAR INDUSTRY MANAGER. Opportunity for active work on war necessities, such as ships, guns or ammunition desired by man of 38, experienced in Corliss-engine building, heavy machine work, and steam-power-plant design and construction. Has held machine-shop positions from apprentice to works manager. Organized and operated for a year a successful shell-manufacturing plant. Rejected for active military service on account of minor physical defect. Present position not directly useful in conduct of war. No position not directly necessary to United States at war will be considered. K-375.

CHIEF ENGINEER OR MASTER MECHANIC, with thorough technical and practical experience, covering construction, operation and [illegible] of steel plant. Specialty, metallurgical work, heating and melting furnaces. K-376.

SAFETY ENGINEER, with six years' thorough technical and practical experience in this capacity with large steel works in Pennsylvania. K-377.

COMBUSTION ENGINEER. M.E. graduate, age 35, with considerable sales experience, would like to devote part time to the sale of high-grade boiler-room specialties on a commission basis, in and around Cincinnati. K-378.

ROLLING MILL ENGINEER, technical graduate, age 36, desires responsible position. Has had fourteen years' experience in entire charge of the design of billet, rod and strip mills, merchant mills, etc.; also complete wire-mill plants. At present employed. K-379.

PRODUCTION MANAGER OR SUPERINTENDENT, member, age 35. Present connection, 17 years with large metal-working corporation; last five years as production manager. Experience covers detailed knowledge of metal trades and manufacturing. Versed in industrial engineering. Location immaterial. Salary to start, $4000. K-380.

FOUNDRY SUPERINTENDENT. Member, at present employed in high-grade plant, desires change. Practical molder, coremaker and melter of gray iron, semi-steel and non-ferrous metals. Technical graduate with broad experience in modern shop methods and various types of molding machines. Good organizer. Can furnish excellent references from present and past employers. Nearly seven years in present position. Must be open shop. K-381.

GRADUATE MECHANICAL ENGINEER, age 30, born in Russia, and speaking Russian. Five years' general machine-shop experience; two years' experience in the manufacture of small tools and instruments; one year in the automobile business. Wishes to connect with concern presently doing business with Russia, or contemplating same after the war. K-382.

EXECUTIVE MECHANICAL ENGINEER, WORKS ENGINEER, CONSTRUCTION SUPERINTENDENT OR DRAFTING-ROOM DIRECTOR. Associate-member, American, age 34, married. Eight years' general engineering experience, covering complete design, construction and maintenance of steam-electric power stations and other public-utility properties. Easily adaptable to conditions; energetic and ambitious. Has reached limit of advancement with present employers. Prefers to connect with an industrial concern in a position offering possibilities. Will be available upon two weeks' notice. K-383.

MECHANICAL ENGINEER OR PLANT ENGINEER. M.I.T. graduate, age 25, desires position in engineering department with opportunity for advancement and greater responsibility. Two and a half years with large textile-finishing concern, in charge of engineering department and drafting office. Experienced in general mill engineering, plant maintenance, machine design, power transmission, building construction, concrete, factory reorganization, installation, and equipment. Can design, supervise, organize or install new work. At present employed. K-384.

MECHANICAL ENGINEER, age 33, with eleven years' estimating, designing and shop experience on boilers, superheaters, stokers and oil burners; also with heating, ventilating and air conditioning, desires position as chief draftsman or assistant to chief engineer or manager of progressive concern, where conditions allow development of ability. Location, New York or Brooklyn preferred. K-385.

EXECUTIVE MECHANICAL ENGINEER. Member, age 41, American, married. Twenty years' practical experience as designer, chief engineer, general manager, and consulting engineer. Thoroughly conversant with all details of shipbuilding, medium-size steel and wooden steamers; machine and foundry, business, manufacture of special machinery and tools; steam engines, boilers, hoisting machinery, dredging and excavating machinery, marine auxiliaries, repairs, estimating, cost accounting, purchasing, management, etc. Desires change, preferably with new company on war contracts, ships, engines, or special machinery. Only permanent executive position considered. K-386.

ASSISTANT TO EXECUTIVE. Graduate mechanical engineer, trained in the electrical industry and accustomed to meeting and handling men, desires position where tact, diplomacy and a keen business sense are required. At present employed in position combining engineering with public relations and commercial activities. K-387.

GRADUATE ENGINEER with twelve years' manufacturing, executive, sales and business management experience. Would make good assistant to executive officer or business manager. K-388.

MANUFACTURING EXECUTIVE for interchangeable parts. Technical graduate, age 32, married. Nine years' experience—four and a half years in last position, as head of department laying out routing cards, ordering and specifying tools for new-parts manufacturing; and as chief inspector. K-389.

EXECUTIVE MANAGER. Mechanical engineer of marked ability, with proven successful record and complete experience necessary to conduct machine tool, precision machinery or similar business. Has directed organization of 12,000 men and served with three leading firms in their respective fields. Now employed but open to consideration for further opportunity. K-390.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and a Selected List of Engineering Articles

American Institute of Electrical Engineers

A MEETING held at Philadelphia on October 8, 1917, was devoted to the subject of industrial research.

Prof. A. P. Kennedy presented a paper on Industrial Research and the Colleges, in which he advocated that a proper relationship should exist in the industrial field between the pure science college, the technical college and the industries themselves, and made an attempt to indicate what this relationship should be.

The speaker defined industrial research as scientific investigation directed economically toward improvements in production.

In the non-technical scientific departments of the colleges and universities are included such fundamental subjects as mathematics, physics and chemistry. The teaching and the learning, the latter by carrying on researches in the above-named sciences, have to be carried on interdependently and perpetually. It is probably undesirable that the pure-science departments of colleges and universities should continuously undertake industrial research, because there is so much other important work to be done which calls exclusively to the province of these departments. In physics, chemistry, mathematics there is a limitless field of undreamed-of knowledge where the instructing staffs in the colleges have special facility for advancement. Barring exceptional conditions, such as those due to the present world war, as a general rule, the best contribution of these departments to industry is by restricting their attention to pure science.

The position of the engineering and technical schools is somewhat different. Their field of activity is intellectually narrower, but, on the other hand, they come into closer relations with the needs and problems of the industries. There are various ways in which technical colleges can assist in industrial research, the selection of which depends on conditions of each individual case.

Younger industries, lacking their own research facilities, naturally turn to the technical colleges for help. This is a call which the colleges would desire to meet so far as they can do so without disrupting their regular work of teaching and learning. The stumbling block in the way, however, is the need for secrecy, as the whole atmosphere of any healthy college is one of intellectual freedom, with all knowledge placed at the academic disposition of everybody around.

In the long run, it seems most desirable that the technical colleges should always carry on general researches in their laboratories of such a nature as may advance applied science, stimulate careful observation on the part of students, contribute to the published fund of available technical information and supply new knowledge to the teaching staffs and train students for entering industrial research. Simultaneously, a limited amount of industrial-research work may also be advantageously carried on in the college laboratories.

An ideal international system would be one in which the pure-science colleges should lay the foundations of future industries by enlarging and disseminating the world's knowledge of the basic scientific principles, the technical colleges should do the same for applied science, while at the same time taking a share in the economic applications of science to industry. The industries themselves should undertake their own researches under the guidance of qualified research specialists. Vocational schools would train industrial foremen in the elements of the same principles of science, art, technique, economy, thrift and hard work, as applied to those particular industries in which each nation is, by its peculiar circumstances, specially adapted to excel.

This paper was followed by an address by C. E. Skinner on industrial research and its relation to university and governmental research.

The author divided research activities into three principal classes: university, governmental and industrial.

Of greatest interest is what the author said as to university research. In his opinion, the principal function of university research should be to train research men. Men with the broadest and best training possible are going to be required in ever-increasing numbers for every possible phase of the work. The fundamental training of these men must be gotten in the university, and universities should be equipped to turn out research men just as they are now turning out men with academic and engineering degrees.

In this connection, it is rather a sad fact that the university has not been able to make its teaching positions more attractive by providing compensation more in line with that obtainable in other fields. While writing this paper the author received letters of inquiry for several men for teaching positions, with specifications which could be met only by men of considerable experience. The compensations named were very much less than those which men with the same qualifications could command in other lines.

The teaching profession is said to have many compensations, such as short hours and long vacations, but the average salary is certainly not one of these special attractions. We have splendid endowments for buildings, and sometimes for equipment, but practically no endowment for men of genius who might make notable progress in pure research and at the same time serve as teachers and examples for the training of men for the whole field. If it takes a genius to recognize a genius yet undeveloped and properly stimulate and direct him, how necessary it is that we place men of genius at the head of the research departments of our universities.

Society of Automotive Engineers

AUTOMOTIVE engineering in the great war formed the subject of an address by Geo. G. Dunham before a recent meeting of this society. The term "automotive," according to the speaker, includes the motor-car, aeronautic, tractor, motor-cycle, marine- and stationary-engine fields; in fact, every type of self-propelled vehicle. In time of war these problems become of particular importance, and that is why

the automotive engineer must enter the Government service, as many have already done, or otherwise discharge patriotic duties by the closest cooperation with those in authority.

It is evident that this is not only a war of engineering competition, but that the internal combustion engine is one of the most vital elements in every phase of its conduct, a condition which will explain the reason for the extraordinary activities of the S.A.E.

The automotive engineers have to take charge of the problems to be met in keeping the fleet of army trucks in operation, problems far more serious than those encountered in normal peace times. Wretched conditions of roads and excessive loads make the necessity of repairs and renewal of parts acute. It has been stated on good authority that frequently two-thirds of the trucks on the Western front are out of commission awaiting or undergoing repairs. While this would indicate the imperative necessity of standardization, the Allied governments have not yet adopted a single standard motor-truck design. The American government has already done so and in this was actively helped by the automotive engineers.

As a result, the Government has in process of production a truck which is not only rugged and finished as a design, but is capable of rapid production and above all simple and easy repair, the parts being made with the view to easy renewal and absolute interchangeability. There is also a smaller number of parts and, in many cases, the same parts have been used in both of the two sizes thus far designed.

These trucks were designed primarily by and for the Quartermaster's Department, but will probably be largely used by other departments requiring fairly heavy equipment. On the other hand, the Signal Corps will require relatively light high-speed trucks to act as aeroplane tenders. These trucks will be mounted on pneumatic tires and be capable of a speed of abount 50 miles per hour. In the Medical Corps a somewhat similar chassis is to be used for ambulances. In the Ordnance Department a quite different set of conditions must be faced. The increase in scarcity of horses, the necessity for greater speed and greater tractive effort have made it necessary for the Ordnance Department to undertake extensive motorization of its equipment. Accordingly, a group of automotive engineers, men, for the most part, with experience in the design of tractors, are now working on this problem. In addition to the tractors used by the Ordnance Department a large number of 4-wheel-drive trucks will be provided for the handling of ammunition and other similar purposes.

There is another branch of automotive engineering about which much less has been written, but in which work of great importance is being done—the development of small stationary or semi-portable units for the operation of wireless sets, searchlights, pumps, isolated electric lighting plants and machinery in portable repair shops.

Perhaps, a still more important work done by automotive engineers is concerned with the development and production of the farm tractor. This type of agricultural machinery is playing a tremendous part in the production of food, which, after all, may be the determining factor in winning the war.

The speaker also discussed in some detail the part played by automotive engineers in the development of standardization of motor cycles and aeroplane engines.

American Foundrymen's Association

During the past few months several organizations have chosen Boston as the meeting place for their convention, and the latest of these, that of the American Foundrymen's Association, took place in that city during the week of September 24.

Each morning during that week was given over to business sessions and discussions of foundry subjects covering gray cast iron, malleable cast iron, and steel; while the afternoons were devoted to pleasure trips and sightseeing.

During the week the exhibit of foundry equipment, supplies, etc., attracted many foundrymen to Mechanics' Building, where spaces were taken up by about 160 different exhibitors. The exhibit opened on Monday, at 9.30 a. m., with a simple but patriotic program particularly fitting at this time, and this was repeated each succeeding day of the convention at the same hour in the morning and at 2.30 in the afternoon. It consisted of the formal raising of the American, British and French flags, on the stage in Grand Hall, at the call of the bugle.

This exhibit being a little different from most of those seen at Mechanics' Building, in that the materials exhibited were not particularly interesting to the general public, was, nevertheless, an extremely interesting and instructive one to the foundryman, and it was estimated that thousands of dollars in contracts were placed during that week.

In the different exhibits, the condition of the times seemed to be taken into account, in that the efforts of the exhibitors were along the lines of maximum speed and quantity with less labor and materials.

The labor question being as it is at the present time, it is very evident that every effort should be made toward getting out work with as few men as possible, at the same time keeping the quality and output at the highest point.

This was seen in the various types of molding machines exhibited where hand ramming was done away with and all the movements controlled by the turning of valves.

The show taken as a whole was a very attractive one, and several exhibits were especially artistic. One in particular received a considerable amount of attention: that of the New England Coal and Coke Company. It consisted of a reproduction of Bunker Hill monument built up of coke by that concern. The monument itself reached nearly to the ceiling of Grand Hall and was surrounded at the base by four large statues of typical Puritans.

The exhibit was indeed an attractive one, and drew the attention of over two thousand visitors from different parts of the country.

F. H. COLE.

National Welding Council

On Tuesday, September 25, at a meeting held at the Engineering Societies Building, New York City, representatives of the various societies and manufacturers interested in welding organized what is to be known as the National Welding Council. This council is intended to be somewhat of a permanent organization, at least until this work shall have been completed. Its object is to thoroughly investigate autogenous welding both as to theory and practice, particularly as applied to pressure vessels, utilizing the knowledge and data at present available, and going into further research work if it is found necessary, and all of this with a view of ultimately formulating a code which shall be used to regulate the practice of welding after the manner of the present Boiler Code.

Meetings are to be held monthly, the third Wednesday being the day now set, and the outlook now seems to be very good for definite results.

F. L. FAIRBANKS.

U. S. BUREAU OF STANDARDS

THE following abstracts, with the exception of the last one, have been composed from material courteously supplied to THE JOURNAL, in response to its request, by the Director of the Bureau of Standards.

The last abstract, describing a feature of the activities of the Bureau most intimately connected with the present war, was taken from *The Automobile and Automotive Industries*.

Particular attention is here called to the intensely practical nature of the subjects investigated by the Bureau of Standards. To cite but one instance: properties of glue. Hitherto there were but few concerns which used glue on a large scale in high-grade products, and which had more or less adequate means of testing this capricious material. Not even all glue factories could tell, and prove, what kind of product they were making.

The growing application of glue, especially for aeroplane propellers, necessitates a clearer understanding of the behavior and properties of this material, and the investigation by the Bureau of Standards is therefore a timely one. That it will cover the subject in a scientific as well as exhaustive manner will not be questioned by any one who is at all familiar with the usual type of work by our national laboratory.

Sole-Leather Testing Machine

The Bureau of Standards is using its new type of leather-testing machine in investigating the durability of the shoes of postmen in the District of Columbia. About 20 different brands of sole leather are represented. The relative behavior of these leathers in service will be compared with the results of the laboratory tests, as a basis for developing a standard method of testing sole leather.

The Properties of Glue

The Bureau is conducting an investigation to correlate the physical and chemical properties of glues, with a view to the formulation of rational standards of quality.

Optical-Glass Production

The Bureau of Standards has produced on a manufacturing scale all kinds of optical glass required for military purposes. The Bureau is now coöperating with the manufacturers of glass in the actual production of optical glass in the quantities and kinds required. One critical problem solved was the production of suitable pots in which to melt the glass. The Bureau was obliged to make pots for this purpose which would not discolor the glass and which would not be eaten through during the melt. As yet the pots commercially available are unsuited to the purpose.

Graphite Crucibles

The production of graphite crucibles has been perfected. Eighteen mixtures were made which showed satisfactory service tests.

Researches on Metals

Progress is being made in the metallographic and chemical survey of ingots and blooms, much of the work being done on night shifts. The investigation of the effect of casting and molding methods upon the strength of test bars for copper is being continued. Many castings have been made for investigational purposes. Experimental heat treatment of the steel rings used for ball-bearing races was made as a basis for the magnetic tests for mechanical properties.

Testing of Columns Under Fire and Load Conditions

In the comprehensive program for testing the fire-resistive properties of materials, the Bureau has just tested three columns of gravel concrete under conditions of load and fire and three of limestone-concrete columns under load without fire. The gravel concrete columns showed failure in the outer shell early in the test. This is attributed to the expansion of the outer shell or layer of concrete. The limestone columns thus far tested show no such tendency, the heat penetrations being correspondingly less.

Electrical Conductivity of Porcelain

About one hundred determinations of electrical conductivity of porcelain have been made up to temperatures of 1000 deg.

Military Research

The Bureau is engaged on researches and investigations having direct military application, and involving physics, chemistry, and engineering. These researches are, for the most part, confidential. A very interesting line of work of this kind has to do with the system of standardizing gages for munitions plants and arsenals.

Apparatus for Studying Stresses in Fabrics

Special apparatus has been prepared in the Bureau of Standards for studying the distribution of stresses in fabrics when subjected to a uniformly distributed pressure. The purpose is to aid in the economical design of certain structural fabrics and to obtain a clearer understanding of the control of the variables in textile manufacturing. The testing apparatus for textile research is placed in a room in which the humidity is maintained at a standard constant value by means of humidifying apparatus and control designed and constructed at the Bureau.

Liberty Motor Testing Plant

Description of the aeroplane-motor-testing plant at the Bureau of Standards grounds, in which is a vacuum chamber for the testing of aeroplane engines at atmospheric conditions ranging from that found at sea level to that found at an altitude of 20,000 or more feet. In this chamber the engine can be started at sea level and "fly" as high as need be for observation purposes, and it can "land" as quickly or as slowly as desired.

The chamber is 6 by $6\frac{1}{2}$ by 15 ft., with walls 12 in. thick, made of concrete and reinforced with steel, and not only is the reduction of pressure arranged for, but provision made to care for the exhaust of the engine. Provision also has been made for the heat produced by the engine which, in the open

upper sky, would be dissipated. There is a mounting similar to that for an aeroplane, and the air left in the chamber is kept in rapid motion when tests are on.

One end of the chamber has big refrigerating coils, filled with ammonia, and five big fans provide the circulation. Openings in the side were made necessary for passage through them of water, ammonia, thermometers, pressure gages, and other devices. A shaft runs through a stuffing box to the outside to connect with an electric dynamometer, to observe the power up to 150 hp. The compartment is lined with cork, and the air that supplies the chamber must be brought in at a temperature to correspond with 0 deg. fahr., which aviators find 20,000 ft. above the ground.

Surrounding the chamber is a stucco structure, 21 by 50 ft., containing the ammonia refrigerating plant, an exhaust blower with a capacity of 1500 cu. ft. per min., weighing devices, measuring arrangements for estimating water and heat, including the heat which escapes in the water, the heat which escapes in exhaust gages, and also the heat that leaves the engine in the circulating air around it; also, for gaging the temperatures of air and water, for indicating the pressure of the air in the vacuum chamber, the volume of air used to supply the engine, the power and speed generated, and various other factors.

Doors leading into the chamber weigh 500 lb. each, and they are made so the covering will fall off in case of an explosion, that the chamber may not be wrecked. For observing the test, port holes, covered with glass an inch thick, are provided. (*The Automobile and Automotive Industries*, vol. 37, no. 14, October 4, 1917, *d*)

Eye Accidents in the Industries

The outbreak of the European war brought such a shock to labor conditions that a period of unemployment followed. By the end of the first year, however, the equilibrium was again established, and with the decrease of workers in Europe came the demand for greater manufacturing in the United States than ever before. As a result of the necessity for increased output, the demand for labor became so great that workers unacquainted with industrial hazards entered munition and other factories. That the Committee might know exactly how these new difficulties were being met, the national organization undertook an intensive study of factory conditions in Buffalo, New York. The work of investigation is now completed, and it is expected that a full report will appear in 1917. (Eighth Annual Report of the New York State Committee for the Prevention of Blindness, Nov. 1, 1915 to Nov. 1, 1916)

How to Aid Workers Hurt in War

Every country that has sent men to the front must face the possibility of having some returned crippled and disabled. What to do with these men and how to do it will be the gigantic problems that must be faced, and our ability to solve them successfully will depend to a great extent upon the amount of previous planning and preparation. It is not a pleasant subject for thought: one would readily shut his eyes to it until we find ourselves with our quota of crippled workers, for whom there seem little means of providing a livelihood.

Almost a thousand members of the National Association of Manufacturers, representing great industries in every section of the country, have sent written expressions of their desire to participate in a practical way in the economic rehabilitation of men injured in the war.

That disabled soldiers and sailors have an inalienable right to maintain their positions in their communities with self-respect and independence is unquestioned, and any suggestion that the situation be handled through charitable organizations shows a shocking disregard of the rights and feelings of those who have made supreme sacrifices for their country; to force them to become public charges is obviously as unfair to them as it is to the community.

The consensus of opinion among manufacturers so far questioned seems to be that the fairest way of helping wounded men is by helping them to help themselves, and they unanimously pledge their coöperation.

So far as the employment of disabled men is concerned, a safe generalization is that occupations needing strength and endurance rather than skill are for the most part closed to such workers. The various lines of the iron and steel industry come under this category, and as a Pennsylvania iron and steel company writes: "Our operations would afford a poor place for the employment of men crippled in the present war, as the work is dangerous, and unless a man is able to take care of himself, he is at a serious disadvantage." (*Journal of Commerce*, September 18, 1917, p. 5)

River Barges Moved by Artificial Wave

With the Ohio River at summer stage, thousands of tons of coal were brought to Cincinnati harbor from the upper river districts recently on the crest of an artificial "flood wave." The experiment was made under the direction of Colonel Beach of the United States engineers of that district.

By allowing the pool waters in tributary streams to be released, through lowering the dams, Colonel Beach created an unnatural "wave," which, entering the Ohio, gave a stage high enough to float down the loaded barges. The opening of the dams was carefully timed, and as each new supply of water swept into the parent river, the stage was maintained and the barges reached Cincinnati safely.

So successful was the trial that a conference of coal shippers was called at once at Marietta, Ohio, and arrangements were made to use the "artificial flood" at regular intervals during the low river stages. Colonel Beach explains that this new method will release thousands of coal cars and help to no small degree in lessening the demands on the railroads. (*Christian Science Monitor*, September 11, 1917, p. 5)

Possible Use for Waste Timber

By using timber heretofore used only for firewood and considered worthless for any other purpose, a new industry is being started in Mississippi, and its rapid growth gives promise of its attaining considerable magnitude and influence in the state.

Refuse wood is being cut into blocks 2½ ft. long and from six inches to more than two feet in width and thickness. White oak and hickory blocks are then shipped to factories for making wagon and buggy spokes, while red-oak and water-oak blocks go to furniture factories to make small articles of furniture.

Several cars already shipped North have found ready markets, and this, with the fact that the waste wood supply is unlimited in this section of the state, has made investors believe that the industry will be a permanent one. (*Christian Science Monitor*, September 11, 1917, p. 7)

Research Progress in Britain

The report of the Advisory Council of the Privy Council Committee on Scientific and Industrial Research for 1916-17 has recently been published. The report is prefaced by a report of the Privy Council Committee, in which is a recommendation that the sum of £1,000,000, handed over by the government to the imperial trust for the encouragement of scientific and industrial research, should be spent in the form of grants in aid to firms in an industry undertaking research, and who may combine to conduct such research on a coöperative basis.

The report of the Advisory Council is divided into two parts. Part I describes the steps taken to deal with the problem of industrial research where practicable on the coöperative basis, and by the department itself where independent state action is required. Substantial progress, the report states, has been made towards establishing a national research association in connection with the great staple industry in cotton, and a scheme of procedure has been worked out in considerable detail. Woolen and worsted manufacturers in Great Britain are following suit, and a provisional committee has been appointed to draft the constitution for a research association. Irish flax spinners and weavers, it is stated, have also decided to take the same step.

"There are also a number of industries," the report continues, "which are so circumstanced that their firms are unable to combine in this way. In some cases the leading firms fully realize the value of science and of combined attack, but they cannot as yet carry the industry with them. For example, the papermakers are urging the council to establish a state laboratory, to the initial and maintenance cost of which they are anxious to contribute.

"The Council note that there are important fields which research associations cannot expect to cover, one of these being research into fuel. Here they consider it simpler and more just that all should contribute through the taxes to the cost of the research. A fuel-research board has, therefore, been formed by the Council. This board has presented its first report, in which are outlined its proposals for taking stock of the coal resources of each district and for classifying, according to their qualities, the seams which are being worked or which might, in certain circumstances, be worked, and ascertaining broadly the industrial uses to which the different kinds of coal are being put." (*Christian Science Monitor*, October 5, 1917, p. 3)

Six-Hour Day for British Labor

That the study of labor conditions, as developed by the war, had demonstrated the advisability of a six-hour working day was the statement of Lord Leverhulme, president of the Welsh National Eisteddfod, made in an address at the annual meeting of that body. Lord Leverhulme is chairman of Lever Bros., Ltd., the soap manufacturers. In his address he also discussed the financial conditions growing out of the war. In part, he said:

"We have learned much the last three years on the subject of fatigue, overwork, and excessively long working hours. We have proved conclusively that prolonged hours of toil, with resulting excessive fatigue, produce after a certain point actually reduced results in quantity, quality, and value than can be produced in fewer hours when there is an entire absence of overstrain or fatigue. Fortunately, however, this logical effect of overlong hours of continuous work does not apply, except to a very limited extent, in the case of machinery and mechanical utilities.

"Therefore, we shall require an enormous increased output of goods to replenish stocks that have been allowed to run down both for our home and export trade, and as we have the machinery available, and which hitherto in most industries has only been run 48 hours per week, a solution of this one of our difficulties can be best and most readily found by working our machinery for more hours and our men and women for fewer hours. We must have a six-hour working day for men and women, and by means of six-hour shifts for men and women we must work our machinery 12, 18, or 24 hours per day.

"In considering the six-hour working day and its advantages for increased output with lessened overstrain and avoidance of overfatigue, we must not overlook the great assistance it will be in solving the problem of education. Our men and women working in factories and mines and allied occupations, including clerical work—in fact, any form of work that is from its very nature mechanical, arduous, or monotonous—have been employed during such hours each day that from mere lack of time and opportunity they can never receive proper education, and are consequently undereducated. If to these conditions of hours occupied in daily labor you also take into consideration, as unhappily must often be the case, to arrive at its true bearings on the problem of education, that our workers are often also underfed, underhoused and overcrowded in insanity kill-joy homes, how can we wonder at what is called 'labor unrest'?" (*Journal of Commerce*, October 2, 1917, p. 5)

A German Appreciation of Enemy Aircraft

A number of French and British aeroplanes which have fallen into German hands have been exhibited at the Berlin Zoological Gardens. The exhibition contained 31 machines, most of them complete, but a few with the motors removed. Of these 15 were British, 15 French, and one Russian. There were also exhibited a number of engines, some more or less damaged. Three of the machines were hydroaeroplanes.

Nine of the machines were single-seaters and 22 double. Five were monoplanes and 26 biplanes. Nine had stationary motors and 13 revolving ones, while two had two motors each. In seven machines the engine was behind the pilot, and in 22 in front, while in two it was at the side. Among the makers represented were the Franco-British Aviation Company (1 machine); Deperdussin (1); Nieuport (5); Morane-Saulnier (3); Farman Bros. (1); Caudron (2); Voisin (1); Blériot (1); Ferner Vickers (2); Martinsyde (1); Sopwith (1); and Avro (1), with six of the British Experimental Co. and four of the Fighting Experimental Co.

The general comment made on these machines in an article in the *Zeitschrift des Vereines deutscher Ingenieure* is that they are not nearly so well finished as the German machines, nor so comfortable for the pilot, and the arrangement of the levers and instruments is criticized as unpractical. It is admitted that the short life of the machines may be a justification for not spending too much time on their finish; on the other hand, it is argued that the permission for poor finish may be an inducement to pay insufficient attention to the vital parts of the machine. Surprise is expressed that the Allies are still building machines with the engine behind the pilot, although the utility of such machines is admitted as giving a free field for vision for navigation as well as for the use of the machine gun.

The machines are divided by the enemy critics as being built on two different principles. In one class it is said that [illegible] aimed at with the sacrifice of non-resistance to [illegible], but it is remarked that if such machines are to be serviceable they must have a comparatively small pressure on the planes, that is, they must have a great plane area for a given weight. They are considered to have powerful engines in proportion to their weight, but as the engine power is practically only of importance in its relation to the load to be carried, the machines are none the less regarded as efficient. Into this category are put the machines of Voisin, Farman, Caudron, Fighting Experimental, and Vickers, all with motors behind or with two motors. In the other class the principal endeavor is said to have been to reduce the air resistance to the minimum possible; the machines are therefore heavier, but permit of a greater load per square foot of plane surface.

The Voisin machine, with its tangle of wire stays, is picked out as the extreme of the first type, and as a contrast the British Experimental is named as the best representative of the second type. In the latter machine the air resistance has been reduced to a minimum, the body of the machine being so narrow that openings have to be cut into the side to give the pilot elbow room. It is also mentioned that even the wire stays are of a lentil-shaped cross-section to reduce the resistance to the air. Other criticism and comparison are withheld, except for the remark that for German machines the second type has always been followed. Similar requirements are believed to be fulfilled by the first class, but the means by which they are arrived at are criticized as primitive.

In conclusion, it is pointed out that the exhibition must in no wise be considered as representing the present state of the art of building aircraft among the Allies, the latest machines not being exhibited. (*Times Engineering Supplement*, August 31, 1917.)

Chemistry and Finance

At a meeting of the New York section of the American Chemical Society on September 28, 1917, the subject of Chemistry and Finance was taken up, with particular reference to the true relation of banking to chemistry. The subject is an interesting one and suggestive of the connection between engineering developments and finance. It is well known how in Germany the close coöperation between the engineer, in particular, the inventor, and the banker, has helped the progress of industry in that country.

The two addresses made at the meeting, one by Dr. A. D. Little, Mem.Am.Soc.M.E., of Boston, Mass., representing the chemist's side of the question, and the other, by Mr. G. A. O'Reilly of the Irving National Bank of New York, showing the banker's point of view, comprehensively presented the situation as it is in this country.

The basic idea in Dr. Little's address was that the time has come for chemists and bankers to find a common language and establish a mutual understanding. Some bankers are finding it worth while to study Spanish, because it leads them into a new financial world. It is in the power of chemistry to open up a new universe of finance.

The speaker pointed out, however, that the chemist has not learned the proper formula for presentation of his projects, especially large ones, to bankers. In the case of a chemical [illegible], especially where new processes are involved, a generous allowance must be made for unforeseen expenditures. Chemical investments in their various stages are undoubtedly speculative, and often highly so in character.

The banker's viewpoint was expressed by G. A. O'Reilly, who stated that the point of contact of the theories of banking and the practice of chemistry is a subject which, it is feared, has not claimed the attention of banking circles in the past to the extent to which its merits would appear to entitle it. However, these are not normal conditions in the least, and questions are handled in a way different from that of pre-war days.

The true relation of banking to chemistry is to found only in the very simple and easily understood theory of practical business. The situation is not difficult unless we are unreasonably disposed to make it so.

For a complete text of both addresses the reader is referred to *Metallurgical and Chemical Engineering* for October 15, 1917.

This Month's Abstracts

An interesting discussion on the fatigue of brasses, especially under alternating stresses, is presented in an abstract of a paper by Dr. R. Archer Haigh before the Institute of Metals. One of the interesting conclusions to which the author comes is that the nature of elongation produced in copper is the same, no matter whether produced by a pulsating or steady stress. It also appears that the value of the ratio between the limiting maximum stress for 1,000,000 cycles and the ultimate tensile stress of the metal is highest for those metals which show considerable reduction of area at fracture in the tensile strength test.

In the section Fuel are presented, in the form of a table, some of the data of tests of a powdered-coal-fuel installation for steam generation on a Western railroad, showing that it is fully possible to burn powdered fuel commercially.

Fred B. Seely, in a Bulletin of the Engineering Experiment Station of the University of Illinois, presents data of a very interesting investigation on the effect of mouthpieces on the flow of water through a submerged short pipe.

That a short stroke is conducive to an increased life of a die is the claim made by E. F. Creager, who supports it by data of his particular experience. He also gives some valuable pointers on the design of presses and describes the little-known devices for oiling the steel strip before punching.

In the section Mechanics attention is called to the abstract of an article by W. M. Wallace on the critical speeds of loaded shafts, in which is discussed the case of a shaft carrying two symmetrically disposed similar cast-iron disk loads.

From data given out by the Society of Automotive Engineers are reproduced a brief description and illustration of the United States military truck, commonly known as the Liberty truck. The history of this engineering achievement was fully told in the daily press. Data contained in the present abstract will give an idea of the simplicity and expediency of the general features of its design.

In the section Pumps are given two abstracts dealing with air pumps. We have reference to tests carried out at the Carnegie Institute of Technology on a small Roots pump, with the view of determining the quantity of air which such a pump can handle. The second article gives some data of tests of a Breguet condenser pump previously described in the Engineering Survey.

The stresses in digester shells have been investigated by H. O. Keay, Mem.Am.Soc.M.E. These stresses are of interest because, in the case of a digester in addition to the pure steam stresses, the effect of the heavy masonry present has also to be considered.

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

Engineering Materials

STRUCTURE OF CAST IRON IN METAL MOLDS, Edwin F. Cone

A discussion of the structure of cast iron in metal molds as compared with that in sand molds.

That there must be a decided difference between the microstructure of cast iron cast in sand molds and cast in a metal mold, especially a rapidly revolving one, is evident. This matter becomes of particular importance as it has been demonstrated that it is possible to make cast-iron pipe in rapidly revolving molds.

Metal-mold pipe is manufactured by pouring hot metal into a rapidly revolving mold and removing the casting as soon as it has become solid. Under these conditions the crystal formation proceeds in a different manner from that in sand-cast pipe where the crystals are given time to develop slowly.

An examination of samples of the two types of pipe have shown that in the case of the chilled pipe the sample does not represent the chill, but only the average of nearly the entire metal section. Comparing the machine-cast with the sand-cast pipe samples, it is noticeable that the combined carbon is less, due to the amount of pearlite present caused by the conditions of cooling.

A comparison of the photomicrographs of the two types of metal given in the original article tends to indicate the superiority of machine-cast metal from the point of view of crystalline structure. The crystals are smaller and more closely knitted together, while the graphite is in smaller flakes and not in long plates. (*The Iron Age*, vol. 100, no. 12, September 20, 1917, pp. 656-658, 18 figs., *ec*)

EXPERIMENTS ON THE FATIGUE OF BRASSES, Dr. R. Archer Haigh

Description of an extensive series of experiments the purpose of which was to ascertain the effects of annealing, using stresses alternating between equal intensities of direct pull and push; to ascertain the relation between the limiting range of stress required to produce fatigue and the ratio between the maximum and minimum stresses; to study the phenomena of elongation under stresses greater than the fatigue limit but less than the ultimate tensile strength of the material; and, finally, to study the influence upon the endurance of the metal under the alternating stresses of corrosive reagents in contact with the metal.

The paper describes the method of testing and the machine used. The brasses used in these experiments were obtained from commercial supplies and not specially manufactured for the purpose.

The data are given in the form of tables and curves. The most interesting part of the investigation refers to the alternating-stress tests.

It was found that under alternating stresses varying between

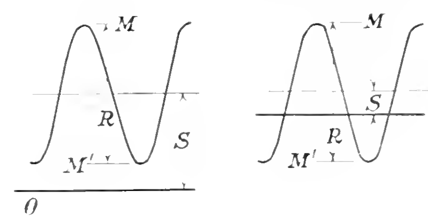


FIG. 1 DIAGRAM OF STRESSES IN A SPECIMEN TESTED IN AN ALTERNATING STRESS-TESTING MACHINE

equal intensities of pull and push with a frequency of 2000 per min., the behavior of these brasses was very similar to that of mild steel tested in the same manner. The limiting fatigue stresses were, however, somewhat lower and the results, in general, somewhat more consistent between different specimens of the same sample; likewise, the fractures were, as a

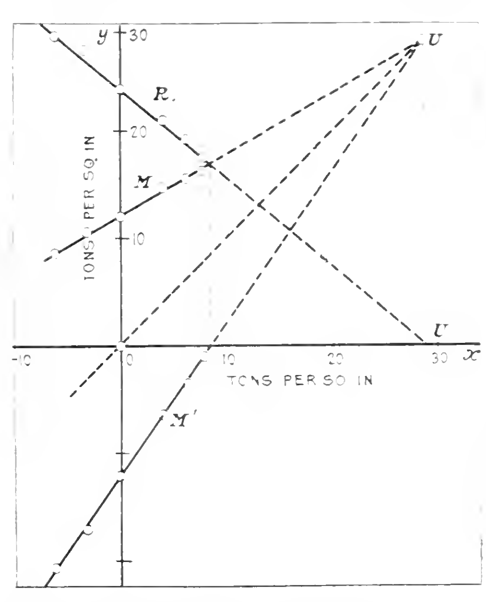

FIG. 2 FATIGUE LIMITS UNDER UNEQUAL PULL AND PUSH

[illegible] more regular in profile. One of the interesting features observed in considering the microstructure of brasses was that the cracks produced in brasses of sound structure showed the "branch" that are commonly observed in mild steel. Further, it was found that under test conditions the growth of the crack was exceedingly rapid. That this is not so in practice may be due to the variability of the stresses at work.

Among other things it has been found that there is no direct proportionality between the limiting fatigue and the primary elastic range in tension and compression. On the whole, the most regular ratio of comparison appears to be the ratio between the limiting fatigue stress and the ultimate strength of the metal. Further, the use of this ratio has the advantage of conveying useful information without implying the existence of any definite physical relation between the two quantities.

The experiments are claimed to illustrate, although they cannot prove, a simple working rule which seems to have few exceptions, namely, that the value of the ratio between the limiting maximum stress for 1,000,000 cycles and the ultimate tensile strength of the metal is highest for those metals which show considerable reduction of area at fracture in the tensile-strength test. It is not intended to imply, however, that a physical connection exists between the two, except in so far as both may be dependent on the same characteristics of the micro- and submicro-structure.

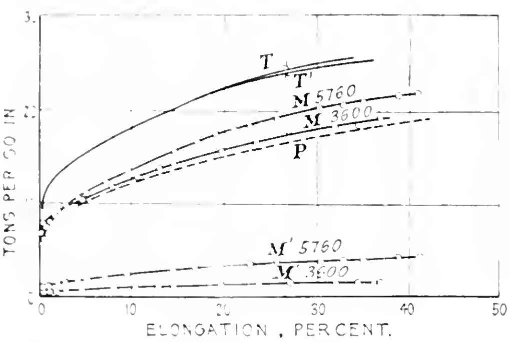

Fig. 3 Ductile Elongation of Brass Wire Under Alternating Stresses

A series of tests was made to ascertain the relation between the limiting fatigue range and the ratio between the unequal maximum intensities of direct pull and push. The curves obtained, as, for example, in Fig. 2, were found to be asymptotic to values which may be regarded as nearly equal to the fatigue limits below which fatigue would not occur after an infinite number of repetitions of stress. In Fig. 2 the abscissæ give the mean stress, and the ordinates for graph R the limiting fatigue ranges, and for graphs M and M' the maximum intensities of pull and push. It appears that plotted in this manner the stresses obey the linear law which may be expressed as

$$R = R_0 - k\,S$$

$$M \text{ or } M' = (S \pm \tfrac{1}{2} R) = S \pm \tfrac{1}{2}(R_0 - k\,S)$$

The graphs M and M' represent here the limiting conditions of stress above which fatigue occurs by the production of a brittle fracture, but when the range of stress is greater than that represented and is combined with considerable steady pull or push, failure may also occur by the gradual elongation or compression of specimen. The same material was tested under pulsating stresses with frequencies of 5700 cycles and 3600 cycles per min. Here again the yield point was observed to be somewhat indefinite, but above the yield point elongation was produced at definite stresses lying within limits of measurement.

In Fig. 3 the maximum and minimum intensities M and M' are plotted on the base of elongation used for the tensile tests, Fig. 1. Comparing the curves, it seems at first sight that the change in frequency has produced considerable effect, but the difference between the maxima for the two frequencies may be attributed to the differences betwen the two minima employed. By varying the minimum while the test was in progress, it was found that any given increment to M' required a corresponding but similar increment to M to produce elongation. Careful measurements showed that increment to M was from one-half to one-third of that to M'. Assuming either of these values, one may deduce from M and M' the value of an "equivalent" pulsating stress which with zero as the minimum of its cycle would produce the same elongation. The approximate locus of this "equivalent" pulsating stress is represented in the diagram by the curve P, somewhat below M. The ordinates of P are nearly alike for tests with the different frequencies and are approximately two-thirds of those of the curves representing the tensile tests.

Similar tests have been carried out on soft copper wire. It was found that although the yield point under pulsating stress is nearly equal to that under steady tension, further elongation is produced with considerably less increase of load than in an ordinary tensile test; also that the ultimate elongation produced in copper is considerably greater under pulsating stress (46 per cent) than under steady stress on the same material (34 per cent).

Further experiments have shown that the nature of the elongations is the same no matter whether produced by a pulsating or steady stress. Another interesting fact which has been brought out by the tests is that although some 500,000 cycles of stress were imposed on individual specimens in the course of the elongation tests, no examples of brittle fatigue were found, except in rare instances at the end attachments. It may be inferred that if the range of stress is less than the maximum tension (80 to 90 per cent) the fatigue limit lies above the yield point for pulsating stress. In practice the actual range at particular points in a complex structure may, however, be greater than the mean range is generally estimated, so that fatigue may occur although the estimated range is well below the maximum tension.

An interesting series of tests was carried out for the purpose of ascertaining whether fatigue was accelerated by the presence of different corrosive fluids in contact with the metal during the test. On the whole, it was found that no appreciable acceleration of fatigue had been produced by any of the corrosive reagents employed. On the other hand, it is believed that fatigue may vary readily in parts that have suffered appreciable corrosion prior to the application of the stresses that effect the failure. The phenomena occurring in specimens tested under alternating stresses may differ, however, from those of normal corrosion, in that they occur only locally and with much greater rapidity. Chemical action is certainly accelerated by strain in the crystals even below the elastic limit: and the elongation of stress facilitates the formation of crevices and progressive corrosion throughout the mass. It appears also that the atmosphere as well as fluid reagents may act chemically upon the metal. (Paper read before the Institute of Metals, September 19, 1917, abstracted from a reprint in *The Engineer*, vol. 104, no. 2699, September 21, 1917, pp. 315-319, 23 figs. *eA*)

Fuel

PULVERIZED FUEL IN A POWER PLANT ON THE MISSOURI, KANSAS & TEXAS RAILWAY, R. H. Collins and Joseph Harrington, Mem.Am.Soc.M.E.

Description of a plant burning pulverized coal under boilers and of tests thereon, the latter including data on the method used in weighing coal which are of interest.

The data of the tests are given in the form of tables. Of particular interest is the heat balance. The boilers were found to be quite efficient under the conditions of the test, and the furnace and grate extremely so (Table 1), no loss being shown as due to combustible in the ash. The ashpit in this case had a sloping bottom and was visible throughout its extent from the door in the basement. The ash mostly fused and ran down the bottom in molten streams. Practically no dust in the ashpit was encountered, while under the ordinary operating conditions in this plant with the same fuel and operating at times at low ratings there is produced a mixture of fine sandy-looking ash and melted slag.

TABLE 1 DATA OF TESTS OF A POWDERED-COAL-FUEL INSTALLATION FOR STEAM GENERATION ON THE M. K. & T. RR.

FURNACE AND GRATE LOSSES	B.t.u	Per cent	B.t.u.	Per cent	B.t.u	Per cent

Combined efficiency........	..	57.32	......	58.00	....	69.64
Ratio: Comb. effy. to highest theo. efficiency.......................	..	64.80	....	63.90	.....	75.49

During the tests there was a light gray haze apparent at the top of the slag. A sample of this dust was obtained from the breeching. Analysis showed that there was 2 per cent of combustible matter in the fine dust, which showed that the loss in this item was exceedingly small.

Another matter worthy of attention is the item of heat absorbed by excess air. The CO_2 content in the flue gases could without the slightest difficulty be carried up to 16 per cent, readings frequently going to 17 per cent and but few readings being less than 15 per cent. It was found that the CO loss was in direct proportion to the length of the flame, which indicates some relation between the proportion of volatile matter in the fuel and the CO loss.

The furnace conditions in this case were as nearly ideal as one could imagine. The unaccounted-for loss in this test is also the least and the furnace efficiency the greatest.

The question of control of the furnace temperature and consequent fusing of the brick walls has been hitherto a mooted point in connection with the burning of powdered coal under steam boilers. In this instance careful measurements checked in several ways have shown that the temperature of the furnace was between 2300 and 2400 deg. fahr., under which conditions brickwork may be maintained indefinitely, and which is above the fusing point of the ash from a great many coals. Actually, there was no apparent fusing of the brickwork, which might occur if the ash had a fluxing effect thereon. The furnace has been in constant service for nine or ten months and the interior seems to be in perfectly good shape.

On the whole, the writer believes that these tests give promise of a future for powdered coal in steam generation which is indeed bright. It is possible to burn in this way qualities of coal which are not ordinarily classed as of commercial value. Moreover, it is entirely possible to provide space adequate for the complete combustion of fuel in this form and control the temperature of the furnace properly. Hydraulics

THE EFFECT OF MOUTHPIECES ON THE FLOW OF WATER THROUGH A SUBMERGED SHORT PIPE, Fred B. Seely

Data of experiments on the flow of water through a submerged short pipe with and without entrance and discharge mouthpieces of a variety of angles and lengths. This investigation treats of the loss of head which occurs when a stream contracts or expands under differing conditions of flow and emphasizes the marked effect that turbulence of flow may have upon the amount of head lost. The discussions have a direct bearing upon various problems in hydraulic practice which involve the contraction and expansion of stream in flowing through passages.

Comparatively little experimental work has been done to determine the value of conical mouthpieces of various angles and lengths in reducing the lost head at the entrance to and discharge from a submerged pipe, particularly for mouthpieces of the sizes and proportions comparable with those met in engineering practice.

The loss of head due to the contraction and expansion of a stream may be of considerable importance in a variety of hydraulic problems: for example, the passages through a large valve, the passages through locomotive water columns, the draft tube to a turbine, the connection from a centrifugal pump to a main, the venturi meter, the suction and discharge pipes of dredges and the guide vanes and runner of a turbine.

Losses due to this cause are difficult to estimate and easy to overlook. Even where such losses are, in themselves, of little consequence as compared with other quantities involved, they may have a considerable influence upon subsequent losses on account of the turbulent motion started by the contraction or expansion, and the writer cites several instances where this apparently takes place.

In the present investigation the values of the coefficients of discharge for the short pipe with inward-projecting entrance (no mouthpiece attached) were determined with special care since the effect of attaching the mouthpiece could not otherwise be found. The values found for c are slightly larger than those generally given in textbooks, while the values for m are considerably smaller. This may, however, depend on various concomitant factors.

To illustrate the method of handling the various important

problems of this investigation an abstract will be given of the part relating to entrance mouthpieces. From Fig. 4 it will be seen that entrance mouthpieces having angles of from 10 deg. to 30 deg. (20 deg. to 60 deg. total angle of convergence) give practically the same discharge, while all the entrance mouthpieces having angles of from 5 deg. to 60 deg. give only about 5 per cent range in the rate of discharge. In other words, the lost head at the entrance to an inward-projecting short pipe may be reduced from 0.62 of the velocity head in the pipe to 0.18 of the velocity head by a conical mouthpiece having an angle ranging from 10 to 30 deg.

It has also been found that no advantage results from increasing the length of the entrance mouthpiece beyond that corresponding to an area ratio of from 1 to 2. The lost

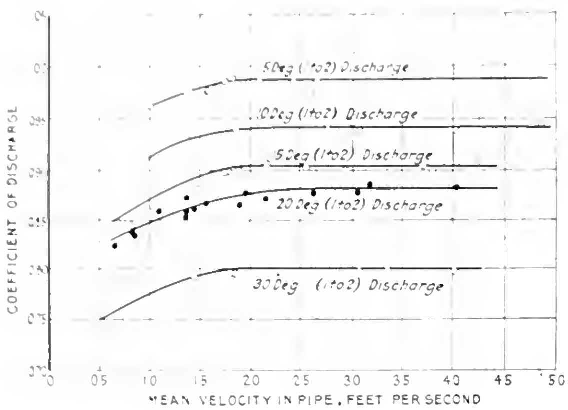

FIG. 4 RELATION BETWEEN COEFFICIENT OF DISCHARGE FOR A SHORT PIPE WITH MOUTHPIECE AND THE MEAN VELOCITY IN THE PIPE

head at the entrance to a mouthpiece is sometimes considered the same as would occur at the entrance to an inward-projecting pipe of the same area as that of the mouthpiece, that is, the lost head is found by multiplying the velocity head at entrance to the mouthpiece by the coefficient for an inward-projecting pipe. The writer does not approve of such a method, since the entrance mouthpiece having an area ratio of 1 to 3 gives almost the same lost head as one with an area ratio of 1 to 2, while the velocity head at entrance to the former mouthpiece would, of course, be only one-ninth of that of the latter. It is not clear just what effect straight throat or pipe has when added to an entrance mouthpiece.

Owing to lack of space only the most important conclusions of the present investigation can be reproduced here.

a As applying to conditions likely to be met in engineering practice, the value for the head lost at the entrance to an inward-projecting pipe (i. e., without entrance mouthpiece and not flush with wall of the reservoir) is 0.62 of the velocity head in the pipe ($0.62v^2/2g$) instead of $0.93v^2/2g$, as usually assumed. To put it in another form, the coefficient of discharge for a submerged short pipe with an inward-projecting entrance is 0.785 instead of 0.72, as given in nearly all books on hydraulics. Further, the lost head at the entrance to a pipe having a flush or square entrance is 0.56 of the velocity head in the pipe ($0.56v^2/2g$) instead of [illegible], as usually assumed. In other words, the coefficient of discharge for a submerged short pipe with a flush entrance is [illegible] instead of 0.82 as given by nearly all authorities.

b The loss of head resulting from the flow of water through a submerged short pipe when a conical mouthpiece is attached to the entrance end may be as low as 0.165 of the velocity head in the pipe ($0.165v^2/2g$) if the mouthpiece has a total angle of convergence between 30 to 60 deg. and an area of ratio of end sections between 1 to 2 and 1 to 4 or somewhat greater. In other words, the coefficient of discharge for a submerged short pipe with an entrance mouthpiece as specified above is 0.915.

c The loss of head which occurs when water flows through a submerged short pipe having an entrance mouthpiece varies but little with the angle of the mouthpiece if the total angle of convergence is between 20 and 90 deg. and if the area ratio is between 1 to 2 and 1 to 4 or somewhat more. The loss of head for any mouthpiece within this range would be approximately 0.20 of the velocity head in the pipe ($0.20v^2/2g$). There is, therefore, little advantage to be gained by making an entrance mouthpiece longer than that corresponding to an area ratio of 1 to 2. Thus, an extrance mouthpiece with a total angle of convergence of 90 deg. and the length of which is only 0.2 of the diameter of the pipe gives approximately $0.20v^2/2g$ for the loss of head.

d The amount of velocity head recovered by a conical mouthpiece when attached to the discharge end of a submerged short pipe depends largely upon the angle of divergence of the mouthpiece, but comparatively little upon the length of the mouthpiece. This is true for lengths greater than that corresponding to an area ratio of 1 to 2 and for total angles of divergence of 10 deg. or more. The amount of velocity head recovered decreases rather rapidly as the angle of divergence increases from a total angle of 10 to 40 deg. At or near 40 deg. the amount of velocity head recovered rather abruptly falls to approximately zero.

e A conical discharge mouthpiece having a total angle of divergence of 10 deg. and an area ratio of 1 to 2, when attached to a submerged short pipe, will recover 0.435 of the velocity head in the pipe, which is 58 per cent of the theoretical amount possible of recovery.

f The amount of velocity head recovered by a diverging or discharge mouthpiece when attached to a submerged short pipe is considerably more when a converging or entrance mouthpiece is also attached than it is when the entrance end of the short pipe is simply inward-projecting (no mouthpiece attached). This excess in the velocity head recovered diminishes rather rapidly as the angle of discharge mouthpiece increases, and it becomes zero for a discharge mouthpiece having a total angle of divergence of approximately 40 deg. This increase in the velocity head recovered is probably due to the effect of smooth flow in the pipe as the water approaches the discharge mouthpiece. The smooth flow allows the mouthpiece to recover more of the velocity head in the pipe than when a more turbulent flow exists; this increase amounts to as much as 33 per cent in the case of the discharge mouthpiece having a total angle of divergence of 10 deg. and an area ratio of 1 to 2. (*University of Illinois Bulletin,* vol. 14, no. 35, April 30, 1917, 48 pp., 14 figs., *eA*)

Internal-Combustion Engineering

VICKERS SYSTEM OF SOLID INJECTION FOR DIESEL ENGINES

It has been mentioned in the engineering papers that Vickers, Ltd., of Barrow, have been using solid injection of fuel with their four-cycle type submarine Diesel engines. This system enables them to dispense with high-pressure injection air, but has the disadvantage of giving a higher fuel consumption, sometimes as high as 10 per cent in excess of that required with good air-injection systems.

In view of the secrecy hitherto maintained about this system, the following data taken from a British patent are of interest:

The fuel is delivered by a pump *M* (Fig. 5) giving constant fuel pressure, and the power of the engine is controlled by varying the period of opening of the injection valve *G* by an adjustable lever *J* operated by a cam *H*, the shape of which is so related to path given to the end of the lever by the adjustment that for all adjustments and consequent variations in engine power the valve is timed to open at the correct point at which injection should take place. Independent timing means are therefore dispensed with, the cam being formed to give the proper timing for the operation of the valve for all variations in the period of opening.

The pump is of a larger capacity than is required by the engine, and surplus fuel is discharged through the adjustable relief valve. The control of the suction of the pump, however, allows the output of the pump to be regulated as the power of the engine is varied. Excess fuel is always delivered by the pump, so that the pressure to which the relief valve is adjusted is maintained. But the excess over that required by the engine is kept approximately constant, thus assisting the

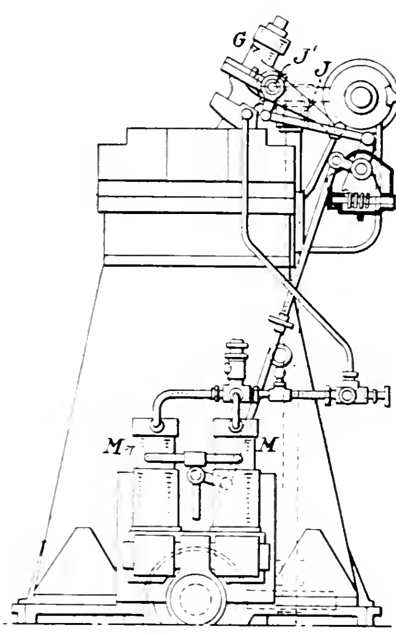

Fig. 5 Vickers Method of Solid Injection of Fuel for Diesel Engines

relief valve to maintain a steady pressure. This connection to the fuel pump is particularly desirable for constant-speed engines; for example, those driving dynamos, in which the surplus to be passed by the relief valve would otherwise be greatly increased while running at light loads. Machine Shop

Relation of Press Stroke to the Life of a Die. E. F. Creager

The writer attempts to answer the question as to whether a short stroke that is less than standard increases the life of punch and die. He made some experiments and found that decreasing the stroke of the press increases the life of punch and die.

The work the writer was engaged in was that of punching armature laminations. With a "solid" type of punch and die made from the best steel available, the production between grinds was on an average of from 12,000 to 15,000 blanks, both figures with the standard $2\frac{1}{2}$- and 3-in. strokes. Next the same punch and die set was transferred to a press with a $1\frac{1}{2}$-in. stroke and immediately it gave 40,000 blanks before the fin was as bad as it was in the longer-stroke press at 12,000 to 15,000 pieces. At the same time it was found possible to double the output from the same set of dies while maintaining a higher standard of product.

This is a very important saving, considering the fact that it takes from 67 to 76 hours to make the punch, while the completed die mounted for the press takes 270 hours. There are also other savings from the longer life of the punch and die besides those mentioned above.

The article also discusses some of the details of press con-

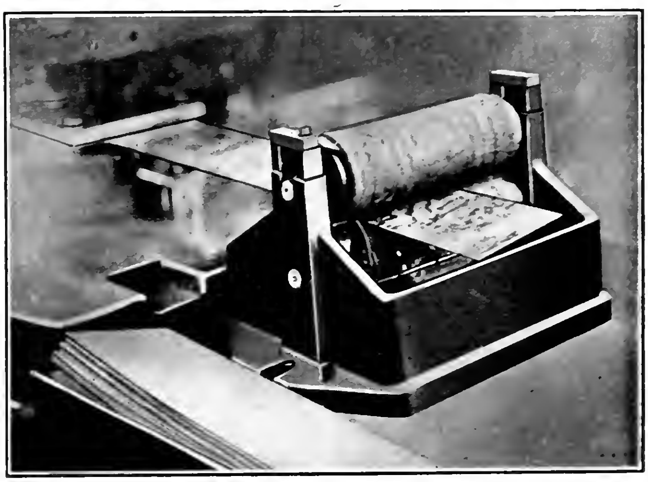

Fig. 6 Steel-Strip Oiling Device

struction. For example, the fact is mentioned that it would not cost much to secure the key in the brake wheel, and still the writer has seen at least two accidents caused by the key dropping out and allowing the release to strike the stop pin hard enough to break it off and permit the press to repeat. The proper way is to drill and tap the brake wheel over the key and countersink the key slightly, then use two headless set screws, one acting as a lock.

The writer also thinks that the many unnecessary bends on the pedal rod in some presses and its general flimsiness in others are the wrong way to economize. All presses should be supplied with the non-repeat trip that can be used or not, as desired, and all presses should be guarded at the crankshaft where it approaches the cam.

Fig. 6 shows a simple, little-known device for oiling the strip before punching. Formerly three men with brushes did this work. Now one operator does it with no decrease of speed, no increase of cost, and a saving of approximately 60 per cent of oil.

The writer also recommends a motor-driven shear roll grinder to grind the cutters in position.

It will greatly reduce the twist in the sheet and facilitate handling in the press, if care is used in setting the cutters for depth so that they will shear instead of tear. Cutters ground in position will last five times as long between grinds and the total life will be at least as much longer. (*American Machinist*, vol. 47, no. 12, September 20, 1917, pp. 485-487, 7 figs., *dp*)

Mechanics

On the Whirling Speeds of Loaded Shafts, W. M. Wallace

Details of experiments arranged for the purpose of examining (1) the accuracy of various simple methods of determining the whirling speed of a shaft of variable sections, and (2) the effect of radial clearance at the bearings on the whirling speed.

A previous article (*The Engineer*, June 16 and 23, 1916, compare The Journal, August 1916, p. 673) indicated a graphic method of estimating the whirling speed of a symmetrical shaft loaded at the middle with a single disk load. In this simple case there was, of course, no appreciable gyroscopic action on the shaft. In the present case the test was made with two similar cast iron disk loads, fixed symmetrically on the shaft in the positions shown in Fig. 7. The shaft was supported at the sections *A*, *A* by simple cast iron bearings, so arranged that the surface of contact of shaft and bearing was limited to a ring of 1/4 in. breadth, and, as the shaft was a nice turning fit in this ring, the positions of the nodes were known almost to one-eighth of an inch.

In Fig. 7 the bending-moment diagram for the loaded shaft is shown by *a b c d*, and the diagram reduced to suit the similar section of the shaft in *a e f g h l m n r d*: the deflection diagram (only half of which is shown) is *p e t*.

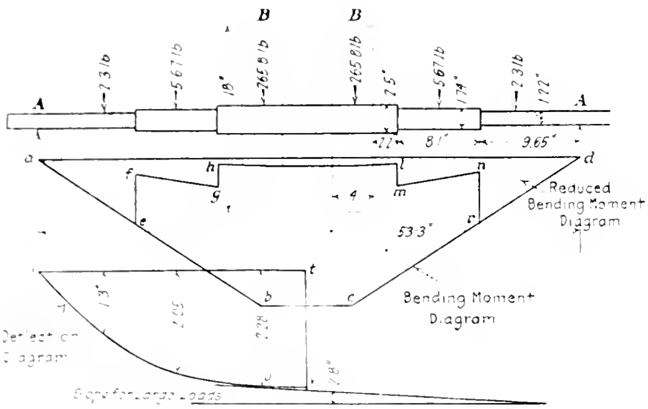

FIG. 7 BENDING-MOMENT AND DEFLECTION DIAGRAMS OF A SYMMETRICAL SHAFT OF VARIABLE SECTION, FREELY SUPPORTED ON RING BEARINGS AND LOADED WITH TWO CAST-IRON DISKS *B B*

The writer makes the calculation in detail, and shows that when working with four-figure logarithmic tables no appreciable difference is seen in the results, as far as gyroscopic action is concerned.

When this shaft was actually running, it commenced to whirl at 663.6 r.p.m., and continued until a speed of 680 r.p.m. was reached; the maximum whirl appears to have occurred at a speed of 677 r.p.m. The calculations carried through by the author indicate that the whirling speed, with gyroscopic action neglected, should have occurred at 687.5 r.p.m., or about 1.5 per cent above the speed actually found by experiment. This difference may be due to experimental error, or, more probably, to the slight difference in diameter of shaft and bearing, a difference which must always occur where a shaft turns freely in its bearing.

The writer checks these figures by a rapid approximate method, using the deflection tables for a uniform shaft, previously described in *The Engineer*, and finds a value for the whirling speed for the shaft of variable section shown above of 665 r.p.m. Since, however, this method is known to tend to give results on the high side, it appears that the correct theoretical whirling speed is about what the graphical method indicates, or 688 r.p.m.

An interesting feature of these experiments, both with and without bearing clearance, was the difficulty experienced in obtaining a true whirl of the shaft. Under the action of hammer blows along the line *X-X*, Fig. 8, the cast-iron stands which are fixed at the base to a massive iron bed yield slightly, with the result that on speeding up the shaft horizontally, vibrations first made their appearance, which died down as the speed was increased, to be succeeded by vertical vibrations. This experience suggests the possibility that as soon as it is unlikely that the clearance and yield of bearings is rarely the same in these two directions, the shafts of most machines do not whirl at any speed, especially if the noise produced is considerable.

A series of tests was also carried out in order to determine the effect of radial clearance by the bearings on the whirling speed. To do this the shaft was dismounted and the ends turned down at the sections of support *A*, as shown in Fig. 9, so as to form a diametral clearance of 0.044 in.

A simple theory offered in *The Engineer*, September 1, 1916, anticipated that the clearance would lower the whirling speed and increase the range of speeds over which whirling would occur.

Figs. 10 and 11 may be used to explain the leading lines of this theory. Here the exceptionally thin shaft is shown whirling with the radial clearance β at the bearings. The deflection of the shaft at any given point being y, the potential or strain energy stored in the shaft is proportional to y, but the radius of the circle of whirl described by the shaft at this point being

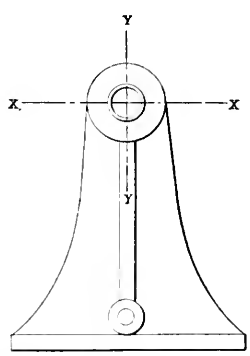

FIG. 8 BEARING FOR SHAFT SHOWN IN FIG. 7

$y+\beta$, it follows that the kinetic energy of motion is proportional to $(y+\beta)^2$; that is, instead of using the summation of Wy^2 in the denominator of the experiment for N, it is necessary to use the summation of $W(y+\beta)^2$. This, of course, results in a lower value of the whirling speed being obtained.

The writer points out that not only are the magnitudes of the out-of-balance force on the shaft important in affecting the speeds and the amplitudes of vibrations or whirl, but that their disposition on the shaft is also of importance. In most cases in practice, it is a single force situated near the middle of the shaft, a case for which the simple theory indicated above is applicable; still, it is easy to conceive a case in which the clearance effect would only be realized upon end of the bearing.

The writer further claims that the more one studies the actual behavior of shafts, the more one realizes how inadequate, even misleading, is the usual mathematical treatment of the problem.

The calculation given by the writer indicates that disturbances should begin at 531.1 r.p.m. On actually running the shaft, horizontal disturbances commenced at about 500 r.p.m. There is reason to believe that this very low speed was due to the yield of the bearings in a horizontal direction. The hammer blows along the line X-X, Fig. 8, have a considerable leverage over the bases of the supports; whereas, the forces along the line Y-Y have no such leverage.

The vibrations in a vertical direction commenced and finished at speeds which depended upon whether the speed of rotation was being increased or decreased. On being increased they commenced at 650 r.p.m. and ceased at 680 r.p.m. On coming down they commenced at 650 r.p.m. and ceased at 570 r.p.m. From this data it appears that 570 r.p.m. is the lowest speed at which the vertical forces can maintain (not originate) a rhythmic lifting of the shaft through the clearance distance; that when a disturbance has once been set up it is continued to speeds far beyond those which can be established when the speed variation is in the opposite direction. There is no true whirl, because the maximum vertical disturbance does not occur with the maximum horizontal disturbance.

The writer emphasizes the fact that there is what one might call a certain difference in conception between the mathematical view of critical speeds and what is found in actual practice. The usual mathematical solution gives one the impression that there are certain speeds at which the shaft is in a state of instability so highly sensitive that any slight lateral disturbance would cause a catastrophe. This hypersensitive state exists only in the minds of the mathematicians. Actually, there is a certain range of speed over which the shaft is most

sensitive to out-of-balance force, but by reducing the out-of-balance force sufficiently it is possible to run a shaft quite safely at any speed. (*The Engineer,* vol. 124, no. 3221, pp. 246-247, 7 figs., *et*)

Disk-Wheel Stress Determination, S. H. Weaver, Mem. Am.Soc.M.E.

Reproduction of the paper presented by the writer at the Spring Meeting of The American Society of Mechanical Engineers in May 1917.

In addition to the data presented in the paper before this Society are given several charts for facilitating the derivation of tangential stresses as given in Equations 5a and 5b in the paper. (*General Electric Review,* vol. 20, no. 10, pp. 791-799, illustrated. The charts are on pp. 794-798. *tA*)

Motor Trucks

The Building of the U. S. Military Truck

An announcement was made October 8 to the effect that the first Liberty motor truck for the U. S. Army had been completed at Lima, Ohio.

The Liberty motor truck was built in great secrecy. A building without windows and lighted only by skylights housed the truck during the three weeks of its construction. The plant was closely guarded by armed men night and day.

The parts were manufactured elsewhere and as each part was completed it was dispatched to Lima in charge of an army representative, who kept factory officials informed of his progress by telegraph. No one company knows the complete design, or what other companies in various parts of the country made other parts.

In view of this statement officially given out to the daily press, the following data published by the Society of Automotive Engineers become of interest.

The standardized military truck for the U. S. Army was

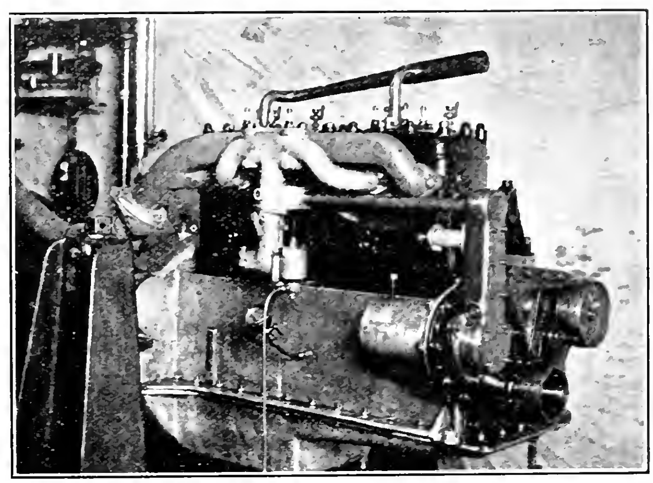

Fig. 12 Liberty Truck Engine

built under the supervision of the Quartermaster Department, Col. Chauncey B. Baker and other officers, with the collaboration of engineers of the various companies.

As regards the engine, it was at first intended to have two types of engines, class A and class B, but it was found that a consistent design of the latter would only be 120 lb. heavier than the design suggested for the former. It was therefore decided to standardize one model for use on both sizes of military truck, the only difference in the two engines being in the bore. It will thus be possible to decrease greatly the number of repair parts needed for the two engines.

The fuel tank will be located on the dash, with provision for a surplus under the seat.

As regards the lubrication system, it was found that the amount of oil passing per unit of time is the determining factor and that this is practically equal in a number of systems operating at widely different pressures. It has been decided to adopt the full-pressure feed with the relief valve at the end of the system. In order to always have the oil in the best possible condition, a method of cleaning it has been developed consisting of passing the oil through a large screen and in having three settling chambers.

The intake and exhaust manifolds of the engine are designed so that heavy gasoline will be thoroughly vaporized. In fact,

it is said that the engine could be operated on kerosene with only minor changes in manifold design.

The transmission is of the four-speed horizontal type and located amidships. Four universal joints will be used in the drive, two between the clutch and transmission and two between the transmission and rear axle. In the design of transmission special care has been taken to secure maximum accessibility and ease of replacement. For instance, only 5/8-in. plugs are used for fastening the covers and bearing retainers. On the right-hand side a handhole has been supplied for inspection purposes.

The truck will have two independent ignition systems for two separate sets of spark plugs. The ignition will be controlled by one switch, so that both ignition systems are either in the "on" or "off" position. A special switch has been designed which carries the lighting and ignition switches and also the ammeter and cowl lamp. The circuit breaker is to be mounted on the back of this switch. The generator is of the third brush type, normally giving eight amperes at 750 r.p.m. It is driven by an Oldham coupling.

As regards the rear axle on class B truck, it will be of the worm-gear type on account of the great manufacturing capacity available for producing the sizes of axle necessary for the heavy service. The class A truck will be equipped with an internal-gear axle. The worm-gear axle has been refined and simplified. For instance, only two sizes of roller bearings will be used instead of the five ordinarily required for the full-floating type of axle. The dry plate at the end of the axle is held by bolts instead of studs, as is the usual practice.

As regards production, it is understood that no employee will be engaged without the full approval of the Quartermaster General's Department after consideration of statements as to nationality and former connections. The men who will handle the production work are really drafted for the national service just as much as those who have joined the National Army. But they will carry the work on in the same manner and by the same methods which made them successful in private business.

In working out the design of the Liberty motor truck the Quartermaster Department had the great advantage of the most hearty coöperation on the part of private companies and the Society of Automotive Engineers.

Two experimental units have been completed, and since formally delivered to the Secretary of War in Washington.

For further details so far published in connection with the design of the Liberty motor truck, the readers are referred to the *Journal of the Society of Automotive Engineers*, vol. 1, no. 3, September, 1917, pp. 173-177.

Pumps

TESTS OF A ROTARY AIR PUMP

Data of tests carried out by Professor Trinks of the Carnegie Institute of Technology on a small Roots pump.

The purpose of the tests was to determine how much air the pump could handle. The air admitted to the pump was caused to pass, previous to entering it, through two tanks, which makes a somewhat cumbersome but necessary arrangement. The reason for this procedure is as follows: If the air going through the pump had been admitted directly through the nozzle at the pump inlet, the pulsation at the pump would have caused the nozzle to show a greater quantity of air flowing than actually did flow. The tanks themselves and the thin rubber diaphragm provided in one of them entirely eliminated these vibrations.

In order to duplicate as far as possible the conditions existing in heating service, the pump in the test was supplied with a small amount of water for sealing purposes. At first the action of the pump was found to be very erratic as it would ultimately hold and lose the vacuum, but it was later found that the trouble lay in the surging back and forth of the sealing water. A check valve was placed in the suction line near the pump and the trouble immediately disappeared. This surging never occurs in practice, because a check valve is usually present.

The more water was admitted the higher was the vacuum which could be maintained by the pump.

Fig. 13 indicates the quantity of air determined by the vacuum which can be maintained by the pump. It expresses

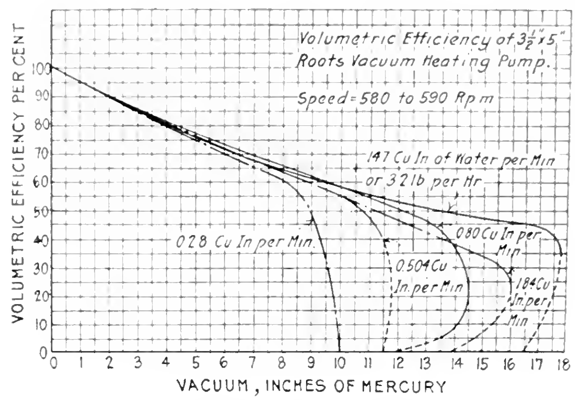

FIG. 13 QUANTITY OF AIR HANDLED BY SMALL ROOTS PUMP DETERMINED BY THE VACUUM ON THE PUMP

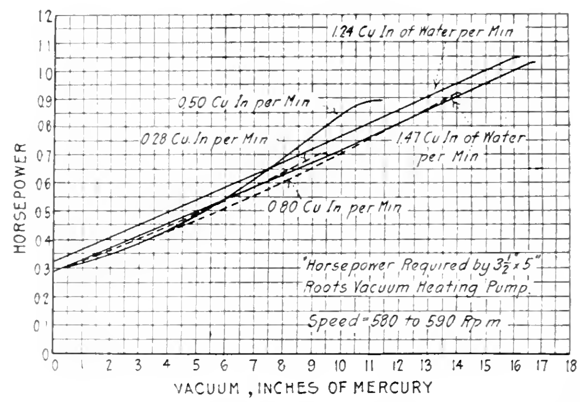

FIG. 14 POWER CONSUMPTION OF A SMALL ROOTS PUMP UNDER VARYING CONDITIONS

the volumetric efficiency of the pump as a function of the vacuum (hence of the quantity of sealing water). By volumetric efficiency is meant the ratio in per cent of the quantity of air actually delivered to the quantity which would be delivered under ideal conditions.

Fig. 14 shows the power consumption of the pump under different conditions, again as a function of the vacuum. It appears that the power varies in a straight line with the vacuum. An operator can considerably increase the power consumption by tightening the stuffing boxes. (*American Gas Engineering Journal*, vol. 107, no. 14/3109, October 6, 1917, pp. 301-302, 3 figs. *e*)

Recent Developments in Air-Pump Design, E. Jones

Discussion of the merits of some of the more recent developments in design of air pumps used as auxiliaries to steam machinery.

The writer discusses the comparative merits of the five standard types of condensers, namely, evaporative, ejector, barometric, jet and surface, with particular reference to the latter two. In this connection he gives a table (Table 2) showing the relative costs and requirements of barometric, jet and surface condensers. The conditions which have been assumed are the same for each case, namely, steam quantity, 40,000 lb. per hour; vacuum with barometer at 30 in., 28½ in.; cooling water at 60 deg. fahr.; and for prime mover a high-pressure steam turbine. Under the present abnormal conditions surface condensers are in a particularly unfortunate position, owing to the cost of the materials used for tubes and tube plates, which is approximately 27½ per cent of the value of the whole equipment.

Of the particular designs discussed by the writer, the Breguet condenser is of special interest. It was introduced

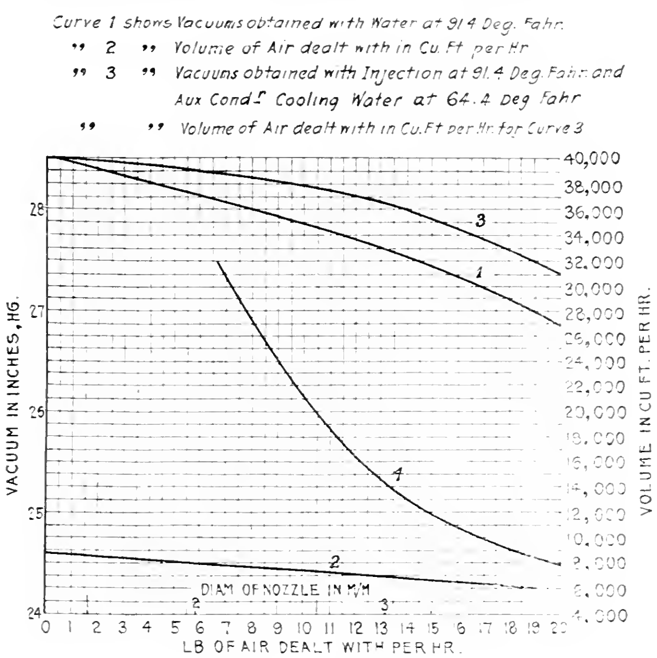

Fig. 15 Breguet Ejectair Theoretical Vacuum at 91.4 Deg. Fahr.

just before the war, and is now said to be extensively applied in the French navy. A description of it was given in The Journal, 1914, p. 0183. These "ejectairs," as they are called, are designed for working with steam pressures at 55 lb. per sq. in. or above, and with the special arrangements of nozzles lower pressures can be used in the primary ejector.

The curves, Fig 15, show the performance of an ejectair. Steam to the ejectors had an absolute pressure of 125 lb. per sq. in., and the steam consumption is given at 194 lb. per hour, of which 129 lb. are recoverable. The apparatus worked in conjunction with a small jet condenser, dealing with 94 gal. of injection water per min. Curve 1 gives the vacuums obtained with water leaving the condenser at a temperature of 91.4 deg. fahr. (33 deg. cent.), and the auxiliary condenser out of action; curve 2 the volume of air dealt with in cubic feet per hour; curve 3 the vacuums obtained with given air leaks, and the water leaving the main condenser as for cooling water at 66.2 deg. fahr. (18 deg. cent.); and curve 4 the vol-

TABLE 2 RELATIVE COST AND REQUIREMENTS OF BAROMETRIC, LOW-LEVEL JET AND SURFACE CONDENSERS

Type of Plant	Consisting of	Approximate Net Weight of Apparatus	Horsepower Required to Drive Condenser and Auxiliaries	Present-Day Costs	Equivalent Ratio

umes of air dealt with under the same conditions. It was calculated that the air coming in with the injection water and at leaky joints amounted to 1.102 lb. per hour, or 0.5 kg. (*Engineering*, vol. 104, no. 2697, September 7, 1917, pp. 263-265, 9 figs., first installment of a serial, *d*)

Railroad Engineering

The Shrinkage Allowance for Locomotive Tires, E. L. Ahrons

The writer compares the methods of determining shrinkage allowance on a large English main line with that adopted by the American Master Mechanics' Association and the one adopted by the Lancashire & Yorkshire Railway in England.

In the diagram, Fig. 16, the graphs give the immediate shrinkages for wheel centers of different diameters; A A being the curve for the large English railway, B B the American Master Mechanics' Association standard and C C that of the Lancashire & Yorkshire Railway.

The standard practice of the Great Northern was to allow a shrinkage of 1 in 800. Stress-strain diagrams made from tests of class C—British standard—tire steel of 50 to 55 tons ultimate tensile strength, showed that the elastic limit was reached with an extension of about 0.2 per cent, at 26.5 tons per sq. in. Therefore, an extension of 0.1 per cent, or 1 in 1000, results in a stress on the material of the tire of 13.25 tons per sq. in. The modulus of elasticity of this tire steel will therefore be 13,250.

The diameter of the wheel center was 74 in., and that of the tread of the tire, after shrinkage, where the measurement was taken, was 80 in., the tire being 3 in. thick. It was found that the outside perimeter had extended 0.232 in. after shrinkage on, with an allowance of 1 in 800 on the inside, i. e., on the diameter of the wheel center. The outer circumference, after shrinking, being 251.33 in., the original length of the circumference was therefore 251.098 in., and the strain e = 0.232/251.098. The stress in the outer fiber of the tire = 13.250 e = 12.242 tons per sq. in.

Treating the tire as a ring of rectangular section, and using

[illegible] in thick cylinders, and [illegible] 12.242 [illegible]

[illegible] of the tire [illegible] between tire and wheel center, [illegible] the hoop tension P and the radial stress [illegible] P [illegible] Q [illegible] P [illegible] Q [illegible] con[illegible], and since there is no radial pressure on the outside of the tire [illegible] 0, and therefore P [illegible] Q [illegible] P [illegible] 12.242 tons per sq. in.

On the inner fiber of the tire the usual form of Lamé's expression is

$$P_1 \quad Q_1 \frac{R \quad R^2}{R \quad R_1^2} \qquad \ldots\ldots\ldots\ldots [1]$$

in which R_2 and R_1 are the outer and the inner radii of the tire and P is the apparent hoop tension, neglecting the effect of lateral contraction (Poisson's ratio).

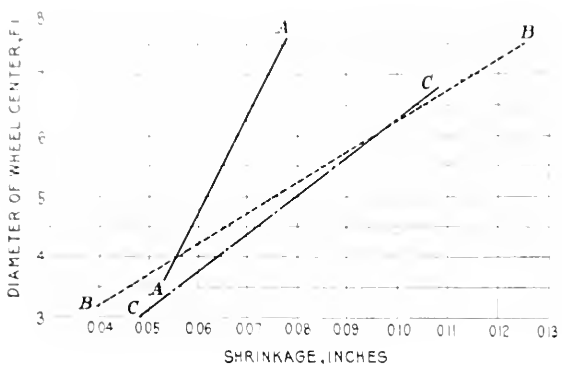

FIG. 16 COMPARISON OF THREE STANDARDS OF SHRINKAGE OF LOCOMOTIVE TIRES

Taking the effect of lateral construction into account, the stress equivalent to the greater strain is

$$P_1 = Q_1 \frac{R_2^2 + R_1^2}{R_2^2 - R_1^2} + \frac{1}{m} \qquad \ldots\ldots\ldots\ldots [2]$$

in which m may be taken as 3.5, an average value for steel.

The thickness of the tire is nominally 3 in., but as the outside tread is turned to 80 in. diameter ($R_2 = 40$), the actual thickness is very slightly greater, since R_1 is slightly less than 37 in. after shrinkage by an amount depending upon the contraction of the wheel center.

Neglecting for the moment the contraction of the wheel center, the value of P_1, the stress on the inner fiber of the tire, becomes from Equation [2] 13.138 Q_1, and since from [1] $Q_1 = 12.242 - P_1$, the value of P_1 becomes 13.25 tons per sq. in.

The strain on the inside layer of the tire, or the stress (13.25 tons) divided by the modulus of elasticity (13.250), is .001, i.e., the actual or terminal shrinkage is 1 in 1000.

If the wheel center be supposed to have contracted 0.02 in. in the diameter, Equation [2] gives $P_1 = 13.094\ Q_1$, from which $P = 13.255$ tons per sq. in. The effect of the contraction on the stress in the tire may, for ordinary cast-steel wheel centers, be neglected.

The difference between the effective or real shrinkage allowance of the tire and nominal allowance is of interest. In the case cited by the writer this difference amounted to 0.0185 in., which may be taken as the actual contraction of the 74-in. wheel.

It may be of interest to investigate experimentally the question of the amounts of contraction of wheel centers for different diameters. While from the above figures it appears that the maximum stress on the inner fiber of the tire is 13.25 tons per sq. in., it is half the elastic limit of the steel. It may happen that an occasional tire is gaged too tightly, in which case the nominal shrinkage will be considerably higher. The above stress in the tire is static and it is probable that additional alternating dynamic loads may, in time, produce the results of repeated stresses and ultimately cause fracture of apparently sound tire which has been shrunk on under the maximum hoop tension considerably less than the ordinary elastic limit of the material, which would explain certain cases of fracture. (*The Engineer*, vol. 124, no. 3222, September 28, 1917, p. 263, 2 figs., *cp*)

Steam Engineering

INVESTIGATION OF STRESSES IN DIGESTER SHELLS, H. O. Keay, Mem.Am.Soc.M.E.

In the design of sulphite-digester shells it has long been the practice to calculate the stresses by means of conventional formulæ for cylindrical pressure vessels, without any apparent consideration whatever of the possible action of the masonry lining. Where such a lining reaches a thickness of 7 in. or more, however, there is present a circular arch of considerable strength. This investigation was undertaken with the view to demonstrating that under certain circumstances such linings impose a heavy tensile stress upon the shells of digesters.

To settle the question of influence of temperature of the lining upon shell stresses, Prof. A. P. Mills and the author of the present article were requested two years ago by the Laurentide Co., Ltd., of Grand' Mère, P. Q., Canada, and the International Paper Company, to conduct a joint investigation of the behavior of the shell of a digester under working conditions.

The paper gives a detailed account of the methods of investigation used in the present case and presents the data in the form of curves.

Had no extraneous stresses been encountered, calculation shows that the magnitude of the value of the circumferential stresses (upper curve, Fig. 17) would have been approximately double those of the longitudinal stress (lower curve); but actually such is not the case, nor do the curves return to the base line of zero stress even when the digester has been cooled down to room temperature. Further, the difference between the maximum and minimum of neither the circumferential- nor the longitudinal-stress curve is as great as the calculated values corresponding with the known maximum internal pressure.

This can be accounted for in only one way, namely, that subsequent to the lining of the digester, compression had accumulated in this lining, reacting as a residual tensile stress in the plate. The effect of internal pressure and the elastic extension of the steel shell tend to relieve the compression in the lining and its consequent reaction on the shell. So, at the point of maximum internal pressure the resultant stress is necessarily less than the sum of the residual stress and that which would have been produced by hydrostatic pressure alone.

The residual circumferential stress is shown to be about 5000 lb. per sq. in. of the solid plate, and the maximum circumferential stress in the final cook reaches a value of 13,000 lb. per sq. in. with a corresponding longitudinal stress of 10,400 lb. per sq. in. Since the strength of the longitudinal

seam expressed in terms of the strength of the gross section of the uncut plate is 85.42 per cent, and that of the girth seam 67.19 per cent, the corresponding maximum circumferential stress becomes $13{,}000/0.8542 = 15{,}220$ lb. per sq. in. and the maximum longitudinal stress $10{,}400/0.6719 = 15{,}480$ lb. per sq. in. The higher stresses encountered in making the first cook after the digester had been cooled down emphasize the necessity for extreme care in bringing the digester up to working temperature and pressure in similar circumstances.

A series of tests was also run on new digesters selected at the Laurentide Company's sulphite plant for the purpose of determining the strength of the longitudinal seams. These tests gave results fairly consistent with the results of the tests referred to above. The behavior of the digester shells was quite similar, although in the former instance the lining cement was gaged with the sodium silicate at 5 deg. B., while in the latter case the cement was gaged with a similar solution at approximately 36 deg. B., a circumstance which appears to indicate that if the silicate has an influence in producing permanent expansion of the lining, an excess over a certain amount has little or no effect. (*Paper,* vol. 21, no. 4, October 3, 1917, pp. 14, 16, 18, 20, 22, 24 and 26, 10 figs., *e*)

New Boilers for Ashley Street Station

Data of an additional boiler installation for driving the new 25,000-kva. turbines now being installed in the Ashley Street Station of the Union Electric Light and Power Company, St. Louis, Missouri, and to increase the general steam capacity by about 60,000 kw. to take care of the growing business of the plant.

To do this the 28 Scotch marine and small water-tube boilers located on the first floor of a double-deck boiler plant will be replaced by 24 of the new type of Edge Moor boilers.

The Scotch marine boilers with internally fired furnaces did not prove successful, owing to their being ill-suited to the burning of low-grade Western coals which must be used in the St. Louis district.

The new boilers are equipped with underfed stokers. The installation of such stokers in a power station which must rely on low-grade Illinois coal was a new and somewhat radical departure, but after six months of operation the success of the venture was proved beyond a doubt. Boiler ratings up to 200 per cent are being carried continuously with an over-all boiler and furnace efficiency of 70.5 per cent.

Precision "Three-in-One" air gages are used for indicating draft pressures in the blowers, furnaces, and uptakes. The average draft in the uptake is $1\frac{1}{4}$ in. of water, with that in the furnace slightly below atmospheric pressure, while the available force of the air blast is 4 in. With this equipment it is impossible to obtain ratings in excess of 300 per cent for periods of one hour or slightly longer. On the economizers are "Tycos" double-pen recording thermometers for incoming and outgoing water temperatures. Each boiler is also equipped with a General Electric indicating flow meter calibrated to read directly in hundreds of boiler hp.

Edge Moor boilers are used. They are built up with the side-wall construction shown in Fig. 18. These walls, which have the usual firebrick lining 9 in. thick opposite the furnace proper, are backed up with hollow building tile 8 in. thick bonded in with common red brick. On the outside of the tile is placed 2 in. of air-cell covering securely fastened and cemented in place, then covered with canvas. On the outside of the building tile and beneath the 2-in. covering is placed a coating of "boiler seal," the object of this being to stop up cracks and prevent air leakage through the setting. Six months' operation of the boilers has proved that these settings are entirely satisfactory. (*Power,* vol. 40, no. 15, October 9, 1917, pp. 480-484, 10 figs., *d*)

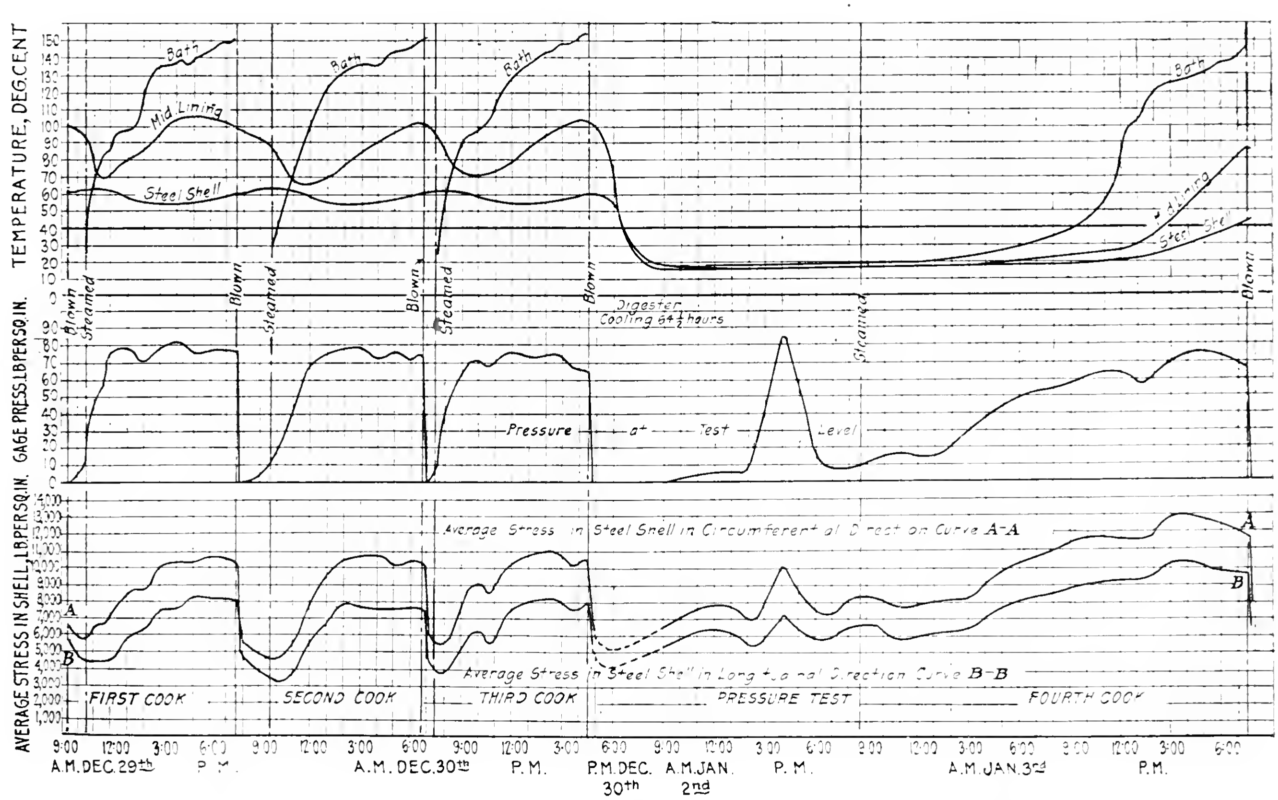

Fig 17 Data of Tests of a Digester Shell for Circumferential and Longitudinal Stresses

Female Labor's Place in the Automotive Industry, Allen Sinsheimer

Discussion of the probability of increase of female labor in industry, based on the experience of England. The author lays great emphasis on the fact that if female labor is employed, proper conditions should be provided, especially with respect to food

By comparing the increase in the number of women employed in gainful occupations in the United Kingdom with

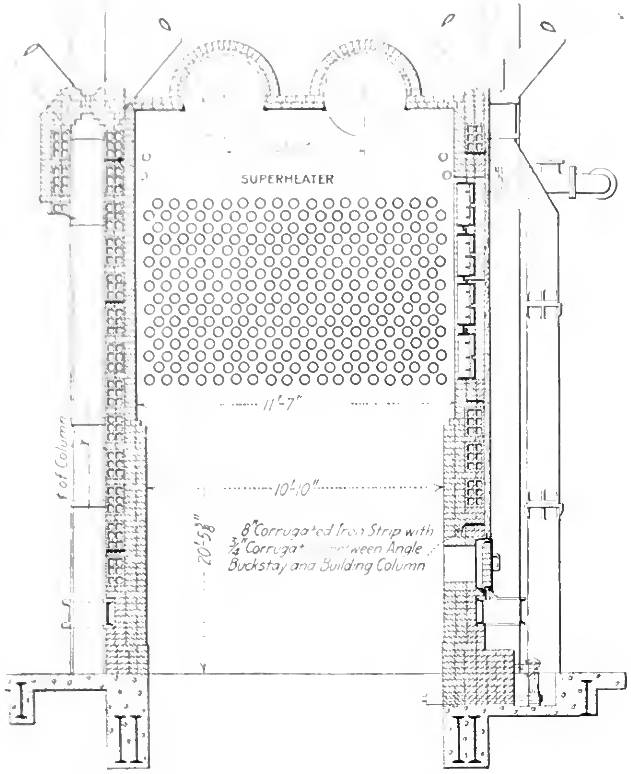

Fig. 18 Wall Construction of Boiler Setting

that now employed in America, the writer comes to the conclusion that one may expect an access of more than 2,000,000 into the industry. This condition will create many problems peculiar to female labor and involving such things as illiteracy and lack of knowledge of English; hours of labor; rates of wages and earnings; efficiency of female labor; labor conditions affecting health; housing and safety; industrial canteens; restrooms and matrons; state legislation affecting female labor; feminine temperament; employment of mothers; time keeping and labor turnover; physical capacity.

As regards the knowledge of English, the writer tells of the so-called Sicher plan, which includes a school incorporated with daily work where three-quarters of a hour of daily instruction is given without interruption in factory work. The schoolroom is set aside in a quiet out-of-the-way corner of the factory. The school has the coöperation of the Board of Education. The total cost of 35 weeks' instruction per girl is $16.80 for the firm and $14.80 for the city. It was found that for 32 weeks preceding the opening of the school the wages of the girls who later became pupils averaged 19.5 cents per hour, while that which the literate girls received was 23.2 per hour.

As regards the hours of labor, experiments in this country with female labor confirmed the experience in England, namely, that short hour shifts are preferable to long-hour shifts. The Miller Rubber Company, of Akron, Ohio, experimenting by reducing the hours of labor from ten to eight, discovered that female labor earnings of 16.4 cents per hour increased to 21.5 per hour in six months, that production increased from 82 per cent to 107 per cent and attendance by 10 per cent in the same period.

As regards efficiency, inquiry among manufacturers in this country shows that female labor applied to certain light machine work and to work where deftness of hand is required is more productive than male labor. The Link-Belt Company of Indianapolis finds women more efficient and productive than men when assembling small links into chains and handling packing for heat-treating purposes. The same experience is reported by several other large concerns, among them the International Harvester Company and the Westinghouse Electric Company.

On the other hand, some manufacturers find that women at machine work require more supervision than men, because when a machine breaks down they are unable to repair it, or because the women are unable to handle the large and heavy output resulting from their productive effort.

Conditions of labor affecting health are of particular importance where female workers are employed. Sanitary washrooms and cloakrooms are essential. Chairs should be provided wherever possible. Provision for meals should allow three-quarters of an hour to one hour, and the interval between meals should not exceed four hours. The housing problem also becomes very important.

The temperament of female labor affects production. Women are less inclined to become labor machines than men. Female supervisors are more efficient than men when handling female labor, because of their ability to gain the workers' confidence, to learn their grievances, to determine home troubles, or discover any factors which prevent them from attaining a normal productive output. On the other hand, the general impression is that women are less inclined to change their positions than men.

The physical capacity of women differs from that of men and they are particularly liable to injury through lifting weights or by long standing. Chief among the slight ailments to which the employers will do well to direct their attention are disturbances of digestion due to unsuitable food, irregular and hurried meals, fatigue, anemia, headache, nervous exhaustion, muscular pain, and weakness and derangement of special physiological functions. English manufacturers have found it profitable to employ women doctors to examine applicants for work. It was found that prolonged standing may be the cause of permanent and serious injury to women, and where standing is unavoidable they make the hours and spells of employment short and provide seats for frequent intervals of rest.

Experiments in the motor plants of the United States show that as test drivers women are more careful than men and that they drive more responsibly through city streets. A number of concerns have found that on assembling, inspection and light machine work women may be employed with excellent results. The Dayton Engineering Company, employing several hundred women workers, has installed a factory school for the girls where they are taught light machine work, receiving the guaranteed day rate while studying.

The writer proceeds to quote the views of Samuel Gompers, President of the American Federation of Labor, on female labor. An interesting part of this is the quotation from the

report of an inquiry carried out by the Federation of Metal Workers of Germany in war times.

From this report it appears that women are often engaged in work which is entirely too strenuous for them and sometimes suffer from the consequences. Thus, the women complain very much of abdominal pains caused by frequently having to lift, without any tackle, sheets weighing 52 lb. In the foundry they have, for instance, to push the casting pans about, work that overtaxes their strength. One woman sustained a rupture of the groin through performing this work. At steam hammers women have to draw bomb castings (weighing about 88 lb.) in a state of incandescence from the furnace to the hammer. It appears that a continuous effort is made in Germany to employ women at the hardest and most dangerous jobs: at steam hammers, shaping machines, core making, pneumatic lifts, transporting heavy cores, casting with pans and with hand ladles. One result of the hard work in one establishment is that out of 42 women nearly one-third have been disabled by disease.

Of the women employed in the metal trades 79 per cent work from 11 to 13 hours per day, with much overtime and Sunday work.

As regards wages, the treatment does not appear to be fair. Thus, in one establishment it is the custom that piece-work wages must not exceed the average time wages by more than 75 per cent. Should a woman through diligence and skill earn a larger sum, the piece-work rate was reduced in her case. The inquiries showed that only 9 per cent of the women were paid at rates corresponding to those paid to men for identical work. (*The Automobile and Automotive Industries,* Nos. 13 and 14, September 27 and October 4, 1917, pp. 525-531 and 592-593, illustrated.)

The Growth of Mining and Metal Industries in France

BEFORE the war, France was already considered by experts as the richest country of the world in iron ore, after the United States. Besides the basins of Lorraine, which produce three billion tons of ore, she possesses the basin of Normandy, which, in an area of 40,000 square kilometers, contains, according to a recent estimate, nearly a billion tons of a superior quality of ore yielding 50 per cent of iron. In 1914, 21 grants in mining districts, producing 1,152,000 tons a year, already existed in the departments of the Orne, Manche and Calvados, which yielded 648,000 tons with six grants only under exploitation. About the middle of 1916, a large society, entirely French, the Société Normande de Métallurgie, was founded, with a capital of 40 million francs, by Messrs. Schneider and Co., the great Creusot manufacturers, the Société des Aciéries de la Marine et Homécourt, and several shareholders belonging to the metallurgic world. This new society leased the foundries and fittings previously organized, or provided for, by the Société des Hauts-Fourneaux de Caen, formed in 1892, and in July 1916 started the works afresh. They are situated at Mondeville-Colombelle near Caen, and stand over 400 hectares (about 2½ acres), 200 of which are on the plateau and 200 in the valley of the Orne. About thirty kilometers distant is the Soumont mine, capable of yielding even now 4000 tons of iron ore a month, and which, in the near future, will have a far larger output.

The establishments of the Société Normande de Métallurgie comprise gas and coke furnaces, large steel works, a flattening mill, smelting works and blast furnaces. Three stations, and a railway line 33 km. long, facilitate the transport service. The line was made by a branch society and runs between the above foundries and the Soumont mines. At present there are 4 batteries of 42 furnaces each, producing 1000 tons of coke a day. In January 1918 two other batteries, now under construction, will be in working order and will bring the output up to 1500 tons a day, or 500,000 tons a year. The coke, collected by an ingenious system of inclined planes and chains, after being sorted out, is sent in trucks to Government metal works. Gas undergoes a series of processes for the purpose of extracting the secondary products obtained by the distillation of coal such as tar, phenol, benzine, toluol, naphthalin, sulphate of ammonia, used in the manufacture of explosives and for dyeing purposes, and which, prior to the war, were almost exclusively produced by Germany.

The blast furnaces, the first of which has been recently inaugurated, are in themselves 29 meters high, but with their basements tower 45 meters above the foundry ground plot. They can produce 400 tons a day, which is the largest output obtained in Europe up till the present day. To each is affixed a battery of 5 metal cylinders, or "Cowpers," 7 meters in diameter, for heating the air for the combustion of coke, and the reaction of carbon on the oxides of the ore, which is the source of production for cast iron. Three of these gigantic blast furnaces will be ready in the autumn of 1918, and the whole installation, when completed, will allow of an output of 450,000 tons of cast iron a year. The steel works, properly so-called, contain 4 converters of 30 tons, and 5 Martin furnaces of 30 tons, allowing of an output of 275,000 tons of Thomas steel and 125,000 tons of Martin steel every year. The flattening mill can pass 500,000 tons of ingots a year, and is supplied with several reversible trains for the production of all small samples. The Société already possesses stocks of iron ore sufficient to insure the supplies for its factories without any difficulty. It has had a large water tower, 66 meters in height, built in the neighborhood, with two reservoirs and a canal to the Orne, so that 10,000 cubic meters of water could be supplied hourly. A vast hall 200 meters long contains the electric machinery for distributing motive force, two turbo alternating generators of 3000 kilowatts, one of 5000, six gas alternating generators of 6000 hp., and three of 3000 hp. A private harbor has been built on the Orne canal, and it is now ready for vessels of 2000 tons, and will soon be open to boats of 8000 tons' burden.

The preceding facts show how the Société Normande has been able to create in the midst of war one of the most important metallurgic centers in the whole of France. The mining industry of the entire region has followed its example. At present 30 fresh grants have been made for exploiting of the layers of iron in Normandy, Brittany and Anjou. On the other hand, the French Government is preparing to work the Littry coal fields, situated between Saint-Lô and Bayeux. Lastly, owing to many recent improvements, trade with Caen harbor is increasing every day. From 890,000 tons in 1910, it rose to 1,126,000 in 1913.—Paris Chamber of Commerce Bulletin, September 1917.

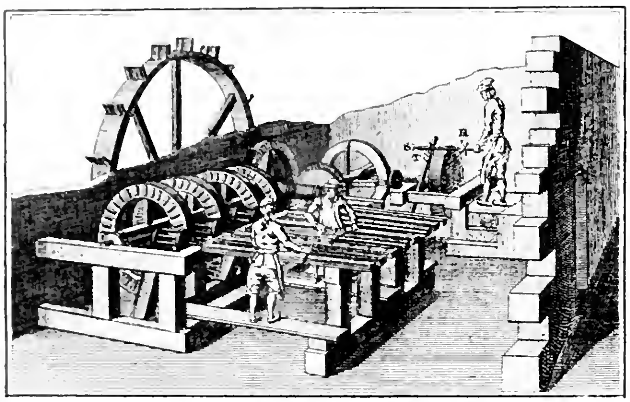
LIBRARY NOTES

From the Libraries of the Four Founder Societies and the United Engineering Society, in the Engineering Societies Building, New York City

Diderot's Encyclopedia

THE United Engineering Society Library has been fortunate in securing a well preserved copy of the famous French "Encyclopedie" edited by Denis Diderot (Encyclopédie, ou Dictionnaire Raisonné des Sciences, des Arts et des Métiers, par une société de gens de Lettres. Mis en Ordre & publié par M. Diderot; & quant a la Partie Mathématique, par M. d'Alembert . . . 3rd éd. Geneve, Pellet, 1777-1779. 36v., fronts. ports. tables. With 3v. of copper plates.) The Encyclopedia Britannica characterizes this work as one of "greatest and most remarkable enterprises of the 18th century." The germ of the "Dictionnaire" originated in a plan to translate from English into French, Ephraim Chambers' "Cyclopædia," or an Universal Dictionary of Art and Sciences, containing an Explication of the Terms and an Account of the Things Signified thereby in the Several Arts,



How They Made Munitions in Diderot's Time

The old encyclopedia contains many such illustrations of interest

and the several Sciences, Human and Divine." (London, 1728. 2v.)

After much quarreling between the publisher and those who had undertaken the translation, it was abandoned. An original French work was then planned and Diderot engaged as editor. "Instead of a mere reproduction of Chambers, he persuaded the bookseller to enter upon a new work, which should collect under one roof all the active writers, all the new ideas, all the new knowledge, that were then moving the cultivated class to its depths."

No other encyclopedia, it is safe to say, ever had so stormy, so romantic, and eventful a career. The work was by no means a piece of closet scholarship. Into it was poured the spirit of the democratic and scientific movement just preceding the French Revolution. The encyclopedia burns with the desire of the men of that time to conquer nature. It is aflame with the passion for experiment and exploration. Needless to say, it met with the violent opposition of the powerful ecclesiastics and the despotic French court, who instinctively felt this work to be a menace to blind faith in the traditional explanations of natural phenomena and a challenge of the unthinking worship of autocratic authority. Rousseau wrote the articles on music. Montesquieu, Turgot, and Voltaire were among the more than twenty contributors. Such a galaxy of free spirits did not inspire the trust of the then tottering French feudalism. In 1749 Diderot was imprisoned at Vincennes in close confinement for twenty-eight days, and cooped up in the castle an additional three months and ten days. The first two volumes of the encyclopedia were suppressed "as being dangerous to the king's authority and religion." The plates were ordered seized but could not be found. After work had been resumed, the Parliament of Paris, in 1759, stopped the sale of the Encyclopédie and ordered all copies to be burned. In 1766 Lebreton, the publisher, was forced to show his subscription list and was put in the Bastille for eight days. The famous beauty, Madame de Pompadour, who had befriended the undertaking from the first, pleaded for the lifting of the ban upon it, saying to the king that she could "know no longer how her rouge and silk stockings were made. The duc de la Vallière regretted that the king had confiscated their encyclopedias, which could decide everything. The king said he had been told that the work was dangerous, but as he wished to judge for himself, he sent for a copy. Three servants with difficulty brought in the 21 volumes. The company found everything they looked for, and the king allowed the confiscated copies to be returned." Lebreton, the publisher, set up the copy exactly as it came from the editor, but after final revision secretly removed all parts he felt too bold. It was thus that this great scientific work fared.

Diderot was the contributor of articles on philosophy, the arts and trades. "He passed whole days in workshops, and began by examining a machine carefully, then he had it taken apart and put together again, then he watched it at work, and lastly worked it himself. He thus learned to use such complicated machines as the 'stocking- and cut-velvet looms." The copper plates of this set are most excellent. They are valuable as records of the early history of the machinery from which the factory system of today has been developed. The whole work illumines the dawn of the modern world, the age of engineering.

Engineers of today are so busy making history, that they have little time to write it. But there are those who take a deep interest in tracing the development of their various professions. The United Engineering Society Library exists primarily as a working tool for the man in active practice. However, through the generosity of its friends, its has received some rare collections of books, such as the Wheeler and Raymond gifts, and is yearly becoming stronger in source material on engineering history. The "Encyclopédie" of Diderot is regarded as a noteworthy addition.

F. V. A.

For all fuller account see the Encyclopædia Britannica under "Encyclopædia" and "Diderot, Denis," from which articles the above account was compiled.

The addition to the Engineering Societies Building is now completed and the Library restored to its normal condition.

U. E. S. Accessions

Abstracts of Current Decisions on Mines and Mining Reported from January April, 1917. (U. S. Bureau of Mines. Bulletin 152). *Washington, 1917.* Purchase.

Advanced First-Aid Instructions for Miners. A Report on Standardization. (U. S. Bureau of Mines). *Washington, 1917.* Purchase.

American Institute of Metals. Transactions. vol. X. *Buffalo, 1917.* Purchase.

American Society for Testing Materials. Membership List. Charter and By-Laws, 1917. *Philadelphia, 1917.* Purchase.

American Society of Agricultural Engineers. Transactions, vol. 10, nos. 1-2. *Ames, 1917.* Gift of American Society of Agricultural Engineers.

The Application of Efficiency Principles. By George H. Shepard The Engineering Magazine Co. *New York, 1917.* Cloth, 6 x 9 in., 368 pp., 7 figs. $3. Gift of the publisher.

Bangor (Me.) Mayor's Address. The Annual Reports of the Several Departments and the Receipts and Expenditures for 1916-17. Gift of City Clerk, Bangor, Me.

Bibliography of Fishes. Vol II, Author's Titles L-Z. American Museum of Natural History. *New York, 1917.* Purchase.

Business Law for Engineers. By C. Frank Allen. Part I. Elements of Law for Engineers; Part II. Contract Letting. McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth. 6 x 9 in., 431 pp. $3. Gift of the publisher.

Business Statistics. Edited by Melvin T. Copeland. Harvard University Press. *Cambridge, 1917.* Cloth, 6 x 9 in., 696 pp., 3 figs. $3.75. Gift of the Publisher.

Chemical Abstracts, Decennial Index, 1907-1916. Authors, A-K. *Easton, 1917.* Purchase.

Coal Mine Fatalities in the United States, 1916. *Washington, 1917.* Purchase.

Coal Resources of District II, Jackson, County, Ill. (Illinois State Geological Survey. Cooperative Coal Mining Series. Bulletin 16). *Urbana, 1917.* Purchase.

Coking of Illinois Coals. (U. S. Bureau of Mines. Bulletin 138). *Washington, 1917.* Purchase.

The Composition of Technical Papers. By Homer Andrew Watt. McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth, 5 x 8 in., 431 pp., 41 figs. $1.50. Gift of the Publisher.

Congressional Directory. 65th Congress, 1st Session, April 1917. *Washington, 1917.* Gift of Peter J. Dooling.

Deming, New Mexico. (U. S. Geological Survey. Folio No. 207). *Washington, 1917.* Purchase.

Detroit Folio. Wayne, Detroit, Grosse Pointe, Romulus, and Wyandotte Quadrangles, Michigan. (U. S. Geological Survey. Folio No. 205). *Washington, 1917.* Purchase.

Eastman Kodak Company. Abridged Scientific Publications from the Research Laboratory. Vol. II, 1915-16. *Rochester, 1917.* Gift of Eastman Kodak Company.

Electrical Machinery; Principles, Operation and Management. By Terrell Croft. McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth. 6 x 8 in., 318 pp., 302 figs. $2. Gift of the publisher.

Electrical Measurements. By Frank A. Laws. McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth, 6 x 8 in., 719 pp., 442 figs. $5. Gift of the publisher.

The Electron; Its Isolation and Measurement and the Determination of Some of Its Properties. By Robert Andrew Millikan. The University of Chicago Press, *Chicago* (Copyright *1917*). Cloth, 5 x 8 in., 261 pp., 33 figs. $1.50. Gift of the publisher.

The Elements of Hydrology. By Adolph F. Meyer. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 6 x 9 in., 487 pp., 287 figs., 2 diagrams, 3 maps. $4. Gift of the publisher.

Engineering for Masonry Dams. By William Pitcher Creager John Wiley & Sons, Inc., *New York, 1917.* Cloth. 6 x 9 in., 237 pp., 98 figs. $2.50. Gift of the publisher.

Examination of Water; Chemical and Bacteriological. By William P. Mason. 5th ed. rev. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 5 x 8 in., 186 pp., 16 figs. $1.25. Gift of the publisher.

Extraction of Gasoline from Natural Gas by Absorption Methods. (U. S. Bureau of Mines. Bulletin No. 120). *Washington, 1917.* Purchase.

Federal Valuation of the Railroads in the United States. Statement prepared by H. C. Phillips, General Secretary of the developments in connection with federal valuation as of Sept. 20, 1917. Gift of Clemens Herschel.

Fishes of the West Coast of Peru and the Titicaca Basin. (U. S. National Museum. Bulletin 95). *Washington, 1917.* Purchase.

Flotation of Ores (Bibliography of Recent Literature), July-Dec., 1916. (U. S. Bureau of Mines. Technical Paper 176). *Washington, 1917.* Purchase.

The Flying Book, 1917. Edited by W. L. Wade. Longmans, Green & Co., *New York, 1917.* Boards, 6 x 9 in., 291 pp., 171 figs. $1.25. Gift of the publisher.

Georgia & Florida Railway. Annual Report. 7th-9th. *Augusta, Ga., 1914-1916.* Gift of Georgia & Florida Railway.

Hammond's Standard Atlas of the World. Ed. 4. *New York, 1917.* Purchase.

Handbook of Clearing and Grubbing; Methods and Cost. By Halbert Powers Gillette. Clark Book Co., Inc., *New York, 1917.* Cloth, 5 x 7 in., 240 pp., 67 figs. $2.50. Gift of the publisher.

Historia del Ferrocarril de la Sabana por el Socio de numero senor doctor don Alfredo Ortega. July 19, 1917. *Bogota, 1917* Gift of Sociedad Colombiana de Ingenieros.

History of Transportation in the United States before 1860. Prepared under the direction of Balthasar Henry Meyer by Caroline E. MacGill and a staff of collaborators. Carnegie Institution. *Washington, 1917.* Paper, 7x10 in., 678 pp., 6 maps. $6.50. Gift of the publisher.

Institution of Mechanical Engineers. Proceedings. January-May 1917. *London, 1917.* Purchase.

The Iron Ores of Lake Superior; Containing Some Facts of Interest Relating to Mining and Shipping of the Ore and Location of Principal Mines. By Crowell & Murray. 3d ed. with original maps of the ranges. The Penton Press Co., *Cleveland, 1917.* Cloth. 6 x 9 in., 316 pp., 7 figs., 13 maps. Gift of the authors.

Is Civilization a Disease? By Stanton Coit. Houghton Mifflin Co., *Boston and New York, 1917.* Cloth, 5 x 7 in., 136 pp. Gift of the University of California Press.

Leavenworth-Smithville Folio, Missouri-Kansas. (U. S. Geological Survey. Folio No. 206). *Washington, 1917.* Purchase.

McGraw Electric Railway List, August 1917. *New York, 1917.* Purchase.

Mining of Thin Coal Seams as Applied to the Eastern Coal-Fields of Canada. (Canada. Mines Department. No. 432). *Ottawa, 1917.* Purchase.

Modern Machine Shop; Construction, Equipment and Management. A Comprehensive and Practical Treatise on the Economical Building, the Efficient Equipment and Successful Management of the Modern Machine Shop and Manufacturing Establishment. By Oscar E. Perrigo. 2d ed., revised and enlarged. The Norman W. Henley Publishing Co., *New York, 1917.* Cloth, 6 x 9 in., 384 pp., 219 figs. $5. Gift of the publisher.

Official Automobile Blue Book, 1917; Standard Road Guide of America. Volume A, New York City and the Metropolitan District Embracing a Radius of 100 Miles from Columbus Circle. The Automobile Blue Book Publishing Co., *New York, Chicago, San Francisco* (copyright, *1917*). Leather, 5 x 9 in., 624 pp., illustrated, 1 map. $3. Gift of the publisher.

New York City. Department of Water Supply, Gas and Electricity. Annual Report 1908, 1915-1916. Gift of Department.

Ohio State University. Report of the Board of Trustees. 46th, 1916. *Columbus, 1916.* Gift of Ohio State University.

Opérations Minières dans la Province de Québec, rapport sur les l'année 1916. *Québec, 1917.* Purchase.

Organisation Physiologique du Travail. Par Jules Amar. Préface de Henry Le Chatelier. H. Dunod et E. Pinat, *Paris, 1917.* Paper, 7 x 10 in., 374 pp., 134 figs. 18 francs. Gift of the publisher.

Organization, Purpose and Methods of Underwriters' Laboratories. *Chicago, 1917.* Gift of J. I. Banash.

Parallel Tables of Slopes and Rises; In Combination with Diagrams of Slopes and Rises and Other Tables for Bridge and Structural Engineers, Draftsmen, Checkers, Templet Makers, Builders, and Vocational Schools. By Constantine K. Smoley. McGraw-Hill Book Co., Inc., *New York, 1917.* Leather, 5 x 7 in., 330 pp., 41 figs. $4. Gift of the publisher.

Plattsburg Training Camp, New York. Topographical map. *1917.* Purchase.

Practical Wireless Telegraphy; A Complete Text-Book for Students of Radio Communication. By Elmer E. Bucher. Wireless Press, Inc., *New York* (copyright *1917*). Cloth, 6 x 9 in., 322 pp., 323 figs. $1.50. Gift of the publisher.

The Principles of Iron Founding. By Richard Moldenke. McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth, 6 x 9 in., 517 pp., 45 figs. $4. Gift of the publisher.

Production of Explosives in the United States during the Calendar Year 1916. (U. S. Bureau of Mines. Technical Paper 175). *Washington, 1917.* Purchase.

Publishers' Trade List Annual, 1917. *New York, 1917.* Purchase.

Railroad Construction; Theory and Practice. A Text-Book for the Use of Students in Colleges and Technical Schools, and a Hand-Book for the Use of Engineers in Field and Office. By Walter Loring Webb. 6th ed. rev. and enl. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 4 x 7 in., 831 pp., 218 figs. $4. Gift of the publisher.

Researches of the Department of Terrestrial Magnetism, Volume III. Ocean Magnetic Observations 1905-1916; and Reports on Special Researches. By L. A. Bauer with the collaboration of W. J. Peters, J. A. Fleming, J. P. Ault, and W. F. G. Swann. Carnegie Institution of Washington, *Washington, 1917.* Paper, 9 x 11 in., 447 pp. $10. Gift of Carnegie Institution.

Results of Magnetic Observations Made by the United States Coast and Geodetic Survey in 1916. (U. S. Coast and Geodetic Survey. Special publication No. 42). *Washington, 1917.* Purchase.

Shape Book; Containing Profiles, Tables and Data Appertaining to the Shapes, Plates, Bars, Rails and Track Accessories Manufactured by the Carnegie Steel Company. The Carnegie Steel Co., *Pittsburgh* (copyright *1917*). Leather, 5 x 8 in., 352 pp., 270 figs. $1. Gift of the Carnegie Steel Co.

Standard Table of Electrochemical Equivalents and Their Derivatives, with Explanatory Text on Electrochemical Calculations, Solutions of Typical Practical Examples and Introductory Notes on Electrochemistry. By Carl Hering and Frederick H. Getman. D. Van Nostrand Co., *New York, 1917.* Leather, 4 x 7 in., 130 pp., 8 figs. $2. Gift of the publisher.

Société Technique de l'Industrie du Gaz en France. Compte-Rendu du Trente-Neuvième Congress, June 1912. *Paris, 1912.*

PERSONALS

IN these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by November 10 in order to appear in the December issue.

CHANGES OF POSITION

B. DENVER COPPAGE has resigned as chief engineer of The Pusey and Jones Company, Wilmington, Del., and is now experimental engineer on the staff of E. I. du Pont de Nemours and Company, of the same city.

CHENOWETH HOUSUM has left the employ of the Allis-Chalmers Manufacturing Company, Milwaukee, Wis., to enter the Government service on certain special development work.

JOAQUIN R. MASFERRER has resigned his position with the South Porto Rico Sugar Company, as assistant steam engineer of their electric plant at the Guanica Centrale, and has accepted the position of assistant mechanical engineer with the Haytian American Sugar Corporation, of Port-au-Prince, Hayti.

RAYMOND T. BELL, formerly engineer of tools and methods, Wahl Adding Machine Company, Chicago, Ill., has become identified with the Teetor Adding Machine Company, Des Moines, Iowa.

HAROLD A. RICHMOND, president of the American Emery Wheel Works, Providence, R. I., has become associated with the General Abrasive Company, Inc., Niagara Falls, N. Y.

PAUL D. HAWKINS has become affiliated with Lybrand Ross Brothers and Montgomery, New York. He was, until recently, connected with the Newton Gas and Electric Company, Newton, N. J.

JULIUS G. BERGER, industrial power engineer, Public Service Corporation, Trenton, N. J., has assumed the duties of chief engineer of the William Gordon Corporation, Philadelphia, Pa.

JACOB GINSBURG, formerly associated with the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., has accepted the position of mechanical engineer with the Lehigh Portland Cement Company, Iola, Kan.

CLAYTON A. HOOVER, formerly accountant and auditor with the Southwark Foundry and Machine Company, Philadelphia, Pa., has entered the employ of the Vim Motor Truck Company, of the same city, in the capacity of treasurer.

DANIEL T. MACLEOD, president of the Hamilton By-Products Company, New York, has assumed the position of vice-president of the Elkhorn Piney Coal Mining Company, Milwaukee, Wis.

ARTHUR F. CARY has accepted the position of mechanical engineer with the Stanley Motor Carriage Company, Newton, Mass. He was, until recently, superintendent of trade school of the Massachusetts Reformatory, Watertown, Mass.

BENJAMIN G. DENLINGER, formerly mechanical foreman of the Astoria Light, Heat and Power Company, Long Island City, N. Y., has entered the service of the Keller Mechanical Engraving Company, Brooklyn, N. Y.

FREDERICK R. SHANLEY, efficiency engineer with L. V. Estes, Inc., Chicago, Ill., has become identified with the Northwestern Knitting Company, Minneapolis, Minn.

FREDERICK J. BRENGEL, assistant superintendent, manufacturing department of the Safety Car Heating and Lighting Company, Jersey City, N. J., has assumed the position of superintendent of the Bailey Meter Company, Boston, Mass.

A. F. VAN DEINSE, until recently associated with the Springfield Gas and Electric Company, Springfield, Mo., in the capacity of general manager, has become affiliated with the Federal Light and Traction Company, New York.

HERBERT L. WHITTEMORE has resigned from the associate professorship of mechanics at the University of Oklahoma, Norman, Okla., and accepted a position with the Bureau of Standards, Washington, D. C.

P. J. BELL has resigned his position as manager of the San Carlos Milling Company, Ltd., effective July 1, and has accepted a position with Welch, Fairchild and Company, Inc., of Manila, P. I.

JOHN R. DUPRIEST, formerly head of the mechanical engineering department of the University of Idaho, Moscow, Idaho, has become professor of steam and gas engine design at Rensselaer Polytechnic Institute, Troy, N. Y.

CHARLES G. ROBINSON, formerly engineer with the Wheeling Steel Casting Company, Wheeling, W. Va., has assumed the duties of president of The Ohio Mold and Foundry Company, Cincinnati, Ohio.

IRA DYE, until recently erecting engineer with Henry R. Worthington, Harrison, N. J., has been appointed night superintendent of the Weir Frog Company's plant at East Norwood, Ohio.

J. E. GIBSON has accepted the position of manager of the water department under the Commissioners of Public Works, Charleston, S. C. He was formerly connected with the American Pipe and Construction Company, Philadelphia, Pa., in the capacity of principal assistant engineer.

DONALD B. PRENTICE, instructor of mechanical engineering, Sheffield Scientific School, Yale University, New Haven, Conn., has accepted the position of assistant professor of mechanical engineering at Lafayette College, Easton, Pa.

CHARLES A. HAYNES has resigned his position as superintendent of Unger Brothers, of Newark, N. J., to accept a similar position with the Mohegan Tube Works, Brooklyn, N. Y.

WILLIAM N. STEVENS, formerly identified with the Cincinnati Milling Company, has entered the service of the Gisholt Machine Company, Madison, Wis.

ARTHUR H. AAGAARD, formerly instructor of steam and gas engineering, College of Mechanics and Engineering, University of Wisconsin, Madison, Wis., has accepted a position at Rice Institute, Houston, Tex.

ROBERT M. MATTHEW, until recently connected with the Ohio Tool Company, Charleston, W. Va., in the capacity of machine-shop foreman, has assumed the position of assistant superintendent of the Whitaker Manufacturing Company, of Chicago, Ill.

CHARLES MAAK, until recently in the employ of the Metals Production Equipment Company, Springfield, Mass., as assistant chief engineer, has become affiliated with the Quigley Furnace Specialties Company, New York.

AUBREY I. BROWN has accepted the position of assistant professor of mechanical engineering, Pennsylvania State College, State College, Pa. He was formerly on the faculty of Ohio State University, Columbus, Ohio, as instructor of mechanical engineering.

MARK A. E[illegible], formerly head of the [illegible] inspection with the Bosch Magneto Company, Plainfield, N. J., is now connected with the United States Signal Corps, as inspector of [illegible] planes and aeroplane engines.

HENRY L. U[illegible], engineer of the [illegible] Consolidated Gas Company of New York, has [illegible] with the B[illegible] Hayward Company, [illegible], Md.

FRANK J. BA[illegible], formerly sales engineer with Manning, Maxwell and Moore, New York, has [illegible] assistant works manager of the Putnam Machine Company, Fitchburg, Mass.

A. C. TOWNSEND, who has been connected with the Green Fuel Economizer Company in various capacities for the past twelve years, has resigned his position as assistant to general manager and is now associated with H. R. G[illegible], sales agent for power-plant equipment and the Moore Steam Turbine Corporation.

FRANK A. BROWNE, formerly manager of the Iroquois Works of the Barber Asphalt Paving Company, Buffalo, N. Y., is now connected

with the [illegible] Shipping Board, Washington, D. C., in the capacity of general purchasing officer.

[illegible] I. Pettersen, formerly connected with De Camp and Sloan Manufacturing Company, Newark, N. J., has accepted a position in the engineering department of the Hopkins and Allen Arms Company, Norwich, Conn.

Earl L. Consoliver, formerly in the employ of the American Auto [illegible] College, Omaha, Neb., has accepted the position of instructor in mechanical drawing and machine design in the Extension Division of the University of Wisconsin, Madison, Wis.

Clifford P. Staudinger, formerly assistant designer for the A. S. Heinrich Corporation, has taken a position in the experimental department of the Curtiss Engineering Corporation.

Arthur S. Lewis has resigned his position as travelling mechanical engineer and eastern representative with the Chicago-Cleveland Car Roofing Company, New York, to join the sales force of Flint and Chester, Inc., New York. As assistant to the president, Mr. Lewis will have charge of sales to railroads and other large corporations.

Clyde H. McClintock has severed his connections with the Denver Tramway Company, Denver, Colo., and is now associated with the Trinidad Electric Transportation Railway and Gas Company, Trinidad, Col., as construction engineer.

R. F. Peters, until recently senior mechanical engineer, valuation division of the Interstate Commerce Commission, Kansas City, Mo., has become identified with the St. Louis-San Francisco Railway Company, Springfield, Mo., as mechanical engineer.

ANNOUNCEMENTS

Major Francis B. Longley has been detailed as engineer officer in charge of the engineering department of the Signal Corps Aviation School, San Diego, Cal.

Porter H. Adams, recently chief engineer of the Basle-Adams Engineering Company, Boston, Mass., is now in the naval service of the United States, stationed at Rockland, Me.

Robert P. Lay, formerly assistant inspection engineer with the Curtiss Aeroplane and Motor Corporation, Buffalo, N. Y., is now assistant engineer in the motor experimental division of the same company, located at the Churchill Street plant, Buffalo, in charge of the design of all new motors developed by the company.

James Brakes, Jr., has accepted a position as testing engineer for the Kimberly-Clark Company, Neenah, Wis.

C. W. E. Clarke has gone to France on Governmental work in connection with the war.

R. Sanford Riley, president of the Riley Stoker Company, Ltd., has been elected president of the Murphy Iron Works, and in order to take care of the increased volume of business in the Riley underfeed stokers, additional manufacturing facilities have been arranged at the Detroit plant of the latter company. There will be no change in its management or policy.

Samuel S. Williams has enlisted in the Signal Service of the United States Army and is stationed at Atlanta, Ga.

James Allentuch announces that his name has been legally changed to James Allen-Tuch.

Commander H. I. Cone, U. S. N., marine superintendent, Panama Canal, has been detached from the Panama service and is now stationed at Washington, D. C., in the Navy Department.

Harry T. Anderson has become identified with the Dusenberg Motors Corporation, Elizabeth, N. J.

Major W. B. Gregory, of New Orleans, La., Engineers Officers' Reserve Corps, is now with the American Expeditionary Forces in France, reporting direct to General Pershing.

Lee L. Walker has been commissioned First Lieutenant, Ordnance Officers' Reserve Corps, and has been assigned to active duty in the carriage division.

Victor Schleyer has become affiliated with the Lea Courtenay Company, Newark, N. J., in the capacity of chief engineer.

Melbert W. Taber has been transferred from the position of Detroit district manager of the Asbestos Protected Metal Company, to that of factory manager of the company's plant at Ambridge, Pa.

Francis M. Bond was commissioned a Captain in the Ordnance Officers' Reserve Corps on June 26, 1917, spending about two months at the Frankford Arsenal and about one month at the Rock Island Arsenal training for inspection of ordnance materials. At present, Captain Bond is detailed to the plant of the Wagner Electric Manufacturing Company, of St. Louis, Mo., as inspector of ordnance in charge of the inspection and acceptance of materials on contract for the War Department.

Thomas J. Love, assistant mechanical engineer with the Dodge Sales and Engineering Company, New York, has become resident representative of the same company, at Indianapolis, Ind.

G. G. Schmidt announces the opening of the fifth annual season of The New York School of Heating and Ventilating, World Building, New York, of which he is secretary.

Paul M. Chamberlain has received a commission as Major, Ordnance Section, Officers' Reserve Corps.

D. P. Gaillard has been commissioned as First Lieutenant, Ordnance Officers' Reserve Corps, and is at present assigned to Division T (Nitrate Division), office of the Chief of Ordnance, Washington, D. C.

Lyman H. Miller, assistant superintendent of the American Steel and Wire Company, New Haven, Conn., has recently been elected president of the New Haven Safety Local Council of the National Safety Council, for the year 1917-1918.

Dean E. Foster, associate professor of mechanical engineering, University of Missouri, Columbia, Mo., is at present on leave of absence and is employed by Cosden and Company, refiners, as mechanical engineer on the design and construction of their Tulsa, Okla., 44-million-dollar refinery.

Albert H. Gfröhrer has been commissioned as First Lieutenant, Officers' Reserve Corps, Ordnance Division, War Department, Washington, D. C.

John M. Toppin has resigned his position of general manager with the Rhodes Manufacturing Company, Hartford, Conn.

Major-General George W. Goethals has been elected president of the Wright-Martin Aircraft Corporation, whose main plant is located at New Brunswick, N. J.

Philip F. Miller has entered upon duty as First Lieutenant, U.S.R., in the Field Artillery Section of the Carriage Division of the Ordnance Department, Washington, D. C.

W. Dean Burton has resigned as mechanical engineer with the McKeen Motor Car Company, Omaha, Neb., to become associated with the U. S. Signal Service, Fort Omaha, Neb., in the capacity of aeronautical mechanical engineer.

A. B. Christen has been commissioned as First Lieutenant, Signal Corps, and will leave shortly for France.

Eugene L. Brown, Jr., has resigned his position with the Illinois Stoker Company, Alton, Ill., to accept a commission as First Lieutenant in the Engineer Officers' Reserve Corps.

Fred W. Brown has been commissioned as Captain in the Ordnance Section of the Officers' Reserve Corps.

Frank B. Gilbreth, consulting management engineer, of Providence, R. I., has been commissioned a Major in the Ordnance Department of the United States Army and is to have charge of some features of construction work of the railroad which the United States is to build in France.

Henry L. Doherty, president of the Doherty Operating Company, New York, is the subject of a biographical sketch in the October number of the *American Magazine*.

APPOINTMENTS

Arthur A. Misch, of Cleveland, O., has been appointed First Lieutenant in the Ordnance Department of the Officers' Reserve Corps.

Robert E. Jackson, formerly assistant superintendent of the Edison Laboratories, Orange, N. J., has been appointed superintendent of the laboratories, effective October 1.

George H. Shenberger has been appointed works and safety engineer for the Goulds Manufacturing Company, Seneca Falls, N. Y.

Christian Girl, president of the Standard Parts Company, Cleveland, O., has been appointed by the Government to supervise the construction of the 40,000 Liberty trucks that are to be built for the War Department. He will remain at the head of the Standard Parts Company, but has been given a leave of absence in order to devote his time to Government service.

William A. Blackburn has been appointed manager of manufacturing at the Cadillac Motor Car Company, of Detroit, Mich., superseding George H. Layng, who has recently become associated with the Lincoln Manufacturing Company, of Detroit, Mich. Mr. Blackburn was formerly connected with the Cadillac Motor Car Company in the capacity of general foreman.

Walter D. Fuller has been appointed secretary of The Curtis Publishing Company, Philadelphia, Pa. He was formerly comptroller of the same company.

George E. Pellissier, consulting engineer of Springfield, Mass., has been appointed assistant general manager of the Holyoke, Mass., Street Railway.

AUTHORS

Allen F. Brewer is the author of an article bearing on Overhead Charges as Applied to Appraisal Reports, published in *Industrial Management* for September, 1917.

H. L. Gantt presented a paper on the Economic Position of the Engineer before the October 22 meeting of the Engineers' Club of Trenton.

John T. Faig addressed the Engineers' Club of Dayton, October 2, on The Economical Use of Coal by Communities.

C. E. Knoeppel, of New York, addressed the October 10 meeting of the New England Foundrymen's Association, Boston, Mass., on The Importance of Foundry Costs.

C. B. Auel has contributed an article on the Utilization of Factory Wastes to the October issue of *Industrial Management*.

Richard H. Rice is the author of The Large Turbo-Generator which appears in the October number of the *General Electric Review*.

Dexter S. Kimball has contributed an article entitled Labor-Maintenance Service as a Factor in Management, to the October issue of *Industrial Management*.

J. W. Ledoux has contributed an article on Purposes Which Should Govern Water-Works Valuations to the October 4 issue of *Engineering News-Record*.

John Hunter is the author of an article on New Boilers for Ashley Street Station which is published in the October 9 issue of *Power*.

C. B. Lord is the author of Athletics for the Working Force, which appears in the October issue of *Industrial Management*.

Roy H. Smith has contributed an article on the Cold-Heading of Wire to the October number of *Machinery*.

Holden A. Evans has contributed an article on Eliminating Unproductive Time to the October issue of *Industrial Management*.

THE NEW BOOKS

ALL books received by The Journal will be listed under this heading, generally accompanied by brief descriptive notes. Works of special importance to mechanical engineers will be commented on at length by members and others peculiarly qualified by reason of their experience and training.

Steam Turbines

Steam Turbines. By Wm. J. Goudie, M.I.M.E., M.I.E.S., Scotland, Reader in Theory and Practice of Heat Engines, University of London. Longmans, Green & Co., New York, 1917. Cloth, 6x9 in., x+519 pp., 230 illustrations. $4.

As stated in the author's preface, the book is primarily designed for the use of engineering students, but from the extensive analyses and the quantity of advanced data and methods of calculation it contains, it will be of considerable use to designing engineers. It will also be very suitable for students and from this point of view is much better for classroom use than Stodola, which is altogether too heavy for anybody but experienced designers, very cumbersome in the classroom and without examples, although it has been considered the standard reference work for many years. Compared with other books now on the market, it will fill a much needed place, in that it is less informal and somewhat more convenient in its treatment than Martin's book and much more thorough in detail than Roe's or Thomas's works on the subject. These latter two books, however, were only intended for classroom use, the former for short courses, such, for instance, as two hours' lecture work a week for a class of senior students covering the course in one term.

The arrangement of the chapters is somewhat unusual. Immediately after the first chapter, Classification of Steam Turbines, follows the description of commercial types. The usual arrangement is to discuss the design of the turbine, as given in Chapters 7 to 15, and then consider the commercial types as examples of the procedure. It seems as if the usual practice were more desirable; what was probably in the author's mind was to teach the student what the commercial types were, using his memory faculty first, following it with the analyses of the commercial types, and using his reasoning faculty after he had become familiar with what the turbine is. However, the writer has found it better, in general, to exercise the memory faculty of the second- or third-year student by general descriptive courses of power machinery, and to handle the design of steam turbines only with fourth-year students, which would render the usual arrangement of design material first and descriptive material afterwards a better one.

In Chapter 7 the material on supersaturated steam is the first that the reviewer has seen which properly elaborates this subject. Information on this peculiar phenomenon has been very scarce. Chapter 10 on mechanical losses and their prevention is also very well worked out and gives some interesting diagrams in connection with the formulæ. Chapters 13, 14 and 15, on the provisional determination of general proportions, help to emphasize the important point in turbine design, namely, that the complete design is practically never worked out at the first trial. Each adjustment of any single dimension in the nozzles and blading affects so many other variables, which in turn react upon the first, that the computations must be completely revamped in order to make the necessary and complete corrections. With the exception of Martin's book, practically no other text has called sufficient attention to this feature.

The description of the Ljungström turbine in Chapter 3 and the design in Chapter 15 are the first published material that the writer has seen fully covering this interesting and novel type of machine. It is to be remembered in working out turbine designs that the number of examples is usually less than in textbooks generally, on account of the length of

[illegible] class of fourth year [illegible] one year, three hours' lecture [illegible], it was found [illegible] the impulse or reaction [illegible]. Most of the examples in this [illegible] nozzle, bucket, or complete [illegible] only. This is very desirable from a practical point of view.

Naturally, a good deal of the material is worked up from previous books on the subject, but there is quite a little new matter, particularly in the sections on provisional design. [illegible] book is the one which it resembles the most, but it carries the design more logically to its conclusion. It covers the field about as completely as any turbine book which has been published up to the present time, and should be a very valuable addition to any engineer's library.

R. J. S. PIGOTT.

Mechanical Equipment of Buildings. Vol. II, Power Plants and Refrigeration. By Louis Allen Harding, B.S., M.E., and Arthur Cutts Willard, S.B. John Wiley & Sons, Inc., New York, 1917. First Edition. Flexible binding, 7x9¼ in., 766 pp., profusely illustrated. $5 net.

An almost ideal book for the mechanical engineer for use as reference is the work under consideration. It cannot be considered an entirely original book, but it is made up of a collection of valuable data that are badly needed and ordinarily hard to find. The information contained is also well assembled and indexed.

To the designing engineer the book is almost indispensable. To the power-plant engineer it is also of great value, and the refrigerating engineer, even if the refrigeration section is somewhat limited, will find that the remainder of the contents on steam-power plant proper is well adapted to his uses.

The first chapter is devoted to physical units and heat, and is valuable especially to the student. This is followed by a section on water, steam and air, dealing with formulæ for measurement, designing of piping, and with the fundamental laws of hydraulics, thermodynamics and pneumatics.

Chapter III takes up fuels and combustion, giving valuable information in small space and including tables of analyses and heating values of various fuels, and also an analysis of fuels and flue gases. The rather complete chapter on boilers and rules for construction which follows contains a number of valuable tables of detail dimensions of various standard boilers, in addition to construction formulæ, and is well supplemented with illustrations and explanations. Following this is a short chapter dealing with mechanical stokers that could well be somewhat more complete.

The next chapter is on superheaters and economizers, giving also manufacturers' tables of tests on performance under various conditions. The part devoted to superheaters is very short, thus throwing the book somewhat out of balance.

The section devoted to the theory, design and construction of chimneys for power boilers is interesting and complete in outline. It not only includes the methods of determining the proper dimensions of breechings and stacks, but also construction data of steel, brick and concrete chimneys, and a complete set of specifications. It is followed by a number of pages on mechanical draft, including tables and curves of forced-draft fan performance, and a chapter on feedwater heaters and purifiers, also a collection of data on feedwater treatment.

The space devoted to steam engines and steam turbines is almost a book by itself, well filled with data in a concentrated form. The chapter on pumps is also an extensive one, and contains some novel information.

The next eighty pages cover quite well the steam condenser and cooling ponds and towers, giving results of tests under various conditions. These data are entirely conservative, and most of them, as throughout the book, have been obtained from responsible manufacturers. A psychrometric chart and tables are also included.

The chapters on pipe fittings, valves, coverings and accessories and power-plant piping are well filled with selected data, and embody specifications for piping under various steam pressures.

The section on the arrangement of steam-power plants is well illustrated with plan and cross-sectional views of representative power plants, and is followed by data on coal- and ash-handling machinery well adapted for medium- and large-size plants.

The cost of steam- and gas-power equipment is treated in a separate chapter containing complete lists of power-plant equipment adapted for small and large plants, together with equations for determining the costs of various sizes.

The information on isolated plants is very valuable to the operating engineers of hotels and other large buildings, also to the electric or heating-plant central-station engineering departments.

The remainder of the book is devoted to refrigeration, but the information given, while very valuable, is not entirely of a novel nature. Illustrations on the construction of cold-storage walls are shown, followed by considerable matter on the heat transmission of piping, Goodenough's tables on saturated and superheated ammonia, and a number of well-arranged pages on the ammonia condenser.

Very interesting and practical material is included in the chapter on the absorption machine, and the subject is treated in an entirely new way. The valuable tables of the York Mfg. Co. and a number of other ice-machinery manufacturers are included.

The book, as a whole, presents well-assembled and properly condensed information in a readily accessible form. The examples found in the various chapters are also of value in helping the engineer to follow easily the calculations of various problems.

VICTOR J. AZBE.

Military Preparedness and the Engineer. A Handbook for the Civilian Engineer. By Ernest F. Robinson, Assoc. M. Am.Soc.C.E., Captain, New York Corps of Engineers, National Guard. Clark Book Co., New York, 1917. Second Edition. Cloth, 4½ x 6½ in., 361 pp., 132 illustrations. $2 net.

This book has been written for the information of civilian engineers desirous of serving their country in the field in time of war, and the author has aimed to present to such men as accurate an idea as possible of the salient points of military engineering. The publication is based on a series of lectures delivered before prominent engineering societies during the past two years, and in the present edition has been brought down to date by the inclusion of new material from many different sources. Much relating to field fortifications has been obtained directly from participants in the European struggle, and is descriptive of types now in actual use. Contents: How to Obtain a Military Training; The National Guard; Military Organization; Military Administration; Engineer Troops in the Field; Fire Action; Field Fortifications; Obstacles; Siege Works; Demolitions; Military Bridges; Topographical Sketching; Wire Entanglements; Organization of Captured Positions; Engineers in Field Service; Sanitation; Equipment Data.

The Thirty-Eighth Annual Meeting of The American Society of Mechanical Engineers will be held in the Engineering Societies Building, New York, December 4 to 7. The program of the meeting, giving details of professional sessions, committee meetings, sections conferences, titles of addresses, titles and authors of papers, etc., is given on pages 1004 and 1005.

Publication of the papers was commenced in the October issue and has been continued in the successive issues; publication in The Journal is in comprehensive abstract form and simultaneously the papers are being printed in extenso in pamphlet form and copies may be obtained gratis by members on request. Contributed discussion of the Annual Meeting papers is solicited and will be presented at the meeting and subsequently published in The Journal. A full account of the Annual Meeting will be presented in the January Issue.

THE COOLING OF WATER FOR POWER-PLANT PURPOSES

By C. C. THOMAS, BALTIMORE, MD.

Member of the Society

THE purpose of the work here described was to ascertain the conditions governing the cooling of water by means of spray ponds. This involved determining the efficiency of the cooling process under varying conditions of pressure at the spray nozzles, the temperature of water to be cooled, the power applied to the pumps, the height of sprays above the pond, etc. The work has resulted in a large collection of data, part of which is presented here, and also in the development of the new form of spraying device described.

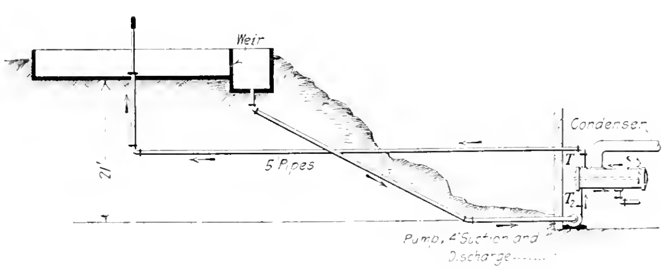

Fig. 1 Cooling System Used in the Experiments

EXPERIMENTAL WORK

The experiments were made on the pond shown in Fig. 1, which is part of the power plant and laboratory equipment of The Johns Hopkins University, Department of Engineering. The pond is 35 ft. in diameter and 4 ft. deep and was designed with special reference to experimental work, as well as to cool the condensing water for a 50-kw. Buckeyemobile fitted with a surface condenser. The water is ordinarily sprayed through one spray head, or nozzle, of the new type described in this paper, but some of the tests were made with nozzles of other types. A motor-driven centrifugal pump with 4-in. suction and discharge sends the water through the condenser tubes and to the spray head, as shown in Fig. 1.

The pressure at the spray head or other type of nozzle was in all cases measured by a mercury column connected to the entrance of the spraying device, and the recorded pressures are for that point. Wind velocity was measured by a standard anemometer, and the humidity by a wet-and-dry-bulb sling psychrometer. The amount of water circulated was measured by a 10-in. weir fitted with a micrometer hook gage.

About six hundred tests have been made, mostly with the new type of spray head shown in Figs. 2, 3, and 4, but tests Nos. 11 to 18, 86 to 91, and many others not reported here, were made with three sizes (3-in., 2-in., and 1-in.) of nozzle having spiral cores, as shown in Fig. 5. Data representative of the tests are given in an appendix.

It was desired to ascertain, among other things, the effect of placing a wire fly-screen cylinder about the spray head, and many of the tests were so made, as shown in the appendix.

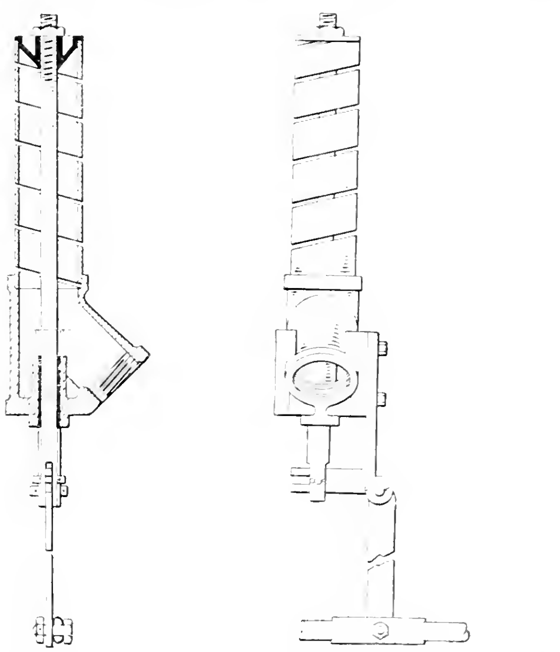

Fig. 2 Thomas Adjustable Spray Head, Closed and Open

THE AUTHOR'S ADJUSTABLE SPRAY HEAD

The adjustable spray head is shown in Figs. 2 and 3. It consists of a cast-iron supporting base containing the water-entry opening and carrying a $3\frac{1}{4}$-in. outside-diameter bronze tube in which is cut a spiral opening of coarse pitch. This opening is cut with a tool placed at an angle of about 60 deg. with the axis of the tube, so that the water is thrown upward at this angle. The spiral tube is held between the base and

For presentation at the Annual Meeting, December, 1917, of The American Society of Mechanical Engineers, 29 West 39th Street, New York. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

a cap which fits the top by means of a central bronze stem which passes down through a close-clearance bushing in the base. This stem is movable and is operated by a bell crank having an extended vertical arm giving accurate control of the position of the stem. The result of the motion is either to increase or decrease the fineness of the film of water as it leaves the spray head. When the head is in operation the water is discharged in a continuous sheet in a direction which

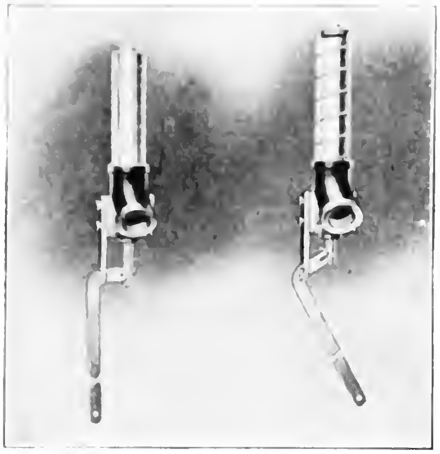

FIG. 3 SECTION AND ELEVATION OF THOMAS ADJUSTABLE SPRAY HEAD

is inclined upward, due to the angle of the spiral opening. As the water film spreads it becomes thinner, on account of its increasing diameter, until a point is reached where the surface tension is overcome and the sheet of water breaks into either a uniformly fine spray, a mist, or a large number of small drops, depending upon the size of opening to which the spray head has been adjusted. This principle of spraying a liquid as the result of the spreading of a film of water until it breaks into mist, or spray, or fine drops, is particularly applicable to low-pressure work, and it will be noticed that the pressures used in the experiments described are relatively low, being in general from 5 to 8 in. of mercury. A pressure of 10 in. gives an exceedingly fine spray, and in general 8 in. at the spray head is ample. Of course, the higher the pressure, the more extensive is the cooling, and this is true with all forms of nozzle.

EFFICIENCY OF COOLING PONDS AND TOWERS

The efficiency E of a cooling pond or tower may be expressed as the ratio between the cooling actually produced, $T_1 - T_2$, and that which would have resulted from cooling the water down to the dewpoint or wet-bulb temperature T_w. Thus,

$$E = \frac{T_1 - T_2}{T_1 - T_w}$$

T_1 and T_2 being the temperatures of the water before and after cooling, respectively. A perfect atomizing device would be one capable of subdividing the water so that evaporation would take place at T_w, and to an extent such as to lower the temperature of the remaining liquid spray to that temperature.

The curves in Figs. 6 and 7 show variation of efficiency of the adjustable spray head with variation of pressure and with variation of capacity, respectively, for three initial temperatures, namely, for $T_1 = 95$, 105 and 125 deg. fahr. These results were obtained by adjusting the spray head to suit the weather conditions existing at the time. From these curves the cross curves on Fig. 8 were drawn, for use in predicting the cooling range to be expected from a given set of conditions. This may be done as follows:

From these curves the efficiency to be expected for any given initial temperature T_1 and for any given pressure at the nozzle, may be found. If an initial temperature of water, T_1, and an average air temperature, T_a, and humidity be assumed for the locality of the cooling pond, the expected cooling range may be worked out. For example, if $T_1 = 115$ deg. and $T_a = 70$ deg. and if humidity $= 0.55$, then, from a humidity table, $T_a - T_w = 10$ deg. or $T_w = 70 - 10 = 60$ deg., and

$$T_1 - T_w = 115 - 60 = 55 \text{ deg.}$$

Let the pressure at the nozzle be 10 in. mercury. From the curves, the efficiency to be expected in cooling water from 115 deg. by spraying it with 10 in. mercury pressure at the nozzle is

$$\frac{T_1 - T_2}{T_1 - T_w} = 0.70$$

The cooling range will then be

$$T_1 - T_2 = 0.70\ (T_1 - T_w) = 0.70 \times 55 = 38.5 \text{ deg.}$$

FIG. 4 THOMAS ADJUSTABLE SPRAY HEAD IN OPERATION

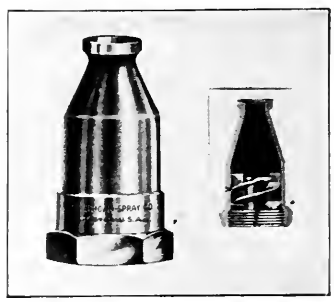

FIG. 5 NON-ADJUSTABLE NOZZLE WITH SPIRAL CORE

It is of interest to observe the wide variation of efficiency shown in Fig. 9 which takes place during a long period of operation when no attempt is made to adjust the spray head so as to obtain uniformly good results. The tests yielding these points cover about a year. The heavy black circles indicate results from the non-adjustable nozzles, while the others refer to the adjustable spray head when operated under widely varying weather conditions, pressures, and temperatures of water, without any attempt to obtain high efficiency. It will be noticed that with the non-adjustable nozzles, such as shown in Fig. 5, the pressures used are high and capacities very low as compared with those for the adjustable spray head.

Fig. 10 shows for a few related tests the variation of cooling range, $T_1 - T_2$, with pressure at the spray head.

A curve was obtained showing better efficiencies with the

water falling upon the bare cement bottom as compared with those resulting when the pond contained its normal amount of water. These results are rather surprising, and it is hoped that further tests may be made to confirm or to controvert them. If a bare pond would serve as well as one containing water, the construction of the pond could be cheapened, since less weight would come upon the foundation and less material would be required for the pond as a whole.

FACTORS INVOLVED IN THE PROBLEM OF COOLING WATER

The loss due to evaporation during a period of eight days is shown in Table 1. These data are not yet complete, but the average evaporation may probably be taken as about 2.25 per cent. This will, of course, vary with weather conditions, initial temperature of water, pressure at the nozzle, and with humidity. A large number of tests made with water at high

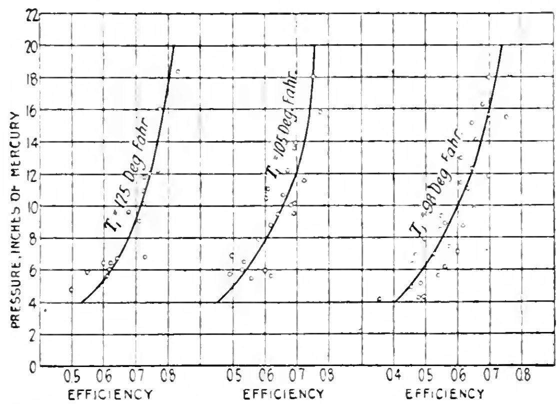

FIG. 6 VARIATION OF EFFICIENCY OF ADJUSTABLE SPRAY HEAD WITH VARIATION OF WATER PRESSURE

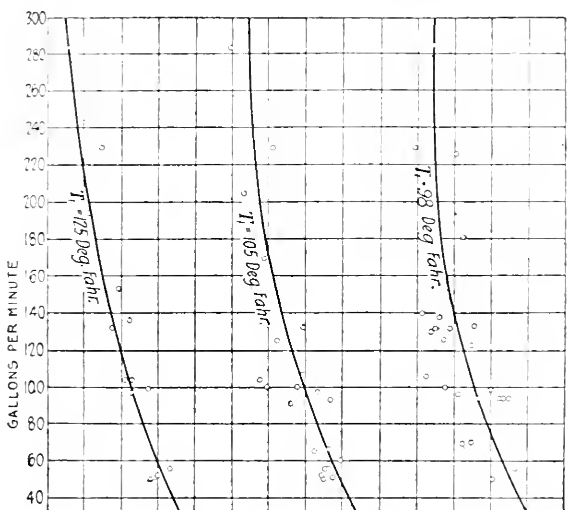

FIG. 7 VARIATION OF EFFICIENCY OF ADJUSTABLE SPRAY HEAD WITH VARIATION OF CAPACITY

and low initial temperatures indicate that 2 to 2.5 per cent per hour represents fairly well the average loss of water, but that it may be as low as 0.30 per cent, and in windy weather as high as 10 or 15 per cent with non-adjustable nozzles.

Extended observations on a pond at Sparrow's Point, Md., for cooling gas-engine-jacket water show the average loss in 24 hours to be 6 in. depth of water. The pond is 60 ft. x 40 ft. and the water circulated amounts to 2000 g.p.m. The loss is therefore about 0.31 per cent per hour.

The upper left hand point in Fig. 11 was obtained from tests on this pond.

The power required to circulate the water is shown in Fig. 12, as watts per gallon per minute per degree of cooling, from varying initial temperatures. In order to test the accuracy of this curve, experiments were made on the pond at Spar-

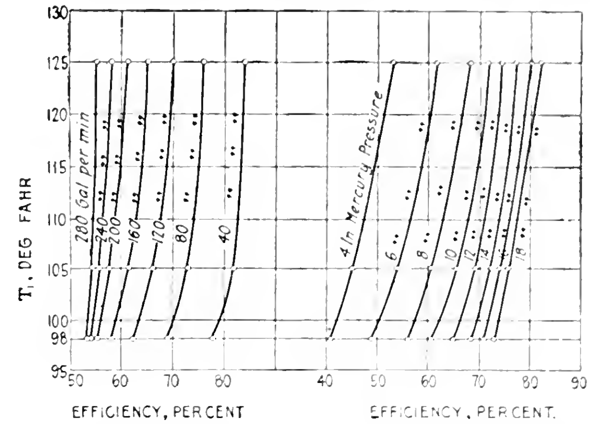

FIG. 8 CURVES FOR PREDICTING COOLING RANGE TO BE EXPECTED FROM A GIVEN SET OF CONDITIONS

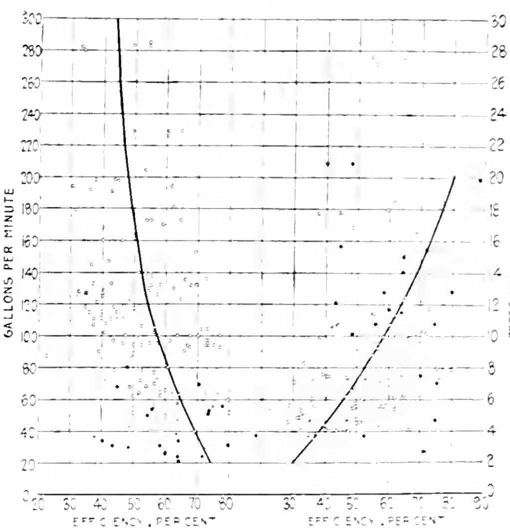

FIG. 9 CURVES SHOWING WIDE VARIATION OF EFFICIENCY WHEN PROPER ADJUSTMENT OF SPRAY HEAD IS NEGLECTED

(Black circles indicate results from non-controlled nozzles)

row's Point, which is equipped with two sets of nozzles, either of which may be used. One set consists of 42 non-adjustable, spiral-core nozzles, and the other set of 12 of the adjustable spray heads described in this paper. The power required with the adjustable spray heads at Sparrow's Point is shown by the point so marked in Fig. 11, the other points being from the Johns Hopkins pond. From this curve the power required to circulate the water in a given case can be estimated, to cover specified temperature and capacity. The power appears to be practically independent of the type of spraying device used. The average power required to drive the pump may be calculated from the following equation representing the curve drawn through the experimentally determined points in Fig. 11:

$$P = \left(\frac{100}{T_1}\right)^{3.25}$$

[illegible] power of the pump motor in watts per gallon per minute per degree Fahrenheit of cooling, and T = initial temperature of the water to be cooled, deg. fahr. (not absolute temperature). The cooling seems to be principally dependent upon the energy put into forcing the water through some suitable [illegible], and given the requisite energy a great variety of forms of nozzle would yield about equally good results. The operating advantages of the adjustable spray head and its large capacity greatly facilitate keeping the heads clean without shutting down to clean them. It also permits

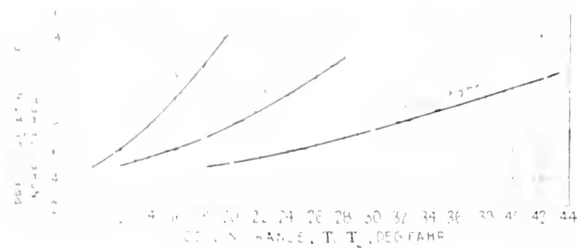

FIG. 10 VARIATION OF COOLING RANGE, $T_1 - T_2$, WITH VARIATION OF PRESSURE AT THE SPRAY HEAD

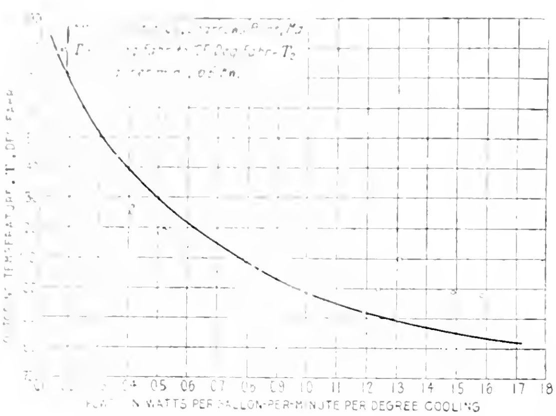

FIG. 11 POWER REQUIRED TO CIRCULATE WATER IN COOLING SYSTEM FROM VARIOUS INITIAL TEMPERATURES

regulation of the spray to suit weather conditions and to minimize loss of water and inconvenience to the nearby buildings due to driftage in windy weather. The amount and cost of piping are comparatively small for the adjustable spray head, since each one will handle from 150 to 250 gal. per min. In general, each adjustable spray head will handle the condensing water for a 50- to 75-kw. plant.

Curves are also shown in the complete paper of the effect of wind velocity upon the cooling range, the effect of spraying upon a series of superposed inclined cement plates, and of the cooling range as affected by the amount of water sprayed by a given adjustable spray head. The factor of height of spray nozzles above the surface of the pond is also considered.

It has been found to be very difficult to take account of all the variables involved in the problem of cooling water, and perhaps no one formula will cover the matter completely. It is hoped that further investigation will serve to define the [illegible] humidity and wind velocity and some of the other [illegible] that this paper may perhaps stimulate others [illegible] complete work than the writer has been able to [illegible].

CONCLUSION

[In his conclusion, the author considers other methods of cooling water, and compares the results with those obtained from spray ponds.

Fig. 12 shows a cooling pond equipped with adjustable spray heads for 2500 kw. capacity of turbines.]

The experimental pond shown in Fig. 1 was built in 1914 for the dual purpose of serving the University power plant and permitting investigation of the problems discussed in this paper. The writer has had much assistance from others, and is particularly indebted to Mr. W. J. Dana, Instructor in Mechanical Engineering, Johns Hopkins University, to Mr. John P. Powell, Superintendent of Gas Engines, Bethlehem Steel Company, Sparrow's Point, Md., and to the C. H. Wheeler Manufacturing Company, Philadelphia.

TABLE 1 TESTS WITH ADJUSTABLE SPRAY HEAD, AT LOW PRESSURE AND AT LOW INITIAL TEMPERATURES, TO ASCERTAIN LOSS OF WATER DUE TO EVAPORATION

Test number	1	2	3	4	5	6	7	8
Date, 1915	9-27	9-28	9-29	10-3	10-4	10-5	10-6	10-8
Duration of test, hours	6½	6½	4½	8	8	8	6	8

Hook gage, first reading, ft	1.593	1.592	1.592	1.577	1.571	1.597	1.598	1.511
Hook gage, last reading, ft	1.567	1.570	1.582	1.571	1.552	1.584	1.545	1.481
Loss on hook gage, ft	0.028	0.022	0.010	0.006	0.019	0.013	0.053	0.030
Pressure at nozzle, in mercury	4.27	6.10	3.00	5.24	6.74	6.23	6.59	5.10
Temperature at inlet, T_1, deg. fahr	86.0	83.5	84.0	73.9	79.6	81.6	70.3	80.0
Temperature from pond, T_2, deg. fahr	80.4	77.8	78.0	70.6	73.6	74.3	64.6	70.2
Cooling range, $T_1 - T_2$, deg. fahr.	5.6	5.7	6.0	3.3	6.0	7.3	5.7	9.8
Dry-bulb temperature, T_d, deg. fahr.	75.8	75.7	76.0	69.6	75.2	73.1	59.4	63.5
Wet-bulb temperature, T_w, deg. fahr.	66.6	68.2	66.0	57.1	62.0	61.9	50.1	56.5
Depression, $T_d - T_w$, deg. fahr.	9.2	7.5	10.0	12.5	13.2	11.2	9.3	7.0
Humidity, per cent.	62	70	60	46	47	53	53	65
Loss of water,[1] per cent per hour	2.49	1.99	1.30	0.483	1.59	0.934	4.99	4.11

[1] Average loss of water (8 days), per cent per hour, 2.23.

The average efficiency for the 8 days covered by the above tests is 32½ per cent, and this will be seen to correspond with the 6-in. pressure curve (extended) in the T_1 and efficiency curves on Fig. 8. With such low initial temperatures and pressures this represents the efficiency and cooling range to be expected.

FIG. 12 COOLING POND WITH ADJUSTABLE SPRAY HEADS FOR STATION OF 2500 KW. CAPACITY

A COMMERCIAL ANALYSIS OF THE SMALL-TURBINE SITUATION

By W. J. A. LONDON, SPRINGFIELD, MASS.

Member of the Society

This paper is devoted to a commercial analysis of the four types of small steam turbines now on the market and used for the driving of auxiliary machinery, dealing principally with non-condensing units.

In these, high thermal efficiency is in many cases unnecessary on account of economic utilization of the exhaust steam, and as economy bears a definite relation to first cost, a highly efficient machine is often a mistaken investment. Moreover, operating conditions are generally such that the designer must sacrifice considerations of efficiency if they interfere in any measure with simplicity and durability.

The theoretical design, according to the author, presents no difficulties, but the mechanical design is what determines success or absolute failure; and some of the problems involved and the methods that have been employed in solving them successfully are indicated.

The average specification calls for very rigid guarantee as to steam consumption, speed regulation and load requirements that, in the opinion of the author, are in most cases unnecessarily severe and merely tend to increase the cost of installation. After an extended survey of the situation, he has been led to formulate a Code of Practice, given in an appendix to the paper. The adoption of this code would, he believes, bring about a reduction in selling prices, eliminate many of the unpleasant experiences which now often arise between manufacturers and customers, and thereby increase the popularity of the turbine-driven unit.

EIGHT years ago the Society was presented with a very valuable and complete paper,[1] by Mr. George A. Orrok, Mem.Am.Soc.M.E., on the small-turbine situation at that time. A great deal of further development has naturally taken place since then, changed operating conditions calling for considerable modifications in design. Increased competition, and a broader conception of the possibilities and limitations of various types, have resulted in a gradual elimination of certain principles of operation and a general trend toward the adoption of one common type.

We have seen during the last six or seven years a very marked tendency toward standardization of type in the larger machines. Practically every builder has resorted to the *composite* type, i.e., multi-velocity staging in the high-pressure element, and pressure staging at the low-pressure end. Even such a zealous advocate of the *pure* type as Parsons himself has now been converted to the advantages of this type, and is building the composite machine.

The same condition exists in the field of small machines, and it is interesting to review the various designs as mentioned by Mr. Orrok in 1909,[1] and to see which have survived the test of time and experience; and among the ones that have survived to note the modifications that have been made to suit present practice.

In the order given we find: (1) *De Laval,* (2) *Terry,* (3) *Sturtevant,* (4) *Bliss,* (5) *Dake,* (6) *Curtis,* (7) *Kerr,* (8) *Wilkinson.* These may be conveniently classed in general types as follows: (*a*) *De Laval;* (*b*) *Terry, Sturtevant* and *Bliss;* (*c*) *Dake;* (*d*) *Curtis;* (*e*) *Kerr;* (*f*) *Wilkinson.*

The Bliss, Dake and Wilkinson are either no longer on the market or are not seriously competitive; Sturtevant and Kerr still manufacture their original types only, with minor modifications; but De Laval and Terry have both recently developed machines on the Curtis principle. As these latter firms are two of the largest manufacturers of small turbines today, it would appear that there are sound reasons why they should depart from their original designs, and this fact is indicative of the general trend toward standardization mentioned above.

Since Mr. Orrok's paper, five new machines have appeared on the market. They are the Westinghouse; the Allis, Chalmers & Wait, reviving the Wilkinson principle as described by Mr. Orrok; the Lee, manufactured by the Witton Co. of New London, Conn., which is a modified Terry machine; the Alberger, an unmodified Curtis—in fact, manufactured under license from the General Electric Co., and hardly to be considered as a separate machine; the "Steam Motor," also a Curtis type, and the Moore, a modification of the Kerr machine. We have, therefore, at the present time the following types to consider: (1) The *Terry,* which includes the Sturtevant and Lee machines; (2) the *Westinghouse,* which includes the Allis, Chalmers and Wait machines; (3) the *Curtis,* which includes the machines manufactured by the G. E. Co., Terry, De Laval, Alberger, The Steam Motors Co., and Moore, and (4) the *Kerr* type, manufactured by the Kerr Turbine Co. and the Moore Co.

The machines in the first three groups employ velocity staging, and in small machines are, for the most part, single-stage, and will be considered as such for comparative purposes. Some of the designs are, of course, arranged for "staging," to improve the economy, but as this does not effect our considerations when comparing the relative merits of the general types, all machines in this class will be assumed to be of the single-stage type. The Kerr machine, primarily based on the pressure-staging principle, must be considered separately as a multi-stage machine.

As the title indicates, this paper is devoted to a purely commercial analysis of the various designs and the situation in general, and will deal particularly with non-condensing units. The thermodynamic features will be barely touched upon, except in cases where they have a direct bearing on the commercial aspect.

[1] Small Steam Turbines, George A. Orrok, Trans. Am.Soc.M.E., vol. 31 (1909), p. 263.

For presentation at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December 4 to 7, 1917. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

THREE ASPECTS OF THE SITUATION

There are three distinct aspects to this situation, namely:

(1) The type to be employed that will give the necessary competitive efficiency, with the lowest shop cost to the manufacturer, together with a design that will give satisfaction to the customer after installation.

(2) The aspect from the salesman's and customer's point of view. This governs the rating or maximum output of the machine, standardization of specifications, etc., as well as the proper appreciation of efficiency, with its relation to first cost. This latter phase is, perhaps, better explained by stating that in many instances water rate efficiency can be economically sacrificed in favor of first cost, and vice versa.

(3) The policy of the manufacturer who builds one part of the apparatus (such as the turbine) toward the manufacturer of the other (such as the pump), and their united policy toward the customer.

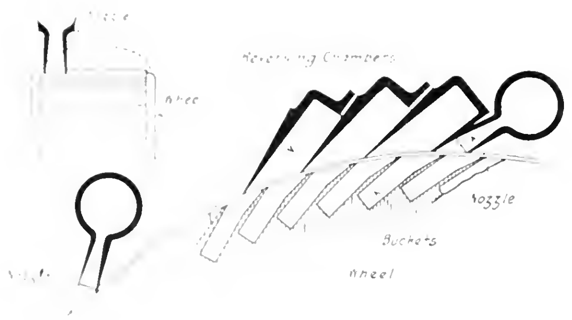

Fig. 1 Terry Type Turbine

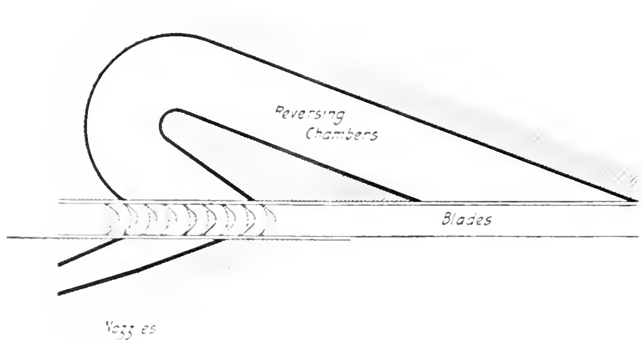

Fig. 2 Westinghouse Turbine

[The paper here enters into a detailed consideration of the three aspects. The introduction to the author's discussion of type for efficiency, being necessarily of a mathematical nature, is not abstracted here, but only his conclusions given. His treatment of the second and third aspects is here given practically in full.]

CONSIDERATION OF TYPE FOR EFFICIENCY

It is now generally acknowledged that from a design standpoint the small machine must be laid down on a totally different basis to the larger machines. The principal reasons for this are:

a High thermal efficiency is in a great many cases unnecessary on account of the economical utilization of exhaust steam; and as economy bears a definite relation to first cost, a highly efficient machine is often a mistaken investment.

b The class of labor employed in the average station to look after auxiliaries is very inferior to that employed on the main engine room floor. These machines, which are called upon for continuous operation, are often located in places where no other well-finished piece of machinery would be expected to run.[1] The designer must therefore consider simplicity and durability first, with as high an efficiency as possible; but he must sacrifice efficiency if in any measure it will interfere with the first essentials mentioned.

While the small-turbine auxiliary has all the appearance of a very elementary and simple engineering proposition, this is by no means the case, as any manufacturer knows; and problems equally complex with those confronting the designer of large machines have had to be solved, and a great many are by no means solved yet. We have only to consider the comparatively few firms that are competing in this line today with the number that have entered it, evidently tempted by the apparent simplicity and big profits, and finding out too late that it is a more difficult proposition than appears on the surface. The theoretical design, that is, the proportions of nozzles, blades, wheels, etc., presents no difficulties, but the *mechanical design* of such parts as the bearings, glands, governor, etc., is what determines success or absolute failure.

It is not within the province of this paper to go into these details any further than to point out in a general way some of the problems that have had to be solved. Among the more important of these are lubrication, packing and regulation.

Forced lubrication being impracticable in small machines for general-auxiliary purposes, the ring-oiled type has been called upon to operate with duties previously considered impossible, and to operate continuously with a bearing-box temperature in the neighborhood of 250 deg. fahr.

Glands or stuffing boxes are sometimes called upon to pack against a back pressure of 120 lb., while 20 and 30 lb. are common. It must be borne in mind that the soft-packing stuffing box as used in reciprocating machines is impracticable in turbine work on account of the high rubbing speeds.

The design of a satisfactory governor, the essential feature of which is simplicity, but, having a characteristic approaching the more elaborate types, has presented many difficulties; so has the governor valve, which must be as small as possible to minimize cutting at light loads, but must not crowd or stick when it is passing the maximum amount of steam required.

The above constitute the essential components governing details of the performance of the turbine itself, but there is one other and a vital factor to be considered, and one that comes directly within the present subject matter—the satisfactory performance of the whole unit. As in all other classes of machinery, certain mechanical troubles will always arise from time to time, but it is safe to say that today the general behavior of a turbine unit will compare very favorably with that of any other piece of apparatus in a power house. But to return to the more general considerations of the unit as a whole, there are some very important factors to be taken into account that are peculiar to this class of apparatus, and which have a direct bearing on the general design.

The most important of these is, of course, the necessity for true alignment. Where the unit is built in one shop the designer has a distinct advantage, inasmuch as he can so design

[1] Several cases are on record where machines have actually run for considerable periods under water without damage.

both ends of the apparatus as to make one rigid unit; but where the two ends of the unit are built by different parties it is a different proposition.

The average so-called flexible coupling will not satisfactorily take care of mis-alignment, the bedplate cannot be commercially designed that will stay true from test floor to foundations, so that no matter what care has been taken in the shops, a realignment after erection becomes an unfortunate necessity in even the smallest units. There is an extensive field for improvement in general design to eliminate this. Various schemes have been advanced recently resulting in a marked improvement in this direction, such as the 3-point support, and the 3-bearing unit with the elimination of the flexible coupling. The latter is practicable where one firm builds the whole unit, but otherwise up to the present it has not worked out very satisfactorily. The main reason for this is best explained in the case of electric-generator units. If the turbine maker takes away one of the generator bearings, in other words, disturbs the assembly of the complete generator as shipped from the manufacturer, he disclaims responsibility for anything that may happen to that part of the apparatus on the road.

In blower work the proposition is more practicable, but only when the unit is lined up by the turbine maker or one equally appreciative of the necessity of accurate workmanship.

To overcome this trouble, the Steam Motors Co. have recently placed on the market a design of machine as shown in Fig. 5. This machine is supplied with only one bearing and solid coupling for connecting to the driven apparatus. By taking a standard pump or blower and removing one bearing and fitting a solid coupling to the shaft, the combination of steam motor and pump becomes a 2-bearing unit, with a very much shorter bedplate and the elimination of any mis-alignment troubles.

In larger machines, one of the most pleasing in effect and at the same time most radical departures made in recent years to overcome the difficulties of mis-alignment, was the introduction by Mr. R. H. Rice, Mem.Am.Soc.M.E., of the General Electric Co., of the so-called rigid-frame design. From Fig. 6 it will be seen that the bedplate has been entirely eliminated, and the whole structure so designed that both ends are bound to stay in line irrespective of foundation conditions, so reducing the personal equation in erection to a minimum. In erecting this machine only one end is anchored, as shown in Fig. 6. The generator end is mounted on a sliding key, allowing free movement endwise, and on a narrow transverse foundation plate on which the generator can rock to compensate for any vertical movement of the turbine due to varying temperature. In effect, the machine rests on its foundations, as shown diagramatically in the figure.

THE SALESMAN'S AND CUSTOMER'S ASPECT

What might be called the truly commercial aspect of this situation, i.e., those phases of vital interest to the salesman and customer, presents many interesting problems. To begin with, we must forget that we are dealing with steam turbines in the sense that we have been accustomed to, when we have only been considering prime movers. For auxiliary purposes the small turbine is becoming the standard method of drive. That means that it is getting into the class of the electric motor. It has already passed the stage of being "built," and is now being successfully manufactured in quantity.

There is, however, still a great deal to be accomplished before the machine can be satisfactorily manufactured to be sold from stock. At first sight it might appear that this is almost out of the question, especially when we see such a diversity of specifications as accompany the average contracts for small turbines today, but when the number of these machines that are now being turned out at the present time and the fact that the market is increasing rapidly are considered, it is surely only a matter of time when some form of standardization will be absolutely necessary. In the electrical industry we have seen the wonderful advantages, both to the manufacturer and customer, of the rules laid down by standardization committees, and we wondered why we had not adopted them

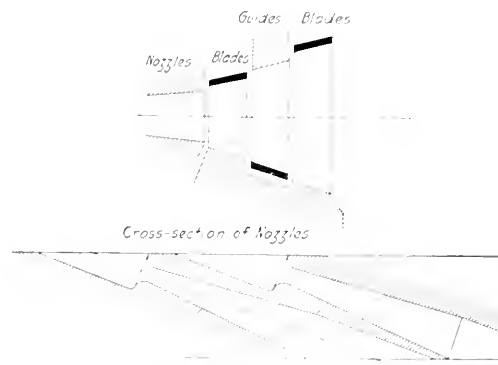

Fig. 3 Curtis Turbine

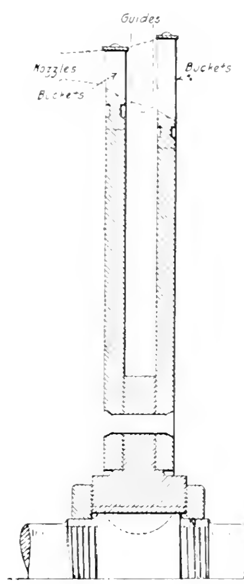

Fig. 4 Kerr Built-Up Wheel

sooner. Perhaps not to the same degree of perfection, but certainly to some extent a standardization of small-turbine specifications is not only possible but quite practicable. As long as the customer calls for something special and everybody is willing to build it, not only does this customer have to pay for it, but the standard machine will cost more on account of the interruption to the manufacturer in putting through lots.

Let us then consider where the possibilities lie in this direction, analyzing the various requirements of the average specification which call for rigid guarantees under the headings: (*a*) steam-consumption guarantees at certain loads with fixed or various steam conditions; (*b*) speed-regulation guarantees,

(c) when connected to electric generators voltage regulation [illegible], and (d) various load requirements and [illegible] steam and back pressure conditions. In addition there is a diversity of requirements as to fittings, such as [illegible] regulator, emergency governor, strainer, etc.

[illegible] (a), this is a much-debated point when discussing small turbines. Granted there was a time when the small turbine was wasteful of steam, that time has nevertheless passed and the builder of small turbines today meets any guarantee he makes, and at the very worst it is questionable whether a small turbine was ever built that consumed steam at a rate comparable with some direct-acting pumps. But there was never any serious criticism raised with such pumps on that score, nor was the manufacturer even asked for a guarantee. The consulting engineer or purchaser feels that he cannot possibly buy a steam turbine, no matter how small, unless he imposes numerous stringent guarantees as regards steam consumption. The fact that an auxiliary rarely operates under

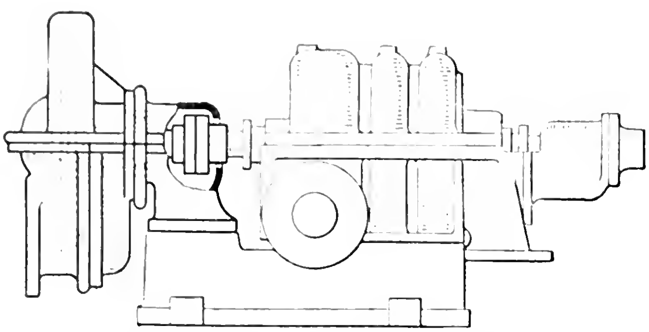

Fig. 5 Pump and Overhung Turbine

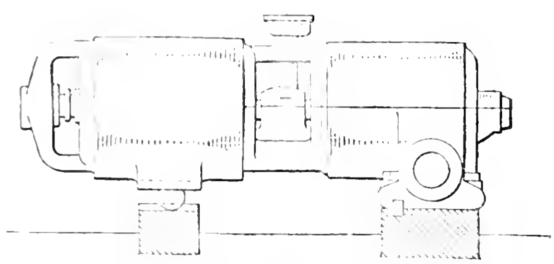

Fig. 6 Rigid-Frame Design Turbine and Pump

the steam conditions as specified, and therefore the guarantees as made bear but little relation to the actual performance, does not enter into his consideration at all.

When a manufacturer advances any argument relative to the unimportance of steam consumption, he is generally misunderstood. The customer feels he is trying to evade any responsibility along these lines and sell an inferior piece of machinery. Let us look at that from another standpoint. The manufacturer today builds one line of machines. There are so many cases where efficiency is of prime importance that the machine as built must be capable of meeting the guarantees as demanded by the market. Furthermore, any machine with a witness-test clause added on cannot be put through the shops independently, but must necessarily be one of a lot of identical machines. If this machine meets its guarantees on test, it is only fair to assume that the others [illegible]. In this connection, a concern which manufactures machines for the U. S. Government under specifications that are most rigid as regards performances on test, yet, with the possible exception of material inspection in some cases, these machines are standard in all respects.

Witness tests are costly. The manufacturer naturally cannot notify the customer exactly when a machine will be ready for the shop tests, and would not want him present then if he did, so that any delay in a busy shop awaiting the customer's convenience and a duplication of the tests must eventually be paid for directly or indirectly by the purchaser.

One more word on the absurd multiplicity of guarantees sometimes called for. It is no exception to find in some propositions, particularly from pump companies, a request for 15 or 20 guarantees under different conditions for a non-condensing machine where the exhaust is to be used in the feedwater heater.

Clause (*b*), speed-regulation guarantee, is necessarily of vital importance in such work as generator drive, but it surely is of no importance whatever when the speed of the turbine is primarily governed by a pressure regulator as in the case of a boiler-feed pump or forced-draft set controlled in a similar manner, yet the manufacturer has to religiously put in his 2 per cent clause.

Even with generator drive, the average clauses are too exacting for the good of the customers. Why need we specify a close speed variation when we already specify a certain variation in voltage? The compensated-wound generator can give flat compounding with a big speed variation, and a reasonably large speed variation means stable governing, whereas a sensitive governor means instability and a tendency to hunt. We have only to look at the average a-c. machine to realize how essential a reasonably wide speed variation is for satisfactory parallel operation.

Again, to obtain close speed variation on test means very delicate fitting and adjustment of the governor valve. The valve must shut absolutely tight, and any valve built this way is subject to cutting in service; whereas, if a wider speed variation had been permissible in the first instance, a more durable valve could have been installed.

Regarding (*c*) load requirements, there is a strong tendency to introduce the *maximum rated* standard into the small-turbine field, and common sense tells us that it is the only proper competitive basis; but is the adoption of this standard commercially practicable under existing conditions? As far as the turbine itself is concerned there is no argument, the output can be accurately estimated; but does the same degree of certainty exist among the pump and blower makers?

With the repeated changes in design, the limited testing facilities in the average pump-maker's plant and the almost impossible proposition of making accurate blower tests on a commercial basis, is it feasible at the present time to order a turbine without an overload margin to take care of errors that are not only excusable but are to be reasonably expected? Experience tells us that a certain leeway *is* necessary. The turbine maker knows this, and often finds that the addition of another jet, over and above that necessary to meet the contract, is a good investment. This principle is not right if we are to have fair competition among turbine makers; it is only natural that the pump maker will favor the type of machine that *he knows* will give him a good big overload. The worst feature of this situation is the fact that in some cases in a cut-price job the pump maker has *relied* on the overload capacity of the turbine to give full load at the pump.[1]

[1] A representative of a pump manufacturer was once frank enough to admit that a certain turbine firm always got the preference because it was more liberal with its overload capacities.

The adoption of the maximum-rating standard by *all* turbine makers and their rigid adherence to it would, in a great measure, solve this whole problem. Granted that allowances are necessary, they should all be made by the pump or blower maker, who should be the best judge as to the leeway advisable, and he should order his turbine accordingly.

The question as to whether the maximum rating will be satisfactory to the customer is another matter to be considered. With the customer educated to the limitations of the turbine there should be no difficulty; but as long as he thinks it can be loaded up to breaking-down point like a motor, there will be dissatisfaction if the machine fails to carry full load when the steam pressure drops. All that is necessary in this case is a clear understanding between the contractor and purchaser as to the conditions *necessary* to obtain full load.

It might be well to bring out here an important point in connection with non-condensing auxiliaries that run at full load continuously. With a condensing machine considerable variations in initial steam pressure can take place without materially affecting the output, but in a non-condensing machine a multiplicity of small deviations from the contract conditions, each insignificant in itself, can have a very marked effect on the output, as will be seen from the following table, which compares the conditions, as they would be specified in an average contract, with conditions that could reasonably be expected in service:[2]

	Steam press., lb.	Quality.	Back press., lb.	Hp.
Specified conditions.........	150	100%	0	100
Operating conditions........	140	98%	2	83

With a view to setting forth how the theories mentioned above can be worked out in practice, a suggested Code of Practice is given in an Appendix.

The question of steam consumption, with its true relation to the overall efficiency of the plant, has lately been receiving much more attention than formerly. In stations and industrial plants where all the exhaust can be utilized, the thermal efficiency of the auxiliaries can vary very considerably without an appreciable effect on the coal pile. Fig. 3 shows what a relatively small effect a very large range in water rate has on the heating value of the exhaust steam.

However, in stations where there are times when all the exhaust cannot be economically utilized, the question of the auxiliary efficiencies becomes of serious importance. To meet this condition a great many radical changes have been made in the general layout of this part of the apparatus, particularly in the introduction of gear-driven pumps, etc., in place of the low-speed, direct-connected type. Any innovation of value here naturally means complications, in the same manner that any marked improvement in the steam consumption of the turbine itself must necessarily be made at a sacrifice of simplicity. Can we afford to do this? Will the little saving that at best can be made commercially in any design of small turbine give the net result required? Is it not better to accept the best efficiency conducive to maximum simplicity and reliability, and be content with that; then, when the point is reached where more exhaust than that supplied by a certain number of auxiliaries is required, to switch over to electrically driven apparatus? The combination steam- and electrically-driven unit meets this situation admirably.

[2] In this connection it might be well to enlarge on one point often overlooked by the manufacturer and customer alike, the necessity for very liberal allowances in machines operating at very low pressures. Operating with atmospheric exhaust an initial drop in steam pressure of 10 lb. from 150 lb. means a reduction of available B.t.u. at the turbine of 3 per cent, whereas the same drop at 60 lb. (common in sugar refinery work) means over 10 per cent. Therefore velocities permissible under the higher pressure must be considerably cut down when it is desired to maintain full load at around 60 or 70 lb.

The ideal way to distribute the units would be to begin with the turbine units in all places that receive the least attention, and such places as boiler-feed pumps, that must not be shut down in case of any electrical disturbance, and keep the electrically driven units on the main engine-room floor as far as possible.

THE MANUFACTURER'S POLICY

Regarding the question of policy between the manufacturer of the respective parts of a complete piece of apparatus and the combined policy of manufacturers toward the customer, the first question that arises is why should there be any difference here from the policy adopted in other branches of the trade. Theoretically, of course, there should be no difference, but many conditions, unfortunately, exist, peculiar to this business, that make this question of policy a very vital one and worthy of serious consideration in any attempt to solve the commercial problem under consideration. When an engine-driven or motor-driven set is sold, the correspondence between the respective manufacturers consists of an interchange of formal orders; but we have a long way to go before we arrive at the same businesslike procedure in connection with turbine units.

These arguments, of course, do not concern the builder of the combined unit, who in this respect will always have a distinct advantage over the other manufacturers.

Any standardization along the lines suggested above will do more than anything else toward clearing the atmosphere of such questions as the limitations of apparatus furnished, the long interchange of correspondence relative to unimportant partial-load performances, and the responsibility for imperfect erection at the customer's plant.

Our one idea in all these considerations is the ultimate reduction of factory costs. Selling costs do not enter into this argument. Factory costs consist of two essential items—manufacturing expenses and overhead. Standardization and the elimination of special machines will help our shop costs or manufacturing expenses. The next question is, What can be done to reduce overhead expenses? To the layman it would appear that the latter should consist of the merest clerical work in such a simple apparatus as a small turbine, but there is today, in addition, a very heavy expenditure that must be borne by all manufacturers alike, and that is the maintenance of a trouble force in the engineering department at the works as well as outside, out of all proportion to the legitimate requirements of the situation. It is here where the question of policy comes in, and it is here where we can look for one of the biggest economies.

There is a deplorable lack of coöperation existing at the present time between the average turbine builder and many of the pump and blower builders. If a unit is reported unsatisfactory for any reason after erection, and the report goes to the pump builder, he will almost invariably assume the said trouble is entirely the fault of the turbine, and call upon the turbine maker to send a man to remedy it before he makes any investigation as to the performance of his own apparatus, and vice versa, if the original report goes to the other party. Even at the station it is common practice for the representative of one end of the apparatus to go out of his way to explain to the customer in detail how the trouble is entirely up to the other end, and this state of affairs is by no means confined to the erecting staff, who cannot always be blamed for taking this attitude, but to the higher officials of the company, who ought to know better. This state of affairs does not help

the customer, but it goes a long way toward making him buy the complete outfit from a firm manufacturing the whole unit. These conditions may, to a certain degree, be expected, but surely it is possible to formulate some definite line of procedure that will, in a great measure, relieve this present unsatisfactory situation.

One of the prominent obstacles to the application of any hard and fast rule is the fact that firms cater to the larger corporations, and feel that it behooves them to go to unjustifiable expense in case of trouble to keep in their good graces for future business. A sound and uniform policy on the part of all manufacturers would put each one in a much stronger position.

A few suggestions as given below present themselves at this time, each one of which, if adopted by one or two individual firms, would probably result in serious disaster, but if conscientiously adopted by all firms would undoubtedly have a mutually beneficial result.

If a turbine is bought by a pump or blower maker, said purchaser must accept the machine on leaving the maker's works as having met all its guarantees (as in the case of reciprocating engines and motors). If, however, subsequent performance warrants a test to determine the performance of the turbine, said test must be arranged for and carried out at the expense of the purchaser. The expenses of a representative of the turbine maker, who must be present, to be included. If the tests show conclusively that the turbine has failed, then all the expenses are automatically transferred to the turbine maker, and he is to be allowed, say, two months to remedy the faults of his apparatus before rejection.

If a test on sight is impossible, the maker can demand that the machine be returned to the works, where a witness test can be made in the presence of the purchaser's representative, the purchaser paying all expenses, including freight, if the machine on test is not at fault, and vice versa, as above.

Neglecting the few instances where both ends of the machine fail, there should be no such thing as dividing the expenses. The machine is right or wrong, and the responsible party should pay all. Cases are on record where a hard and fast rule of this kind would have eliminated years (not months) of controversy over the equitable division of expenses. If the respective parties cannot come to terms, then they should agree to take the decision of an arbitrator mutually agreed upon. As soon as any controversy arises his services should be sought immediately, and not as at present (when this course has been adopted) after months of expensive haggling, with the resulting hard feeling that this invariably creates.

If the customer disputes the performance of the whole outfit, it rests with him to conduct the necessary tests at his own expense, with the same adjustment of costs as above, the makers' engineers to be invited to all such tests.

In all cases of trouble, the customer must first of all see to it that he notifies the right party, i.e., the master contractor. If the turbine breaks down, and the unit is bought from a pump maker, it is primarily the duty of the pump maker to apply the remedy. All dealings with the customer must be through him. Again, if a machine is bought F.O.B. factory from a reputable concern, and trouble is experienced after erection and the services of an expert are requested, the request should be sent by a responsible member of the purchaser's firm, and be considered in the light of a formal order covering said expert's expenses. If the trouble is due to defects in the apparatus, the manufacturer cannot send in a bill and expect any repeat orders.

One of the hardest propositions the manufacturer is confronted with today is to collect for expenses when the trouble has been entirely due to the engineer's absolute neglect of the instruction book furnished with the machine, or other cause for which the manufacturer should in no way be held responsible. If all makers could see their way to adopt a policy of this kind, requests for men by irresponsible under-engineers would rapidly decrease. The fact is that if the engineer knows at the outset that if the trouble is caused by his own negligence and the expense is going to be charged against him, he is naturally going to make sure of his ground before he risks the displeasure of his superiors by showing his incompetence to adjust the machine, or runs up unnecessary bills in his department.

In like manner the subcontractor must expect a formal order from the master contractor for any expert services.

In conclusion, this is not a matter that concerns only the manufacturer from a financial standpoint. It concerns the purchaser, inasmuch as the selling price of the apparatus will be reduced. It also concerns the manufacturer from the standpoint that any advance along the lines suggested cannot have any other effect than to eliminate unpleasant experiences with the customer and thereby increase the popularity of the turbine-driven unit.

The Second Industrial Safety Congress of New York State will be held at Syracuse, N. Y., from December 3 to 6, under the auspices of the State Industrial Commission. Some of the topics to be considered are Safety from an Economic Standpoint as Well as a Humanitarian Proposition, What Part Does Labor Play in the Safety Movement? Disciplining Careless Workmen—How the Employer Feels About It and How the Employee Feels, and Safety Committees, Their Scope and Benefit. The headquarters of the congress will be at the Hotel Onondaga.

Suggestions addressed to owners and managers of power plants for the economical use of coal have been prepared by the Committee on Coal Conservation of the Chamber of Commerce of the United States, which is working in conjunction with the Council of National Defense. The cost of coal for the generation of power, the committee points out, has in many instances not had the same consideration as other costs because coal has been cheap and abundant, so that cheap coal and cheap labor sometimes made it apparently economical in dollars and cents to install and operate an inefficient plant. Coal and labor are now expensive and conditions make it imperative for every owner or manager of a power plant to examine into the cost of the power his establishment uses, the economy with which it is generated and applied and the increase in efficiency that is possible.

Most users of coal can join in promoting efficiency of coal. Railways have made real progress in firing locomotives; they can often go farther. Gas workers can generally effect further saving by using careful technical direction. Manufacturing plants of every degree can show great results in the aggregate.

The Bureau of Mines, on behalf of the Federal Government, has gathered a great deal of information about the use of coal and has expert advice to give regarding means of economy. Several publications, in which the Bureau of Mines has embodied the results of its experiments and made practcal suggestions based upon expert observations and conclusions of its staff and other engineers, are now available and a list can be obtained by application to Director Van H. Manning.

RECENT DEVELOPMENTS IN BALANCING APPARATUS

By N. W. AKIMOFF, PHILADELPHIA, PA.

Member of the Society

Improvements have been made by the author upon the balancing machine described by him in a paper presented before the Society in 1916. They are based mainly on a revision of his former method for securing static balance in a body used as a step in the process of determining its dynamic balance. Two formulae are given to show mathematically the lack of precision in ordinary methods for obtaining such static balance.

The author uses a clamp attached to the body to be balanced, whereby a centrifugal force is introduced when the body is rotated, for the purpose of neutralizing the static or dynamic unbalance of the body. By suitably constraining the motion of the rotating body, either the static or dynamic unbalance, or the combination of both, may be accurately measured through the adjustment of the clamp.

SINCE my paper was presented on the subject of Dynamic Balance,[1] certain improvements have been made in the machine there described; and an entirely new machine based on new methods of balancing has been developed.

The principle of the original machine is indicated in Fig. 1, which shows a lathe bed which takes the form of a beam hinged at one end and supported by a spring at the other. The body to be tested must first be brought into static balance, after which it is rotated in bearings supported by the beam. If the body is dynamically unbalanced its rotation will cause the beam to vibrate in a vertical plane with a period of oscillation equal to the period of rotation of the body.

Suspended from the beam is a second body in the form of a so-called squirrel cage consisting of two circular disks carrying an even number of rods so arranged as to slide in holes in the disks. The cage rotates in unison with the body to be tested and a state of unbalance in this body introduces a centrifugal couple which is neutralized by displacing the rods in the cage until an equal compensating couple has been introduced. The distances that the rods are displaced serve as a measurement of the amount of unbalance to be provided for and counterbalanced in the piece under test.

The improvements upon this original machine, referred to above, are as follows:

a The substitution for the cage of a two-point element consisting of two disks, *A* and *B*, each with a pin projecting from its face, as shown in Fig. 2. The disk *A* is fixed to its shaft and the disk *B* is arranged to slide on the shaft through the use of a feather key *f*. It is clear that when the two disks are in contact they will balance each other; but when separated they will introduce a certain centrifugal couple according to the weight of the pins and the distance between the disks, which latter can be varied while the apparatus is in motion.

b A planetary arrangement by which the relative angular position of the body and the disks (or cage) can be varied while the machine is in operation.

c The application of a principle whereby the disks (or cage) may be arranged to answer the problem of static balance as well as dynamic balance.

The new methods which have been developed and applied in a new type of machine for combination static and dynamic balancing will be referred to later.

STATIC BALANCE

As a result of a great deal of study of the problem of static balance, I have been forced to admit, in common with many other engineers, that too much has been taken for granted in relation to this subject. Static balance is not a trifling problem to be solved easily by placing a rotating body on parallel ways or rollers, as has commonly been supposed. While it is true that static balance can be found without much trouble in the case of bodies of light weight or where the operating speeds are comparatively slow, there are other cases which are much more difficult. For example, consider a gyroscope wheel whose weight is about 50 lb. or so, running at, say, 10,000 r.p.m.; or a turbo-rotor whose weight is 10,000 lb. and whose speed is 3600 r.p.m. Neither of these extreme cases can possibly be handled with any degree of success by placing the bodies on ways; and yet, unless static balance is perfect, no dynamic balancing machine can be expected to give reliable results.

STATIC BALANCE BY MEANS OF PARALLEL WAYS

It may be well to point out that in balancing by the aid of parallel ways there is a limit to the load which can be safely borne by the journals in contact with the ways. A safe load for each journal appears to be 750 lb. per inch of width, per inch diameter of journal.[1] For instance, if the ways are $1\frac{1}{2}$ in. wide and the journal diameter is 10 in., then each side will carry almost 12,000 lb. without any danger of forming permanent flat spots.

It would be of interest if one could estimate the sluggishness of action of a body on the ways under different conditions. The older theories of rolling friction, as proposed by Coulomb, Morin and Dupuit, do not seem to lead to very reliable results. Résal's formula[2] is probably much more reliable and is here reproduced in simplified form (steel on steel):

$$f = 0.056\sqrt{1/(1 + 79/D)}$$

where *f* is the length of the flat contact of shaft with the way and *D* is the diameter of shaft, both in inches. It appears that

For presentation at the Annual Meeting, December 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, 29 West 39th Street, New York. All papers are subject to revision.

[1] According to the writer's remembrance, this figure was first given him by the engineers of the Standard Roller Bearing Co. many years ago, and has since been revised by him in connection with other practical data which he was able to gather from different sources.

[2] Résal, Traité de Mécanique Générale, T. 11, p. 6.

the weight does not enter into the formula, and in general [illegible] should not be considered as extending to extreme [illegible]. It expresses the average run of things at the [illegible] standard practice.

The diagram in Fig. 3 has been roughly plotted to illustrate the probable magnitude of *residual unbalance* which *may* [illegible] a body that has been brought into apparent balance by [illegible] ways. The chart is based on Kesal's formula, and, as it is intended simply to illustrate the meaning of the formula, values have been exaggerated by plotting shafts of small diameter against weights altogether inconsistent there-

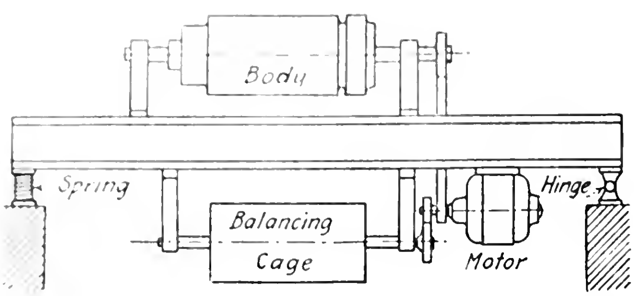

FIG. 1 SQUIRREL-CAGE TYPE OF DYNAMIC BALANCING MACHINE

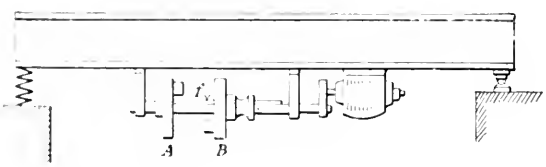

FIG. 2 TWO-POINT BALANCING ELEMENT

with. The chart is easily read. for instance, if a rotor weighs 4000 lb. and diameter of its shaft is 6 in., then the residual unbalance may be as great as 480 ounce-inches, or say, 2½ lb. on a 12-in. radius. It is useless to put a body statically unbalanced to such an extent (or even to 50 per cent of this) on any dynamic balancing machine. Satisfactory results cannot possibly be derived from such tests. An actual case of residual unbalance, typical of many others, is of a shaft having a diameter of $2\frac{3}{32}$ in., a weight of 66 lb. and a residual unbalance of 0.844 ounce-inches. The width of the balancing ways was $\frac{5}{16}$ in. (cast iron chilled and ground).

Considering the phenomenon of rolling friction from the standpoint of higher theories of elasticity (Hertz), the following tentative formula was derived for residual unbalance:

$$M = 0.0004648\, P \sqrt{PD}$$

where M is the residual moment in ounce-inches, P the weight per unit of contact length (that is, per inch of combined width of ways), and D the diameter of shaft in inches (steel on steel). The constant may be considered to be rather tentative, but with the advent of a machine capable of establishing perfect static balance it will not take long to find [illegible] values for it.

[illegible] formula, if an armature weighed 12,000 lb. [illegible] shaft diameter of 8 in., the sluggishness or residual [illegible] ways 1 in. wide, would be:

$$M = 0.0004648 \times 6000 \sqrt{6000 \times 8} = 614 \text{ oz-in.}$$

[illegible] on a 12-in. radius. At 3600 r.p.m. the centrifugal force due to such residual unbalance would be more than 14,000 lb.

USE OF CENTRIFUGAL FORCE IN BALANCING

As previously stated, my earlier machine for dynamic balancing was based on the introduction of *centrifugal couples,* created by the operator to offset the effect of the disturbing centrifugal couple, constituting unbalance in the rotating body. Likewise, a machine for static balancing can be based on the same principle, but long study of the subject has led me to the conclusion that the whole problem of balance, static and dynamic, can be reduced to the principle of a single *centrifugal force* acting on a properly constrained body. Such centrifugal force can be created by the operator, within a rotating body, by such means as, for instance, the clamps of which two designs are here shown (Figs. 4 and 5). As will be explained, such clamps may be used to offset the effect of static or dynamic unbalance in a rotating body, as the case may be, and to record the extent of such unbalance. They should be carefully made and so calibrated that the centrifugal force may be given as a function of some linear dimension, read directly or measured by an accurate scale. The first clamp is easier to make and check for accuracy; while the second design is much handier for quick adjustment on the shaft of a rotating body.

MEANS FOR SECURING STATIC BALANCE

In order to register the effect of static unbalance of a body, or the correction introduced by means of such a clamp as described, the body must be placed in such a condition that its oscillations are emphasized or magnified to an extent that will be visible to the eye; otherwise its unbalance, even if considerable, will not be noticeable and will only result in

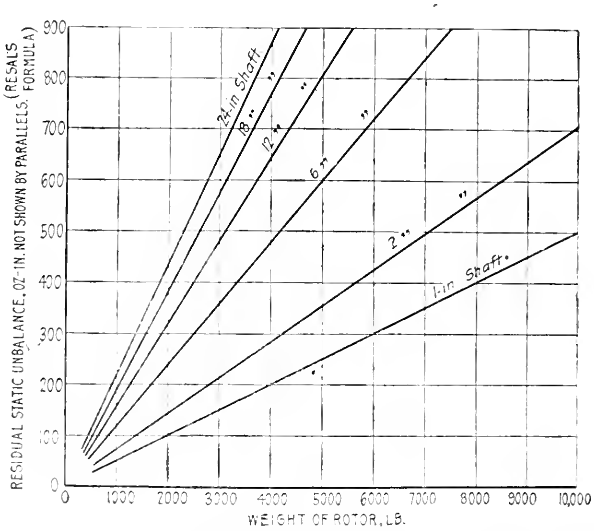

FIG. 3 PROBABLE RESIDUAL UNBALANCE OF BODIES BALANCED ON TESTING WAYS

increased pressure on the bearings. Thus, in a badly unbalanced automobile engine, it is most often possible to pick out a range of speeds where the engine will appear to work smoothly; and many an electric motor with badly unbalanced rotor will apparently run well, simply because its speed may be far away from that which would insure synchronism of the rotation with the oscillation of bearing supports.

Now, suppose we have a frame, suspended as shown in Fig. 9, and capable of a certain period of swinging oscillation. If the body, statically unbalanced, is operated at a speed corresponding to the period of oscillation, the oscilla-

tions of the frame will become violent, and can be readily registered by any suitable dial-gage indicator. Here the body is imposing its own period on the frame, which thus performs what are known as forced vibrations of the same period. Our task is then to adjust the speed of the body so that the period of such forced oscillation will be equal to that of the natural oscillation of the frame and body (at rest).

enough to see that a clamp k can always be so adjusted, both angularly and as regards its off center position, so as to nullify the oscillations of the frame, thereby solving the problem of static balance. No matter how heavy the body, it is always possible to place it into most minute balance by this method, where ordinary parallels would be altogether inoperative.

In Lord Rayleigh's remarkable book[1] a most lucid explanation is given of this phenomenon of "step" or synchronism.

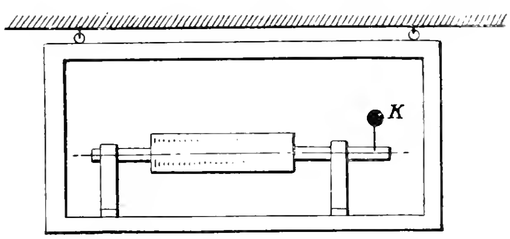

Fig. 9. Body Supported in Swinging Frame for Securing Static Balance

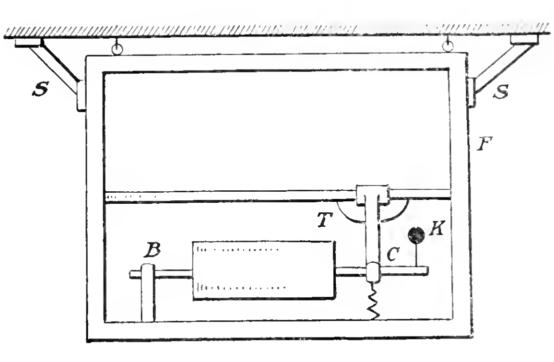

Fig. 10 Body with One Floating Bearing, Supported in Rigid Frame for Securing Dynamic Balance

Lord Kelvin's well-known device called a "vibrometer" is likewise based on this very principle. Of course, it is easy

Dynamic Balance

As regards dynamic balance, due, in a statically balanced body, only to the presence of a centrifugal couple, the following remarks can be made: In the first place the "theory" that this centrifugal couple is due to the fact that the centers of gravity of both halves of the body, cut through its center of gravity, do not lie on the axis of rotation, is radically wrong. Take for instance a skeleton body shown in Fig. 6. Its center of gravity is exactly on the axis of rotation, as also are the individual centers of gravity of each half, to the right and to the left from A to B. Yet such a body would be manifestly out of balance (dynamically). Inversely, a body would readily be imagined to be both in static and dynamic balance, although each of its *halves* were statically out of balance. The only correct way to characterize dynamic balance is to say that the *products of inertia*, containing the axis of rotation, vanish[2]; or, to put it practically, that there is no centrifugal couple in any axial plane.

In the next place, if we constrain (pivot) one end of a rotating body (statically balanced but dynamically out of balance) while the other end is arranged to float in a bearing supported by springs so that it may move, say, in a horizontal plane, Fig. 7, then the oscillations of the body will be angular, as from A to B. Under these conditions the observer will be unable to tell whether the vibrations are due to a *force* (centrifugal) acting somewhere on the body or to a centrifugal couple, unless he knows beforehand that the body is in perfect static balance, under which conditions the vibratory effect can be due only to dynamic unbalance. This being the case, in

[1] Theory of Sound.

[2] Slocum, Theory and Practice of Mechanics, p. 297.

[illegible] of the reaction of the constrained end, it is perfectly possible to balance the effect of a centrifugal couple by means of a centrifugal force. Thus, in Fig. 8, if it is assumed that the dynamic unbalance is due to the couple $a\ b$, it will always be possible to select a centrifugal force c, such that it will quiet the vibrating body, and because of its known distance from the bearing B, establish the exact value, sign and angular position of the disturbing centrifugal couple $a\ b$.

It is thus clearly seen that it is possible to utilize a centrifugal force to good advantage in finding both static and dynamic unbalance of bodies; and combining the principles illustrated in Figs. 7 and 9, we have a combination static and dynamic balancing machine, of which the scheme is as follows:

DESCRIPTION OF IMPROVED BALANCING MACHINE

A frame F, Fig 10, supports the bearings B and C, which carry the body. The frame has a swinging period of its own. The bearing C may either be locked, so that it acts exactly like the rigid bearing B; or else it may be allowed to float in

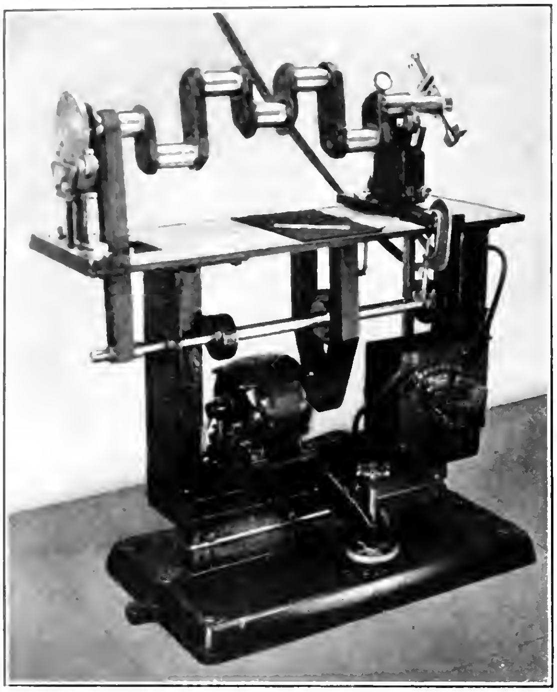

Fig. 11 Combined Static and Dynamic Balancing Machine

a vertical plane, bringing into play certain resistances (springs) opposing its deflection from the neutral (vertical) position. The correcting centrifugal force is indicated by k.

Such a system is known in dynamics as a *system with two degrees of freedom*, in general being capable of two kinds of motion: swinging of the frame, the bearing C being maintained rigid; and swinging of the bearing C, the frame F being maintained rigid by such means as brackets S; while the most general motion consists of a combination of these two motions.

The operation of such a combination machine is very clear. In order to secure static balance we lock the bearing C and unlock the frame supports S. Then, by properly adjusting the magnitude and direction of k we can reduce to zero the bodily oscillations of the frame F, thus establishing the exact value and sign of static unbalance in ounce-inch units. As soon as this has been corrected, we lock the frame F and unlock the bearings C, when the same centrifugal force k, created by a suitable adjustment of the clamp as explained above, can be made to correct the body for dynamic unbalance, as illustrated in Fig. 7. The advantage of basing the results on the centrifugal force instead of on a centrifugal couple is manifest, the former being a *fundamental*, and the latter a *derived*, unit, so that the former is capable of much greater accuracy in adjustment and of more direct application than the latter.

Fig. 11 illustrates a balancing machine built in accordance with the scheme of Fig. 10. The yielding support, clearly shown on the right, has means for easy adjustment of its period, as likewise has the frame itself. The motor is of $\frac{1}{3}$ hp. capacity and operates the body, through a countershaft, by a rubber belt. The balancing clamp is seen on the extreme right of the crankshaft. The oscillations are read by means of ordinary Starrett dial gages, graduated in thousandths of an inch. The precision which can be secured on such a machine is almost uncanny; it enables one to see the sluggishness of the method of balancing on ways and therefore the absolute lack of precision of dynamic balance that might be based on such results. A well-designed clamp is very easily handled and its correct position can be established in a few minutes. Its indications are capable of tabular interpretation, so that the operator has merely to carry out the simple instructions, worked out beforehand. Of course, it is clear that such a machine can be built for any size of body, or for any speed that may be desired.

Two minerals not heretofore known to science have been discovered at Crestmore, Cal., according to a bulletin issued yesterday by Prof. Arthur Eakle, department of geology, University of California. Professor Eakle has christened the discoveries respectively "crestmoreite" and "riversideite." The first is described as a new hydrous basic orthosilicate, containing small amounts of other oxides in place of silica. The latter is a hydrous lime sulphate.—*Minneapolis Morning Tribune,* October 31, 1917, p. 1.

A report on the deterioration in the heating value of coal during storage, covering a five-year period, has just been issued by the Bureau of Mines, Department of the Interior, as Bulletin 136. The tests show that the amount of deterioration has commonly been overestimated. Except for the subbituminous Wyoming coal, no loss was observed in outdoor weathering greater than 1.2 per cent in the first year, or 2.1 per cent in two years. The bulletin, of which the authors are Horace C. Porter and F. K. Ovitz, may be obtained free of charge by addressing the director of the Bureau of Mines, Washington.

Roughly, two pounds of seasoned wood have a fuel value equal to one pound of coal, according to experts of the United States Forest Service. Different kinds of wood have different fuel values, and in general the greater the dry weight of a nonresinous wood the more heat it will give out when burned. For such species as hickory, oak, beech, birch, hard maple, ash, locust, longleaf pine or cherry, which have comparatively high fuel values, one cord, weighing about 4000 lb., is required to equal one ton of coal; it takes a cord and a half (a total weight of 4500 lb.) of shortleaf pine, hemlock, red gum, Douglas fir, sycamore or soft maple, which weighs about 3000 lb. a cord, to equal a ton of coal; while of cedar, redwood, poplar, catalpa, Norway pine, cypress, basswood, spruce and white pine, two cords, weighing about 2000 lb. each, or 4000 lb., are required.—*Power,* November 13, 1917, p. 657.

EXPENSES AND COSTS

By H. L. GANTT, NEW YORK, N. Y.

Member of the Society

In determining the cost of a manufactured article, should we include all the expense incurred while that article is being manufactured, or should we include only those expenses which contribute to its production?

It does not require any knowledge of cost accounting, bookkeeping, or other office art to enable the practical man to say that costs should include only those expenses needed to produce the article in question, and that those people who insist on including in their costs expenses which do not contribute to the production of the article are simply trying to recover from the public through a higher selling price the expenses which they incur through inefficiency and waste.

All cost figures may be divided into three parts:

a Expense for material
b Expense for labor
c Overhead expense, or "burden."

There is no great difficulty about getting the expense for material and the expense for labor, and most concerns get these elements quite accurately, but there is a great variety of opinion as to what the "burden" charge on any particular work should be. This overhead or "burden" may be divided into two parts:

a That which is incurred through simple ownership or rental of the plant and keeping it ready for operation
b That which is incurred by operating the plant, exclusive of direct labor and material.

Analyzing further the meaning of the term "burden," we see that the first part is made up of ownership or rental of a number of machines or work benches, properly housed. The second part consists of the expense of operating the various machines, which consists of such items as power, oil, waste, repairs, etc.

Inasmuch as the rental which we should pay for the plant is made up of the rental of the individual machines and work spaces, we must be able to determine the proper rental for each of these in order to form an intelligent idea of the proper rental for the whole plant. In the same way we can determine the amount of supervision, power, oil, and waste needed to run these machines individually.

Working along these lines, we are able to determine for each machine in the factory both an idle- and an operating-expense rate.

Any article manufactured on a machine should undoubtedly bear the operating-expense rate for the time during which the machine was operated on it.

The expense of maintaining the machine in idleness during the time it was not operated cannot legitimately be charged to the work done while it was operated, and should be put into another account.

We thus see that in every plant there are to be considered two kinds of burden:

a That which produces goods and which can legitimately be charged to the cost of those goods, and
b That which produces nothing, and must be put into some other account.

For presentation at the Annual Meeting, December 1917, of The American Society of Mechanical Engineers, 29 West 39th Street, New York. All papers are subject to revision.

In the past it has been too much the fashion to put these two kinds into one account and make the product bear both. This has led to so much confusion, and is so evidently wrong, that it is not worth discussion.

On the other hand, a careful consideration of the expense incurred while the plant is idle leads to very fruitful results: first, through an attempt to find out why the plant is idle, and then through an attempt to eliminate the causes of idleness, which are lack of work, lack of help, lack of material, repairs, etc.

Without going into the details of those subjects, it may be readily appreciated what advantages will be derived from a careful study of each of these causes.

This general view of the cost question leads to a further simplification of the problem which is worthy of careful consideration.

First, the expense of owning and maintaining a certain machine in idleness properly equipped for efficient operation should be substantially the same in any part of the country where the machine could be bought at substantially the same price.

Second, the amount of power, oil, waste, and repairs, and even supervision, of a certain machine should be substantially the same in any part of the country, if it were engaged upon substantially the same kind of work.

Following these lines of thought, we readily see that a standardization of cost methods and of costs is possible, which was unsuspected a few years ago.

While the writer and those with whom he has been associated have done quite a good deal of work on these lines, and while the results have been satisfactory to a degree that was entirely unanticipated, he does not yet feel that the matter has been developed to such a degree as to warrant detailed publication. The fact, however, that the Federal Government has placed so many contracts on a "cost plus" basis, leads him to set forth these ideas, which are the only ones which seem to him to give promise of avoiding an almost intolerable situation resulting from a complication of interests which is bound to arise in the near future.

It seems to the writer that much of the confusion on the subject of costs in the past has been due to a misconception of the subject. The intimate relation between production and costs has not been sufficiently recognized, for the accountant has looked upon costs as a bookkeeping proposition, whereas, in truth, costs are much more closely connected with engineering and production than with the subjects of bookkeeping and accounting.

If the engineer will recognize this fact and insist that money spent without any corresponding production must be kept separate from that which was productive, either directly or indirectly, many of the apparent contradictions with which we are so frequently faced will be eliminated.

As soon as we establish these methods, the following question is immediately put to us by the accountant and financier, "What are we going to do with this expense of idleness?" they having never before realized that it cost something to be idle.

My frank answer to that is that I do not know. Moreover, I don't care, provided they do not charge it to me in the prod-

[illegible] I may exempt them. My recommendation, however, [illegible] how they can eliminate such expense [illegible] methods.

I am perfectly aware that it is extremely difficult to eliminate [illegible] of such expense, but I am also aware of the fact that it is extremely easy to eliminate a large proportion of it. The solution of this problem is one of the economic questions which the war will shortly force to our attention, and I insist that it is primarily a question to be solved by engineers rather than by financiers.

APPARATUS FOR COOLING, DRYING AND PURIFYING AIR

By W. J. BALDWIN, NEW YORK, N. Y.

Member of the Society

This paper describes an apparatus for purifying air and regulating its temperature and humidity by mechanical means. In principle it consists of the use of a cold spray for the purification process, after which the excess moisture, together with particles of dust, excess CO_2, etc., are separated from the air by centrifugal action. In one of its original forms the device was applied to the porthole of a ship for the purpose of drawing into the cabin large quantities of air but excluding rain or spray. It has also been used to remove CO_2 from vitiated air, as in the compartments of a submarine, and for removing particles of dust from the gases of combustion in a chimney.

THE necessity for removing dust and other impurities from the air needs no amplification from me, as we all recognize the advantages of pure air and nearly all strive in every way to obtain it.

The ordinary meaning of the term pure air, however, should be amplified, and when it appears in a contract it should mean more than that the air should not be fouled by the human breath and by exhalations from the human body. The engineer must not be content when making an examination within an enclosed structure simply to report that the air is maintained at some common standard of purity of contamination, expressed by the number of times the CO_2 within the room is in excess of the standard, good or bad, found to exist outside the enclosure. Such a standard gives only an approximate idea of the condition of the air within the enclosed space, and it is the roughest approximation under the common acceptance of the term.

Presumably there is no pure air near the surface of the ground, nor in the atmosphere of cities. The best we have exists at the tops of mountains, or on the ocean, but even this we are unable to standardize.

Air with about two parts of CO_2 in 10,000 is considered good, no matter where we find it; but in cities where much coal is burned the proportion is higher, and may rise to as high as 10 parts of CO_2 in 10,000. An increase from 2 to 4 parts in 10,000 for enclosed spaces above the outside conditions has been considered good, even for schools and hospitals, and very good for workshops.

These conditions, however, do not comprise the whole problem. Further effort should be directed toward drying air by some simple mechanical process. In attempting to free air from an excess of humidity, which is often as much of an impurity as are the other forms of contamination, I have the following data to offer:

About two years ago I worked to perfect an apparatus[1] that could be put in the porthole or the dead light of a ship and would exclude the rain or spray, while freely admitting large quantities of air to the cabin of the ship, without admitting the water. This led to freeing the air of an excess of humidity.

The experiments conducted with the preliminary apparatus for excluding rain or spray while freely admitting the air as in the case of a ship rolling heavily at sea, suggested the possibility of removing the excess of humidity in the air, particularly with a view to admitting air to the radio room of a ship, and not only exclude the rain and the spray but also regulating the humidity, so as to keep the air at *some common standard of saturation* as far as humidity was concerned. The purpose was to overcome a difficulty with the attuning apparatus of the receiving and sending instruments, either at sea or in the higher atmosphere.

This led to the design of an apparatus for a radio room on the lines already set forth, that would admit air not only separated from rain, salt spray and spume, but that would also condition or regulate the humidity within the room by keeping it at a common standard of humidity, regardless of the outside changes.

Cold water in the spray form will do this provided the spray can be gotten rid of after it has combined with the excess of humidity (steam in the air) and then separated from the air by some practicable form of apparatus that is simple, and that occupies small space.

While a shower of rain will clear the atmosphere, the elements of nature have all outdoors in which to set up the apparatus for such a result. The cabin of a ship or a radio cabinet is infinitely small in comparison with all outdoors, yet a similar result can be achieved in a space as small as a cabin or radio cabinet.

To accomplish this I used a cold-water spray apparatus similar to one I had designed two years earlier for the purpose of precipitating the CO_2 when found in great excess in a confined space, as in the hold of a submarine, when forced to stay a long time under water.

In this machine a spray of potash water was used in connection with a mechanical dust precipitator for the purpose of seizing on the carbonic acid in the air and throwing it down so as to eliminate the CO_2 at the dust and water discharge of the apparatus.

It was proposed to put the apparatus in a bulkhead; the discharge side of the apparatus coming into the air of the

[1] A description of this apparatus, with illustrations, appeared in the [illegible] of the American Society of Heating and Ventilating Engineers, [illegible] 1917.

For presentation at the Annual Meeting, December, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, 29 West 39th Street, New York. All papers are subject to revision.

living quarters, the air freed of its CO_2 being forced backward again into the chamber of greatest vitiation, thus forming a cycle.

In the general experiments it was found that a prepared spray of chemical liquid or even cold water not only seized on the dust but on other gases in the air, with which the chemical in the spray would combine, and that a pure-water spray turned into the apparatus would keep the humidity of the air constant by suitable regulation of the temperature of the water spray. In a room at 90 deg. fahr. and a humidity of almost 90 per cent we could drop the humidity to 45 per cent by reducing the temperature of the spray to 70 deg. fahr.

A simple form of the apparatus arranged for cooling a room is shown in Fig. 1. The apparatus from the inlet to the

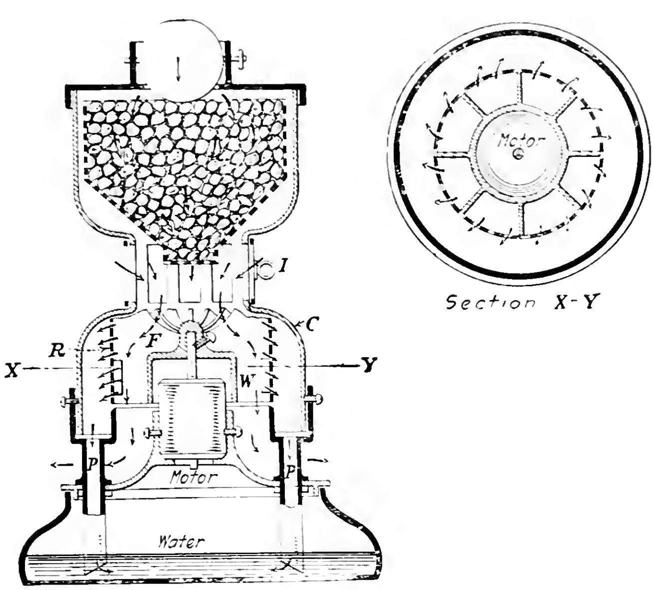

Fig. 1 Apparatus for Purifying and Cooling the Air of a Room and Illustrating Also the Principle Used in Various Other Forms of the Device

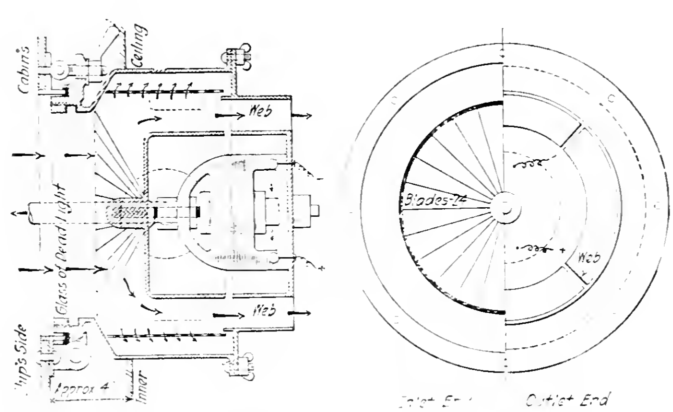

Fig. 2 Apparatus Attached to Porthole of Ship for Admitting Air and Excluding Rain or Spray

line X-Y is an ordinary fan or blower F, and the downward extensions of the fan blades or wings W are necessary to accelerate the rotary motion of the air.

The rotor R is a rotating hoop of permeable metal, against the inner side of which the air is thrown with all its impurities. If the heavy particles in the air, such as dust, mud or particles of water, strike into the perforations of the hoop, they pass through into a quiet space formed by the outer case C. Or, if they strike on the solid part of the hoop, they are rubbed through the nearest holes by the forward movement of the air. They then pass into the quiet space C, drop down within it, and escape by the pipe or pipes P into the tank.

The air does not escape with the heavy particles, as might appear at first, for the lower ends of the pipe legs are sealed by the water in the tank. The tank may be of any shape, or there may be no tank, the separated particles going to a waste pipe.

The greater the velocity of the rotor R the more efficient is the apparatus. A speed of 5000 ft. per min. is very practicable, but 10,000 is not excessive, either from the point of bursting or for any other reason.

The fan gives the same static pressure as any other centrifugal blower of equal diameter and speed and requires only equal power for equal work, and the power required for separation and friction is considerably under 25 per cent of the blower power required to move the air.

The device as described above illustrates the principle of the various types of apparatus, whether used for taking the

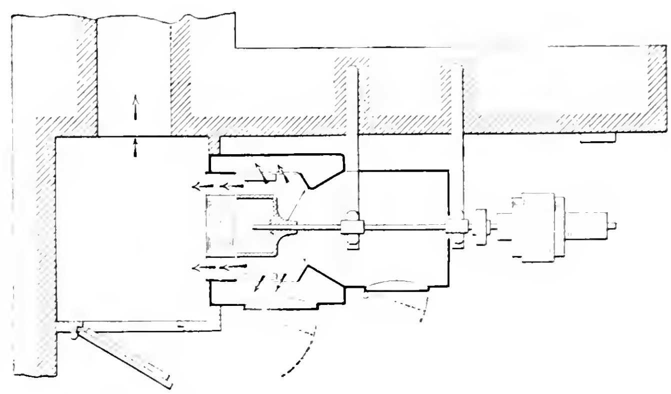

Fig. 3 Application of Apparatus to Base of Chimney for Removing Particles of Dust from Gases of Combustion

dust from the air, the CO_2 from a chimney or an enclosed space, the excess of humidity from the air, throwing down fog, cooling and moving air, etc. It will be noted that the ice in the upper tank serves both as a cooling medium and for the supply of cold water, broken into spray by the rapid motion of the fan, for the purification of the air.

In Fig. 2 is shown a type of the apparatus as developed for use in the porthole of a ship, and in Fig. 3 a horizontal design for the removal of dust particles from the gases of combustion in a chimney.

France and England freely acknowledge that they greatly decreased their efficiency by sending their scientific men to the trenches. Although they have since withdrawn most of those still alive and are now using them in special service, the dearth of technically trained men has been and is severely felt.

The American Association for the Advancement of Science and many national scientific societies affiliated with it will hold its seventieth meeting in Pittsburgh, Penn., from December 28, 1917, to January 2, 1918, under the auspices of the University of Pittsburgh, the Carnegie Institute, the Carnegie Technical Schools and other institutions.

REVISION OF BOILER CODE

THE Council of the Society directed that a hearing be conducted in accordance with the recommendation in the Boiler Code that a meeting at which all interested parties may be heard be held at least once in two years to make such revisions as may be found desirable in the Code and to modify the Code as the state of the art advances. The first of these meetings was held at the Society's headquarters in New York, December 8 and 9, 1916.

The Council also directed that the proposed revisions in the Boiler Code be published in THE JOURNAL with the request that they be fully and freely discussed, so as to make it possible for any one to suggest changes before the Rules are brought to the final form and presented to the Council for approval. Discussions should be mailed to Mr. C. W. Obert, Secretary of the Boiler Code Committee, 29 West 39th Street, New York, N. Y., and they will be presented and acted on by the Boiler Code Committee.

Revisions formulated by the Committee earlier in the year were published in the June 1917 issue of THE JOURNAL, pages 517 to 522, and in the August 1917 issue, page 705. The revisions which follow are divided into two parts, namely: Part I, Modifications of the Proposed Revisions published in the June and August issues (the modifications being made to conform with recommendations submitted to the Committee by those discussing the proposed revisions), and Part II, Aditional Revisions proposed by the Boiler Code Committee.

PART I

Modifications of the Proposed Revisions Published in the June and August Issues of THE JOURNAL

PAGE 50

PAR. 200. CHANGE PAR. 200 TO MAKE IT READ AS FOLLOWS:

200 *Staybolts.* The ends of screwed staybolts shall be riveted over or upset by equivalent process. Staybolts must be hollow or the outside ends of solid staybolts, 8 in. and less in length, shall be drilled with a hole at least 3-16 in. diameter to a depth extending at least ½ in. beyond the inside of the plates, except on boilers having a grate area not exceeding 15 sq. ft., or the equivalent in gas or oil fired boilers, where the drilling of staybolts is optional. Solid staybolts over 8 in. long, and flexible staybolts of either the jointed or ball and socket type need not be drilled.

PAR. 201. ADD TO PAR. 201 THE FOLLOWING:

If the outstanding legs of the two members are fastened together so that they act as one member in resisting the bending action produced by the load on the rivets attaching the members to the head of the boiler, and provided that the spacing of these rivets attaching the members to the head is approximately uniform, the members may be computed as a single beam uniformly loaded and supported at the points where the through braces are attached.

PAR. 214. CHANGE PAR. 214 TO MAKE IT READ AS FOLLOWS:

214 *Areas of Segments of Heads to be stayed.* The area of a segment of a head to be stayed shall be the area enclosed by lines drawn 2 in. from the tubes and a distance d from the shell as shown in Figs. 13 and 14. The value of d used shall be the larger of the following values but not less than 3 in.

(1) d = the outer radius of the flange, not exceeding 8 times the thickness of the head

(2) $d = \frac{5 \times t}{\sqrt{P}}$

Where d = unstayed distance from shell in inches
t = thickness of head in sixteenths of an inch
P = maximum allowable working pressure in lb. per sq. in.

PAR. 215. CHANGE PAR. 215 TO MAKE IT READ AS FOLLOWS:

215 When the heads of drums of water tube boilers are 30 in. or less in diameter and the tube plate is stiffened by flanged ribs or gussets, no stays need be used if a hydrostatic test to destruction of a boiler or unit section built in accordance with the construction, shows that the factor of safety is at least five.

PAGE 54

TABLE 4. SEVERAL REVISIONS HAVE BEEN MADE IN TABLE 4 AND IT WILL NOW READ AS FOLLOWS:

TABLE 4 MAXIMUM ALLOWABLE STRESSES FOR STAYS AND STAYBOLTS

Description of Stays	Stresses, lb. per sq. in.	
	For lengths between supports not exceeding 120 diameters	For lengths between supports exceeding 120 diameters
a Unwelded or flexible stays less than twenty diameters long screwed through plates with ends riveted over	7,500	.....
b Unwelded stays and unwelded portions of welded stays, except as specified in line *a* and line *c*	9,500	8,500
c Steel through stays exceeding 1½ in. diameter	10,400	9,000
d Welded portions of stays	6,000	6,000

PAGE 58

PAR. 231. CHANGE PAR. 231 TO MAKE IT READ AS FOLLOWS:

231 *Maximum Allowable Working Pressure on Truncated Cones.* *a.* Upper combustion chambers of vertical submerged tubular boilers made in the shape of a frustum of a cone, when not over 38 in. diameter at the large end, may be used without stays if computed by the rule for plain cylindrical furnaces (Par. 239) making D in the formula equal to the diameter at the large end, and provided that the longitudinal joint conforms to the requirements of Par. 239.

b. When over 38 in. in diameter at the large end, that portion which is over 30 in. in diameter shall be fully supported by staybolts or gussets to conform to the provisions for staying flat surfaces. In this case the top row of staybolts shall be at a point where the cone top is 30 in. or less in diameter.

In calculating the pressure permissible on the unstayed portion of the cone, the vertical distance between the horizontal planes passing through the centers of the rivets at the cone top, and through the center of the top row of staybolts shall be used as L in Par. 239, and D in that paragraph shall be the inside diameter at the center of the top row of staybolts.

PAGE 61

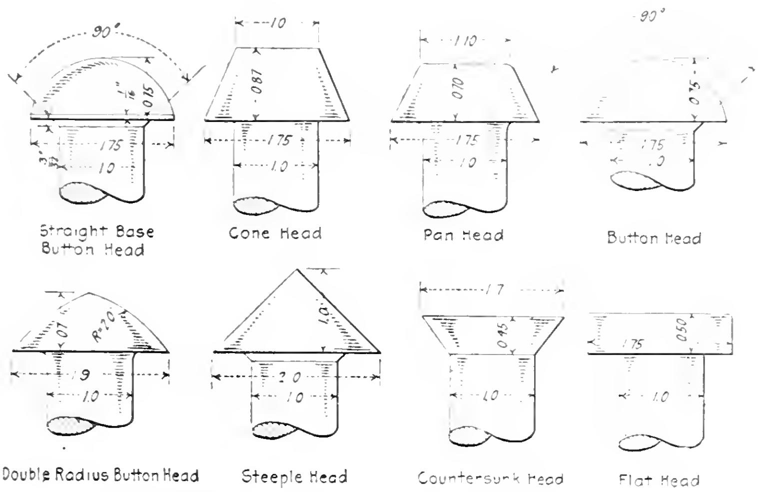
Par. 239. Insert after the formula and just preceding the example in Par. 239, eliminating the present sentence:

Where the furnace has a riveted longitudinal joint, it may be of the lap type for inside diameters not exceeding 36 in. for furnaces 36 in. or less in height or length, and for inside diameters not exceeding 30 in., irrespective of the height or length. Otherwise butt and strap construction shall be used. The efficiency of the joint shall be greater than:

$$\frac{P \times D}{1250 \times T}$$

PAGE 64

Par. 246. As stated in the June issue of The Journal it had been decided to change Par. 246, to Par. 246*a*,



Proportions may be larger or 1/10 smaller than those shown.
Fillet under heads may be used but are not required.

Fig. 17a Acceptable Forms of Rivet Heads

and to add Par. 247, calling it Par. 246*b*. Since the publication of the June issue of The Journal it has been proposed to revise this new Par. 246*b* (formerly Par. 247) to read as follows:

b A cast-iron header when tested to destruction, shall withstand a hydrostatic pressure of at least 1200 lb. per sq. in. and a malleable-iron header, 1500 lb. A hydrostatic test at 400 lb. per sq. in. for cast iron and 500 lb. per sq. in. for malleable iron shall be made on all new headers with tubes attached.

This has been referred to a Sub-Committee of the Boiler Code Committee on Malleable Iron for consideration.

Par. 247. As it was decided to change Par. 247 to Par. 246*b*, a new Par. 247 was proposed and published in the June issue of the Journal. The new paragraph contained two parts, *a* and *b*. It has been decided to omit the first part, *a*, entirely, and to revise the remaining portion slightly, so that Par. 247 will read as follows:

247 Where it is impossible to calculate with a reasonable degree of safety the strength of a boiler structure or any part thereof, a full sized sample shall be built by the manufacturer and tested to destruction in the presence of the Boiler Code Committee or one or more representatives of the Boiler Code Committee appointed to witness such test.

PAGE 65

Par. 253. Change Par. 253 to make it read as follows:

253 *Drilling of Holes.* All rivet holes and staybolt holes and holes in braces and lugs shall be drilled full size or they may be punched not to exceed 1/4 in. less then full diameter for material over 5-16 in. in thickness, and 1/8 in. less than full diameter for material not exceeding 5-16 in. in thickness, and then drilled or reamed to full diameter with plates, butt straps, braces, heads and lugs bolted in position. Tack bolts for seams shall be not over 12 in. apart.

Par. 255. The illustration showing forms of rivet heads that will be acceptable is Fig. 17*a*.

PAGE 68

Par. 268. Change Par. 268 to make it read as follows:

268 *Threaded Openings.* A threaded pipe connection 1 in. in diameter or over shall have not less than the number of threads given in Table 7.

TABLE

If the thickness of the material in the boiler is not sufficient to give such number of threads, the opening shall be reinforced by a pressed steel, cast steel, or bronze composition flange, or plate, so as to provide the required number of threads as shown in Fig. 18a.

When the maximum allowable working pressure exceeds 100 lb. per sq. in., a flanged nozzle shall be used for all threaded pipe openings over 3 in. pipe size.

Par. 269. Change Par. 269 to make it read as follows:

269 *Safety Valve Requirements.* Each boiler shall have two or more safety valves, except a boiler for which one safety valve having a relieving area of 3/4 sq. in. or less is required by the rules.

PAGE 69

Par. 273. Change Par. 273 to make it read as follows:

273 Each safety valve shall be plainly marked by the manufacturer. The markings may be stamped on the body, cast on the body, or stamped, etched, or cast on a plate or plates riveted to the body, and shall contain the following:

a The name or identifying trademark of the manufacturer
b The nominal diameter with the words "Bevel Seat" or "Flat Seat"
c The steam pressure at which it is set to blow
d The lift in inches of the valve disc from its seat, measured at a pressure 3 per cent higher than that at which the valve is set to blow
e The weight of steam discharged in pounds per hour at a pressure 3 per cent higher than that for which the valve is set to blow
f A.S.M.E. Standard.

PAGE 74

Par. 282. Change Par. 282 to make it read as follows:

282 For the purposes of inspection and to insure the valve being free, each safety valve shall have a substantial lifting device by which the valve may be raised from its seat at least 1-16 in. when there is no pressure on the boiler.

PAR. [illegible] ADD TO PAR. [illegible] THE FOLLOWING:

[illegible] safety valve shall be non ferrous [illegible] safety valve shall be fastened [illegible] such a way that there is no [illegible]

[illegible] PAR. [illegible] TO READ AS FOLLOWS:

[illegible] used in safety valves shall not show a [illegible] exceeding 1/32 in. ten minutes after being [illegible] from a cold compression test closing the spring [illegible]. The spring shall be so constructed that the valve [illegible] at 1/10 the diameter of the seat before the coils are closed or before there is other interference.

PAR. 286. CHANGE PAR. 286 TO MAKE IT READ AS FOLLOWS:

286 All flange dimensions shall conform to the American Standard given in Tables 15 and 16 of the Appendix for the pressures therein specified except that the face of the safety valve flange and the nozzle to which it is attached may be flat and without the raised face for pressures up to and including 250 lb. per sq. in. For higher pressures, the raised face shall be used.

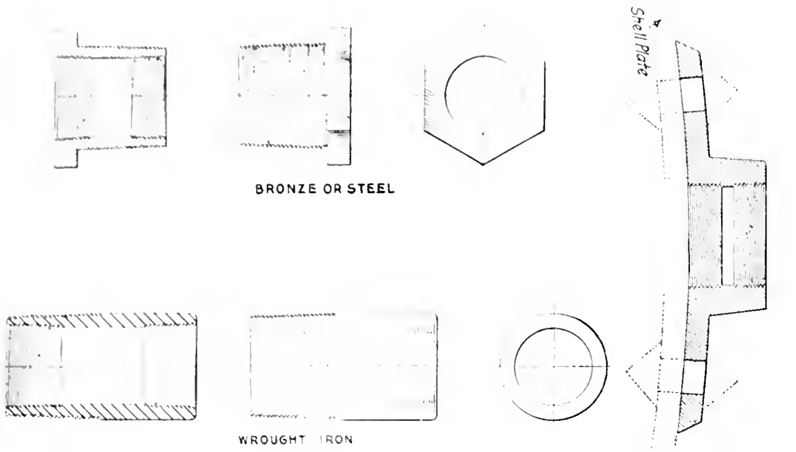


FIG. 18A TYPES OF BOILER FLANGES AND BUSHINGS

PAGE 75

PAR. 291. ADD TO PAR. 291 THE FOLLOWING:

The lowest permissible water level for various classes of boilers shall be the location of the fusible plug as given in Par. 430 of the Appendix.

PAR. 292. A REVISION OF THIS PARAGRAPH WAS PUBLISHED IN THE JUNE ISSUE OF THE JOURNAL BUT IT HAS BEEN FINALLY DECIDED TO CANCEL THIS PROPOSED REVISION AND TO LEAVE PAR. 292 AS IT STANDS IN THE 1914 EDITION OF THE CODE. THIS MATTER HAS BEEN REFERRED TO A SPECIAL SUB-COMMITTEE OF THE BOILER CODE COMMITTEE.

PAGE 76

PAR. 299. CHANGE PAR. 299 TO MAKE IT READ AS FOLLOWS:

299 [illegible] *and Fittings.* Flanged cast iron pipe [illegible] used for boiler parts, for pressures up to and [illegible] lb. per sq. in., shall conform to the American [illegible] in Tables 15 and 16 of the Appendix, [illegible] the face of the flange of a safety valve as [illegible] a safety valve nozzle, may be flat and [illegible] For pressures above 160 lb. per sq. in. steel cast or wrought steel fittings shall be used for boiler parts with exceptions specified in Pars. 9 and 12. An allowable variation of 20 per cent from the flange thickness required by Tables 15 and 16 may be made for steel cast and forged steel fittings, leaving the drilling of bolt holes unchanged. For pressures above 250 lb. per sq. in., the flange thickness and the thickness of the bodies shall be increased to keep within the same deflection limits and to give at least the same factor of safety as the fittings specified in Tables 15 and 16. The flange of a safety valve may have a flat face for pressures up to and including 250 lb. per sq. in., and shall have a raised face at higher pressures; a safety valve nozzle may have a flat face for pressures up to and including 250 lb. per sq. in. and shall have a raised face at higher pressures. Tables 15 and 16 do not apply to flanges on the boiler side of steam nozzles or to flanges left by the manufacturer as part of the boiler, and do not apply to fittings designed as part of the boiler.

PAR. 307. CHANGE PAR. 307 TO MAKE IT READ AS FOLLOWS:

307 *Blow-off Piping.* A surface blow-off shall not exceed $1\frac{1}{2}$ in. pipe size and the internal and external pipes shall form a continuous passage, but with clearance between their ends and arranged so that the removal of either will not disturb the other. A properly designed brass or steel bushing as shown in Fig. 18A or flanged connection, shall be used.

PAGE 77

PAR. 311. CHANGE PAR. 311 TO MAKE IT READ AS FOLLOWS:

311 *a.* On all boilers except those used for traction and portable purposes, when the maximum allowable working pressure exceeds 125 lb. per sq. in., each bottom blow-off pipe shall have two valves, or a valve and a cock, and such valves, or valve and cock, shall be extra heavy, except that on a boiler having multiple blow-off pipes, a single master valve may be placed on the common blow-off pipe from the boiler, in which case only one valve on each individual blow-off is required.

b. All traction and portable boilers shall have one bottom blow-off valve; when the maximum allowable working pressure exceeds 125 lb. per sq. in., the blow-off valve shall be extra heavy.

PAR. 315. ALLOW THE REVISION TO STAND AS IT APPEARS IN THE JUNE JOURNAL AND ADD TO IT THE FOLLOWING:

In Fig. 18*a* is illustrated a standard form of flange to use on boiler shells for passing through piping such as feed, surface, blow-off connections, etc., and which permits of the pipes being screwed in solid from both sides in addition to the reinforcing of the opening in the shells.

PAGE 79

PAR. 325. ALLOW THE REVISION TO STAND AS IT APPEARS IN THE JUNE JOURNAL AND ADD TO IT THE FOLLOWING:

For traction or portable boilers, studs with pipe threads may be used.

PAR. 328. CHANGE PAR. 328 TO MAKE IT READ AS FOLLOWS:

328 A water-tube boiler shall have the firing door or clinker doors of the inward opening type unless such doors are provided with substantial and effective latching or fastening devices to prevent them from being blown open by pressure on the furnace side.

PAGE 82

PAR. 343. ALLOW THE REVISION TO STAND AS IT APPEARS IN

the June issue except that it is now made one paragraph as follows:

343 In a *hot-water* boiler to be used exclusively for heating buildings or hot-water supply, when the diameter does not exceed 60 in. and the grate area does not exceed 10 sq. ft., or equivalent as defined in Pars. 359 and 360, longitudinal lap joints will be allowed. When the grate area exceeds 10 sq. ft., or euivalent as defined in Pars. 359 and 360, and the diameter of the boiler does not exceed 60 in., longitudinal lap joints will be allowed provided the maximum allowable working pressure does not exceed 50 lb. per sq. in.

PAGE 113—APPENDIX

Par. 430. A revision of the first line of Par. 430 was published in the June issue of The Journal. It has now been decided to cancel this revision and let the first line stand as it appears in the 1914 Edition of the Code. In the June Journal a proposed addition to Par. 430 was published, and it has been decided to allow this addition to remain as it appears in The Journal, so that the final form of Par. 430 is the same as in the 1914 Edition of the Code with the addition of clause *v* as follows:

v Fire Engine Boilers are not usually supplied with fusible plugs. Unless special provision is made to keep the water above the firebox crown sheet other than by the natural water level, the lowest permissible water level shall be at least 3 in. above the top of the firebox crown sheet.

Letter to the Council

Change letter to the Council to read as follows:

To the Council of The American Society of Mechanical Engineers.

Gentlemen: Your Committee respectfully submits the following revised report on Rules for the construction of, and allowable working pressures on stationary boilers, this report forming a part of the task that has been assigned to it. Stationary boilers as here considered are land boilers and include portable and traction boilers. The Rules do not apply to boilers which are subject to federal inspection and control, such as marine boilers, boilers of steam locomotives and other self-propelled railroad apparatus.

The primary object of the Rules is to secure safe boilers. The interests of boiler users and manufacturers have been carefully considered and the requirements made such that they will not entail undue hardship by departing too widely from present practice.

The Code applies only in part to certain special forms of boilers such as those of the forced circulation or flash type. New matter has been added to state that the material for boilers of this class shall conform to the requirements of the Code, and that other requirements shall also be met except where they relate to special features of construction made necessary in boilers of this type, and to accessories that are manifestly not needed or used in connection with such boilers, such as water gages, water columns, and gage cocks.

In those states and municipalities which have adopted the Boiler Code, your Committee recommends that all requests for interpretations of the Boiler Code be referred to the state authorities having jurisdiction over such matters. In order to maintain uniformity of practice it is also suggested that the authorities having jurisdiction be requested to submit all inquiries where there is any question of doubt to the Boiler Code Committee. Where there is a question respecting the interpretation of the Code, or where constructions apparently are not covered by the Code, it will be most desirable to have the matter referred to the Boiler Code Committee. Unless this procedure is followed, the aim to obtain uniformity in the application of the Code will be defeated. The Boiler Code Committee desires to coöperate to the limit of its ability in assisting in the application of the Code, and will take pleasure in considering all matters where there is any question of doubt that may be brought before it by the various states and municipalities that adopt the Code.

The Committee does not pass on questions concerning specific designs of boilers or appurtenances thereto.

Your Committee recommends that a hearing be held by the Boiler Code Committee at least once in four years at which all interested parties may be heard, in order that such revisions may be made as are found to be desirable, as the state of the art advances.

Yours truly,

John A. Stevens, *Chairman*,

PAGE 5

Heading

Insert above heading of p. 5 the following:

A.S.M.E. Boiler Code

PAGE 7

Heading

Insert above heading of p. 7 the following:

A.S.M.E. Boiler Code

PAGE 8

Par. 9. It has been proposed to add a sentence to Par. 9, as follows:

> Malleable iron may be used when the maximum allowable working pressure does not exceed 200 lb. per sq. in., and the maximum inside diameter or diagonal dimension does not exceed 7 in.

This has been referred to a Sub-Committee of the Boiler Code Committee on Malleable Iron for consideration.

Par. 14. Insert the following at the beginning of Par. 14:

> In determining the maximum allowable working pressure.

PAGE 10

Par. 21. Add to Par. 21 the following:

> Specifications and maximum allowable working pressures for various gages for super-heater tubes shall be the same as for water tubes.

PAGE 12

Par. 29*b*. Strike out the words "or under" from the first line.

PAGE 44

Par. 182. Modification of this paragraph is in the hands of a special Sub-Committee of the Boiler Code Committee of Back Pitch.

PAGF 46

Par. 192. Add new section to Par. 192 as follows:

> *c* The strength of those ligaments between the tube holes which are subjected to a longitudinal stress shall be at least one-half the required strength of those ligaments which come between the tube holes which are subjected to a circumferential stress.

PAGES 55-56

Par. 221. Replace Fig. 15 by revised cut

PAGE 47

Par. 193. Modification of this paragraph is in the hands of a special Sub-Committee of the Boiler Code Committee on Diagonal Ligaments

PAGE 49

Par. 198. Change Par. 198 to read as follows:

> 198 A manhole opening in a dished head shall be flanged to a depth of not less than three times the *required* thickness of the head measured from the outside.

Par. 199. Add the following at the end of Par. 199:

> Acceptable proportions for the ends of through stays are indicated in Fig. 12a.

PAGE 59

Par. 234. Under "where" change derivation of D to read:

> D = least horizontal distance between tube centers on a horizontal row, in.

Immediately below the derivation of letters insert:

> Where tubes are staggered the vertical distance between the center line of tubes in adjacent rows must be not less than $1/2 \sqrt{(2dD + 4^2)}$.

The above formula has been referred to a special Sub-Committee of the Boiler Code Committee.

PAGE 64

Par. 245. It has been proposed to change Par. 245 to read as follows:

> 245 *Cast-iron and Malleable Iron Headers.* The pressure allowed on a water-tube boiler shall not exceed 160 lb. per sq. in. when the tubes are secured to cast-iron headers, nor 200 lb. when the tubes are secured to malleable iron headers. The form and size of the internal cross section perpendicular to the longer axis of a cast-iron or malleable iron header at any point shall be such that it will fall within a 7 in. by 7 in. rectangle.

This has been referred to a Sub-Committee of the Boiler Code Committee on Malleable Iron for consideration.

Par. 251. Change Par. 251 to read as follows:

> 251 The ends of all tubes, suspension tubes and nipples shall be flared not less than $\frac{1}{8}$ in. over the diameter of the tube hole on all water-tube boilers and superheaters, or they may be flared not less than $\frac{1}{8}$ in., rolled and beaded, or flared, rolled and welded.

PAGE 65

Par. 254. Change Par. 254 to read as follows:

> 254 After drilling or reaming rivet holes the plates and butt straps shall be separated, the burrs and chips removed, the plates and butt straps reassembled metal to metal with barrel pins fitting the holes, and with tack bolts.

Par. 256. Change Par. 256 to read as follows:

> 256 Rivets shall be machine driven wherever possible with sufficient pressure to fill the rivet holes, and shall be allowed to cool and shrink under pressure. Barrel pins fitting the holes and tack bolts shall be used. The tack bolts shall be not over 12 in. apart, and a rivet shall be driven each side of each tack bolt before removing the tack bolt.

PAGES 65-66

Pars. 260-261

> The Executive Committee of the Boiler Code Committee will report later respecting openings that need not be reinforced and on methods of reinforcing openings that need not come under the same rules as for manholes.

PAGE 67

Par. 261. Change the two lines of Par. 261 at the top of p. 67 to read:

> l = length of center line of opening in shell in direction parallel to axis of shell plus the sum of the diameters of the rivet holes that come in or adjacent to the center line of the opening, in.

PAGE 69

Par. 272. Change Par. 272 to read as follows:

> 272 Safety valves shall be of the direct spring loaded

pop type with seat and bearing surface of the disc inclined at any angle between 45 deg. and 90 deg. to the center line of the spindle. The valve shall be rated at a pressure 3 per cent in excess of that at which the valve is set to blow.

Safety valves may be used which are constructed with pilot valves or assistant cylinders. Such valves may give any opening up to the full discharge capacity of the area of the opening at the base of the valve, provided the opening of the valve is gradual so as not to induce lifting of the water in the boiler.

All safety valves shall be so constructed that shocks, detrimental to the valve or boiler, are not produced.

The question of the blow-down limit has been referred back to the Executive Committee.

Par. 274. Change Par. 274 to read as follows:

274 The minimum allowable relieving capacity of the safety valve or valves required on a boiler shall be determined on the basis of 6 lb. of steam per hour per sq. ft. of boiler heating surface for water tube boilers. For all other types of power boilers with pressure above 100 lb. the minimum allowable relieving capacity shall be determined on the basis of 5 lb. of steam per hour per sq. ft. of boiler heating surface and on the basis of 3 lb. with pressures at or below 100 lb. per sq. in. The heating surface shall be computed for that side of the boiler surface exposed to the products of combustion, exclusive of the superheating surface. In computing the heating surface for this purpose only the tubes, fireboxes, shells, tube sheets and the projected area of headers need be considered. The minimum number of safety valves required shall be determined on the basis of the minimum allowable relieving capacity and the relieving capacity marked on the valves by the manufacturer.

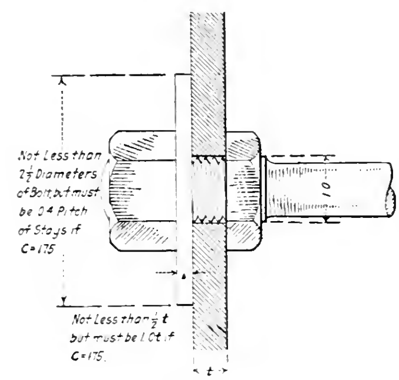

Fig. 12a Acceptable Proportions for Ends of Through Stays

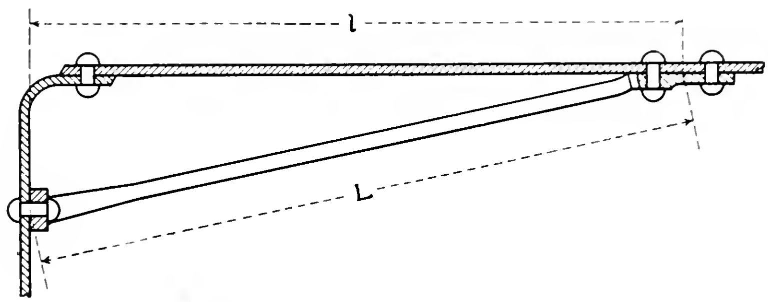

Fig. 15 Measurements for Determining Stresses in Diagonal Stays

PAGE 74

Par. 287. Change Par. 287 to read as follows:

287 When the valve body is marked with the letters A.S.M.E. Std. as required by Par. 273, this shall be a guarantee by the manufacturer that the valve conforms with the details of construction herein specified.

Par. 288. Change Par. 288 to read as follows:

288 Every superheater shall have one or more safety valves near the outlet. The discharge capacity of the safety valve or valves on an attached superheater may be included in determining the number and size of safety valves for the boiler provided there are no intervening valves between the superheater safety valve and the boiler, and provided the discharge capacity of the safety valve or valves on the boiler as distinct from the superheater is at least 75 per cent. of the total valve capacity required.

PAGE 77

Par. 314 Omit the last sentence so that Par. 314 reads as follows:

314 *Feed Piping.* The feed pipe of a boiler shall have an open end or ends inside of the boiler.

Par. 317 Add to Par. 317 the following:

Wherever globe valves are used on feed piping, the inlet shall be under the disc of the valve.

PAGE 79

Par. 332. Change Par. 332 to read as follows:

332 After obtaining the stamp to be used when boilers are to be constructed to conform with the A.S.M.E. Boiler Code, it is understood that a state inspector, municipal inspector, or an inspector employed regularly by an insurance company which is authorized to do a boiler insurance business in the state in which the boiler is built and in the state in which it is to be used, is to be notified that an inspection is to be made and shall inspect such boilers during construction and after completion. At least two inspections shall be made, one before reaming rivet holes and one at the hydrostatic test. In stamping the boiler after completion, if built in compliance with the Code, the builder shall stamp the boiler in the presence of the inspector, after the hydrostatic test, with the A.S.M.E. Code stamp, the builder's name and the serial number of the manufacturer. A data sheet shall be filled out and signed by the manufacturer and the inspector. This data sheet together with the stamp on the boiler shall denote that it was constructed in accordance with the A.S.M.E. Boiler Code.

The name of the state in which the boiler is built shall be stamped under and about one-half inch below the symbol. The name or initials of the manufacturer shall be stamped below the name of the state, together with the serial number of the boiler, and not over one-half inch therefrom. (Samples of data sheets appear in the Appendix, p. ....)

Stamps for the official symbol shown in Fig. 19 are obtainable from The American Society of Mechanical Engineers.

PAGE 80

A.S.M.E. Boiler Code

PART I. SECTION II

[illegible] for low pressure steam and hot water heating and boilers for hot water supply

Par. [illegible]. Change Par. [illegible]15 to read as follows:

[illegible]. A boiler used for low pressure steam heating or [illegible] water supply shall be provided with washout holes [illegible] removal of any sediment that may accumulate [illegible]. Steel shell boilers of the locomotive or vertical fire tube type shall conform to the requirements of Pars. 205 and 206 for washout holes.

Par. 351. Change Par. 351 to read as follows:

351a. No shut-off of any description shall be placed between the safety or water relief valves and boilers, nor on discharge pipes between them and the atmosphere.

b. No boiler for hot water supply shall be connected to a water supply pipe fitted with a check valve or pressure reducing valve.

PAGE 86

Par. 363. Add to Par. 363 the following:

Temperature Regulator. A temperature regulator shall be applied to *hot water* supply boilers which will prevent the temperature from rising above 200 deg. fahr.

PAGE 89

Heading. Insert above heading of p. 89 the following:

PAGE 103

Par. 417

Change first sentence of Par. 417 to read as follows:

417 Figs. 28 and 29 illustrate other joints that may be used in which eccentric stresses are avoided.

Also in Appendix insert the following:

Where repairs are necessary which in any way affect the working pressure or safety of a boiler, a state inspector, municipal inspector, or an inspector employed regularly by an insurance company which is authorized to do a boiler insurance business in the state in which the boiler is used, shall be called for consultation and advice as to the best method of making such repairs; after such repairs are made they shall be subject to the approval of a state inspector, municipal inspector, or an inspector regularly employed by an insurance company which is authorized to do a boiler insurance business in the state in which the boiler is used.

Under Table 3 reference is made to Fig. 31 showing application of Pars. 205, 206 and 207.

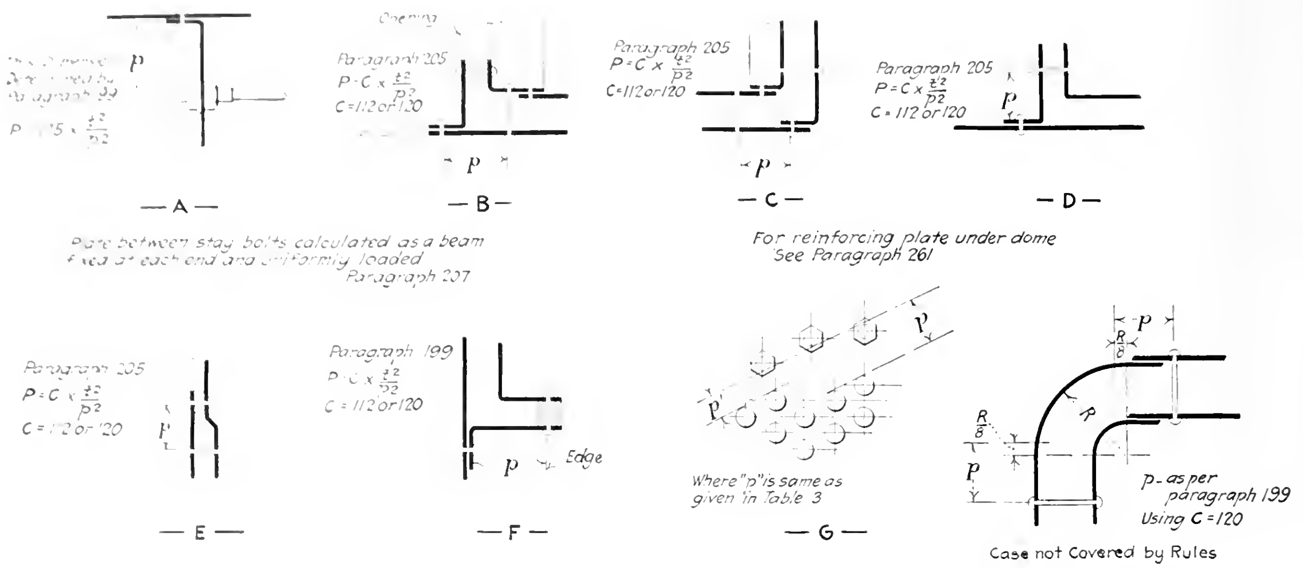

Fig. 31 Details Showing Application of Pars. 205, 206 and 207 to the Staying of Wet-Bottom Boilers

JOINT MEETING OF THE SPECIAL SUB-COMMITTEE ON MATERIAL SPECIFICATIONS

A joint meeting of the special Sub-Committee of the Committee A-1 on Steel of the American Society for Testing Materials and the special Sub-Committee of The American Society of Mechanical Engineer's Boiler Code Committee, appointed to confer on the subject of material specifications, was held in the Engineering Societies Building, New York, on October 26, 1917.

Specifications for Boiler-Plate Steel

It was agreed that 8000-lb. range for tension tests of firebox steel is too small to allow for check tests and that in order to make check tests the range should be 10,000 lb. It

Inspector of Boilers for State or Boiler Insurance Company.

Fig. 33 Rear Side of Data Sheet Form

was then pointed out by those representing the Boiler Code Committee that should the range be made 10,000 lb., the physical requirements for firebox and flange steel would be identical, with the single exception that a homogeneity test is required for firebox and not for flange steel. Those representing the Boiler Code Committee were most earnest in the belief that should the tensile requirements be made the same, something should be introduced into the specifications to further differentiate between the physical qualities of the two grades.

It was proposed that as one of the essential differences between firebox and flange steel is in the amount of discard, a test of material taken from the top of the plate might be employed to show the difference between the firebox and flange grades. The samples for the bending test in the proposed revision are specified to be taken transversely from the middle of the top of the finished rolled material, and it would seem that the requirements for these cross-bending tests could be made more exacting for firebox steel than for flange steel. After considerable discussion it was unanimously agreed that the sub-committees recommend to their respective associations that the tensile range for firebox steel be made 10,000 lb. (55,000 to 65,000 lb.) and that the requirement for the bending tests for firebox steel be made more exacting than for flange steel.

It was further agreed that a recommendation be made that the diameter of the mandrel about which a specimen is bent in the bending tests should depend on the square of the thickness of the plate.

Specifications for Steel Castings

After consideration of the question of the sulphur requirement, it was the sense of the meeting that it would be inexpedient at the present time to make any change in the sulphur requirements for Class B steel castings.

ACTION OF BOILER CODE COMMITTEE

The minutes of the above meeting, which included a tentative rule for the diameter of mandrels to be used in the bending tests and a table of values for various thicknesses of plate, were approved as to form by the Boiler Code Committee at the meeting of Nov. 9. At this same meeting the Boiler Code Committee directed its Sub-Committee to take up with the Sub-Committee of the American Society for Testing Materials the advisability of making homogeneity tests for firebox steel on the samples used for the bending tests, which in the proposed revision are specified to be taken transversely from the middle of the top of the finished rolled material.

The discharge capacity of a flat seat valve of a given diameter with a given lift, may be obtained by multiplying the discharge capacity given in the Table for a 45 deg. bevel seat valve of same diameter and same lift, by 1.4.

In a report upon accidents and accident prevention in machine building, which has just been completed by the Bureau of Labor Statistics, an innovation in the preparation of statistics of this character is introduced to show the seriousness of accidents as well as their frequency. For this purpose, new data are introduced under the title of "severity rates." The result is a collection of illuminating figures which show not only the number of accidents occurring in plant or industry or per thousand of employees, but also the extent to which the working forces employed have been actually incapacitated by injuries incident to their occupations.

A shaft seldom breaks all at once. The conditions that cause the break have been in existence and started the trouble a long time before the final complete rupture comes. The unintentional and undue strain on the shaft every time it jumps in the boxes and the continual heavy strain at regular intervals soon cause a crystallized condition in that part of the shaft where the greatest strain occurs. The crystallization usually begins at a point on the outer circumference of the shaft and travels toward the center. It does not necessarily—and in fact seldom does—affect the entire circumference. At this fragile point, then, a crack is started and as the crystallization grows the crack grows deeper until finally the good metal remaining, no longer able to withstand the strain, breaks. When the broken ends are examined, the fresh break shows only as far as the good metal held on. The original crack may have been started months before, and the constant motion caused the broken parts to rub together until they appear as if they had never been united. Many times the owner of the machine uses the expression, "That was never welded properly," or "The shaft was only partly welded." The common opinion or supposition that crankshafts are welded together is ill-founded. Cranks are generally either drop-forgings or steel castings or made by cutting them out of solid steel billets, and no welding process whatever enters into their formation.—*Power.*

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

THE offices of the Society are particularly busy at this time and all the departments are carrying an overload. About 20 per cent of the membership are directly or indirectly engaged in war activities. This means that the Society is without the services of nearly 2000 members, and, as might be expected, it is always the most active ones—not only in this Society but in other organizations generally—who are the first to offer themselves for the service of their country. The result has been that many adjustments in personnel of committees and provisions for taking care of committee and section work, have had to be made.

The Committee on Meetings has lost the opportunity for consultation with Major John H. Barr, who is now in Washington in the trench-warfare division of the War Department in charge of bombing devices.

The Publication Committee has lost Prof. J. W. Roe, who is working for the Government on specifications and rules for instruction for aviation work. The Chairman of the Committee, Mr. Fred R. Low, reports that he is greatly handicapped by a depletion in his staff.

The Committee on Sections has lost Mr. Whitlock who is a Major in the Engineer Officers' Reserve Corps. The personnel of the Executive Committees of several of the Sections has been depleted by war activities.

The New York Section Committee which, in addition to its regular meetings work, is in charge of the entertainment at the forthcoming Annual Meeting, has had to get along without Messrs. Swan, Prindle and Blake. Mr. Swan has a commission in the Engineer Officers' Reserve Corps, and Mr. Blake is in Washington working in the Ordnance Department.

Prof. W. B. Gregory, another member of the Council and a member of the New Orleans Section Committee, is now in France reporting directly to General Pershing. Mr. John Hunter, of the St. Louis Section Committee and Vice-President-elect, is on the Emergency Shipping Board. The Worcester Section Committee has lost two members in the persons of Messrs. Richard G. Williams and E. Howard Reed. The Erie Section has lost its chairman, Mr. J. F. Wadsworth.

Mr. George M. Brill, member of the Committee on Student Branches, is a Major in the Engineer Officers' Reserve Corps and Prof. W. D. Ennis, chairman of the Brooklyn Polytechnic Institute Branch, has a similar commission.

Mr. Park A. Dallis, chairman of the Atlanta sub-committee on Increase of Membership, is a Captain in the Engineer Section of the Officers' Reserve Corps.

Many of the special committees of the Society are depleted for this same reason of war activities. Mr. Ralph D. Mershon, member of the Research Committee, is a Major in the Engineer Officers' Reserve Corps. Prof. Lionel S. Marks, chairman of the Sub-Committee on Clinkering of Coal of the Research Committee, has been in Washington for some time as internal-combustion-engine expert for the Government.

Prof. Carl C. Thomas, member of the Research Committee and chairman of the Sub-Committee on Air Machinery of the Committee on Meetings, is now manager of machinery fabrication for the American International Shipbuilding Corporation.

Mr. Charles Day, member of the Sub-Committee on Industrial Buildings, is a member of the Production Committee of the Emergency Fleet Corporation and is now in England.

Mr. W. S. Gifford, member of the Joint Committee of Standards for Graphic Presentation, is Director of the Council of National Defense.

Mr. Edwin B. Katte, member of the Sub-Committee of Railroads, is a Major in the Engineer Officers' Reserve Corps.

These changes in committees have, of course, produced additional loads on the members left behind, but in all cases handicaps have been satisfactorily met.

Of the departments in the office, the Year Book Department has been rather severely taxed by the unusually large number of changes in addresses caused by members going into active service, coupled with the normal increase in membership in the Society, which has been sustained and has, so far, suffered no change on account of the war. The Publication Committee hopes to have the Year Book out on time and in good shape.

The Secretary's office has been unusually active in connection with the Annual Meeting which, as was anticipated, has been a very difficult one to prepare for. The Committee on Meetings is desirous of making the forthcoming convention a memorable one in the annals of the Society and at the same time bring out the service which the engineer can render the public at this critical time. Details of the program this year have been very difficult to consummate on account of the inability of prominent men to make promises in advance.

The Sections Department has also been particularly busy in maintaining this activity in the face of war conditions which have precluded many of the active Section members from contributing their normal work.

The number of callers at the office has been exceptionally heavy during the month, practically two-thirds of those coming in requesting information regarding service to our country.

The increased activity in the Employment Department, which commenced about three months ago, has been maintained and this department is taking care of at least twice the amount of its normal work. This department is coöperating with the Committee on Engineering Resources, in supplying the Government with large numbers of trained specialists.

CALVIN W. RICE,
Secretary.

The New York Alumni Associations of various colleges where technical courses are given will again hold reunions during the Annual Meeting. The following colleges are among those which have planned reunions for "College Reunion night," this year on December 7: Massachusetts Institute of Technology, Pennsylvania State College, Purdue University, Worcester, Polytechnic Institute. Other colleges will also hold these "get-together" functions, and complete announcement will be made in the final program.

ANNUAL MEETING PROGRAM

New York, December 4 to 7, 1917

Tuesday, December 4

12:00 m. Opening of Registration Bureau in Engineering Societies Building

12:30 p.m. Conference Luncheon, Council and Sections Delegates

2:[illegible] p.m. Council Meeting

2:[illegible] p.m. Meeting of Gage Committee

2:00 p.m. Sections Conference

8:30 p.m. Report of Tellers of Election and Introduction of the President-elect
Conferring of Honorary Membership upon Major-General George W. Goethals, followed by an address by Hon. William H. Taft
Reception by the President and the President-elect

Wednesday, December 5

9:45 a.m. Business Meeting: Amendments to the Constitution and By-Laws; Reports of Standing Committees; Address on the Activities of the Society for 1917, by President Hollis; Presentation to the Society of a Bust of Admiral B. F. Isherwood; Reports by Sub-Committees of the Research Committee

The consent of the meeting will be asked to adjourn the business meeting to Thursday morning in order to allow time for the addresses of the Keynote Session.

10:00 a.m. Keynote Session on The Service of the Engineer to the Public in Times of Crises

Universal Public Service in Peace and War, Dr. Ira N. Hollis, President of the Society. Other addresses will be given by distinguished men of national reputation on the following subjects relating to problems incident to the war: Coöperation of Engineers; The Agricultural Problem, The Fuel Problem; Engineering Research; Special Education in War Time; Building a Merchant Marine; Rail Transportation; Motor Transportation; The Aircraft Problem; Cantonments. This will be an all-day session.

12:30 p.m. Buffet Luncheon

2:00 p.m. Continuation of Keynote Session on The Service of the Engineer to the Public in Times of Crises

2:30 p.m. Simultaneous Sessions

POWER-PLANT SESSION

Preventable Waste of Coal in the United States, David Moffat Myers

A Commercial Analysis of the Small Turbine Situation, W. J. A. London

Bagasse as a Source of Fuel, E. C. Freeland

The Cooling of Water for Power-Plant Purposes, C. C. Thomas

The Steam Motor in the Automotive Field, E. T. Adams

GENERAL SESSION

The Transfer of Heat Between a Flowing Gas and a Containing Flue, Lawford H. Fry

A Study of Surface Resistance with Glass as the Transmission Medium, H. R. Hammond and C. W. Holmberg

Apparatus for Cooling, Drying and Purifying Air, W. J. Baldwin

Recent Developments in Balancing Apparatus, N. W. Akimoff.

Plotting Blower-Test Curves, A. H. Anderson *(By title only.)*

Cross-Current Predeterminations from Crank-Effort Diagrams, Louis Illmer *(By title only.)*

INDUSTRIAL-SAFETY SESSION

Two codes will be presented for discussion by the Sub-Committee on Protection of Industrial Workers, on Safety Standards for Elevators and Woodworking Machinery

3:[illegible] p.m. Meeting of Committees on Increase of Membership

3:[illegible] p.m. Ladies' Reception and Tea

(Continued on Next Page)

Wednesday, December 5 (*Continued*)

4:30 p.m. Student Branch Conference

8:15 p.m. Smoker

Get-together meeting for members. Mr. John R. Freeman, Past-President Am.Soc.M.E., will give an illustrated talk upon his trip to the Orient taken last winter with Dr. John A. Brashear and Mr. Ambrose Swasey, Past-Presidents Am.Soc.M.E. Music by Glee Club. Refreshments

Thursday, December 6

9:45 a.m. Business Meeting continued, followed by General Sessions

LOCAL-SECTIONS SESSION

This session will be held under the direction of the Sections Committee, for a discussion of the work of the Sections and of Society Affairs, by representatives of the 24 Sections of the Society

GENERAL SESSION

An Account of the Engineering Work of E. D. Leavitt, F. W. Dean

An Exact Volume Regulator for Blast Furnace Engines, L. C. Loewenstein

Expenses and Costs, H. L. Gantt

The following papers contributed by Local Sections will be presented by title:

By-Product Coke and Coking Operations, C. J. Ramsburg and F. W. Sperr, Jr.

The Submarine, C. H. Bedell

Combined Stresses, A. L. Jenkins

The Trumble Refining Process, N. W. Thompson

10:00 a.m. Joint Meeting of A.S.M.E. and S.A.E. Committees on Steel Roller Chains

12:30 p.m. Luncheon, at which there will be an address on The Relation of Industrial Management to Engineering, by Prof. Dexter S. Kimball

2:30 p.m. Simultaneous Sessions

MACHINE-SHOP SESSION

Under the auspices of the Sub-Committee on Machine Shop Practice

Topical Discussion on the subject of Inspection with the following introductory discussions:

The Logic of Inspection, A. L. DeLeeuw

The Relation of Inspection to Product, F. A. Waldron

General Principles of Government Inspection and Relations Between Inspectors and Manufacturers, Col. B. W. Dunn

TEXTILE SESSION

Under the auspices of the Sub-Committee on Textiles

Labor-Turnover Records and the Labor Problem, Richard B. Gregg

Accident Prevention in the Textile Industry, David S. Beyer

The Moisture Content of Textiles and Some of its Effects, William D. Hartshorne

8:30 p.m. Lecture and Annual Reunion

The Beautiful in Commonplace Things, Dr. John A. Brashear. Following the lecture there will be a reunion and dance, with refreshments, on the fifth floor of the Engineering Societies Building

Friday, December 7

10:00 a.m. Simultaneous Sessions

MANAGEMENT SESSION

Topical discussion on the Employment of Women in the Skilled Industries, with particular reference to war conditions. To be introduced by Mr. John W. Upp, General Electric Co., and Mr. C. B. Lord, Wagner Electric Manufacturing Co.

The Engineer, the Cripple and the New Education, by Major Frank B. Gilbreth

POWER-TEST HEARING

A public hearing by the Power Test Committee, preliminary to a proposed revision of the Power Test Code of the Society, comprising rules for conducting tests on prime movers of different types, and auxiliary apparatus

2:00 p.m. Council Meeting

8:00 p.m. College Reunions

THE ANNUAL MEETING

THE Annual Meeting this year will be different from any [illegible] held by the Society. Upwards of one [illegible] members of the Society will come together at their [illegible] a remarkable program will be carried out. [illegible] which will pervade the meeting rooms, the [illegible] where the members group together [illegible] for war. The discussions at the meetings, and [illegible] of the Keynote Session, the Machine Shop Session and the Sections Session will center on this same topic. It will be uppermost in the minds of those attending committee meetings, for the regular committees have been seriously [illegible] by the absence of members in active service and new committees have been appointed expressly for service to the Government at this critical time. The New York Section is not giving out the secret as yet, but even the social events of the meeting will be interspersed with patriotic exercises.

Everyone who comes to the convention will go away with impressions, not on the theory and practice of machines, nor with a better knowledge of power plants, nor of the latest developments in technical research as such, but on the practice of war—engineering war. All other questions are in abeyance at this time and the one justification for calling busy members of any large organization into convention at such a time as this is to have them bring up, discuss, settle and go away to act upon their war problems.

And what an opportunity for both gathering and disseminating information on war problems this occasion offers! Over a thousand engineers and specialists, most of whom are engaged in the vital work of the prosecution of the war will take the time to get together, not for their mutual good, but for the good of the country they have the honor to serve! Who can prescribe the limits to the benefits of this meeting? One question solved at this convention may effectualize the work of hundreds of war helpers.

Many persons have doubted the wisdom of calling large meetings at this time and the Government has expressed its general disapproval of such meetings when not essential to the public good. But the Spring Meeting of our Society in Cincinnati demonstrated strikingly that considerable benefits could accrue and no disadvantages follow from continuing the General Meetings of the Society and so there has been no question as yet of discontinuing them. We must have coöperation at this time. More than that we must have cohesion which means something much more intense, and which can only result from the most intimate contact of engineering elements. The engineers, heads of large plants putting out great quantities of munitions, supervisors of enormous tasks of providing agricultural machinery, means of transportation, aeroplanes, ships and more ships, are the elements in this case, and they must all cohere. This convention offers the opportunity and every member of the Society owes it not alone to himself, to his fellow member, nor to his Society, to attend the Annual Meeting; but he owes it to his country and to democracy.

The program of the meeting appears on the two preceding pages. Publication of the papers began in the October issue of The Journal and has been continued in the succeeding issues.

Authors of the Papers

EDWARD T. ADAMS has had a long experience in the design of large steam units and great gas-engine plants. More recently he has been chief designer for companies manufacturing modern tractors. At present his time is devoted to investigations of the use of steam, heavy oil and gasoline engines in the automobile and other fields.

NICHOLAS W. AKIMOFF has specialized in various applications of dynamics to mechanical engineering. His first paper on Dynamic Balance was presented to the Society at the Spring Meeting, 1916. His recent book on Lagrange's Equations was reviewed in The Journal.

A. M. ANDERSON, during his thirteen years' connection with the Armour Institute of Technology, has been instrumental in the development of a new form of pitot tube for air and gases. His other engineering activities have been principally in pneumatics and hydraulics, covering determinations of velocities in ventilation ducts, compressed-air pipes, gas pipes, and water meters, current meters, and anemometers.

WILLIAM J. BALDWIN was a member of the Society's Committee which first formulated the American Standard Pipe Thread, the Briggs formula, and it was he who was responsible for bringing the Briggs system to the attention of the committee. He has been engaged in consulting-steam-engineering practice in New York City for many years, and the apparatus for mechanically drying air described in his paper is the result of his experiments to overcome and abate the smoke and dust nuisance in Manhattan.

C. H. BEDELL was for twenty years head of the electric laboratory of the Electro Dynamic Company, during which time the inter-pole adjustable-speed motor was developed. For the last nine years he has served as electrical engineer for the Electric Boat Co.

DAVID S. BEYER was for eleven years in charge of technical survey of plants and fire insurance, and later chief safety inspector of the American Steel & Wire Co. He is the author of a number of papers on accident prevention. He presented a paper on Recent Application of Safety Devices for Textile Machinery at the annual congress of the National Safety Council in New York this year.

ADOLPH L. DeLEEUW writes from a very extended experience, having been designing engineer with the Niles Tool Works Co., mechanical engineer with the Cincinnati Milling Machinery Co., and at present is mechanical engineer with the Singer Manufacturing Co. He has written quite a number of papers on the important subject of metal cutting and metal cutters.

F. W. DEAN, who writes on the work of Mr. E. D. Leavitt, was associated with Mr. Leavitt for several years. Since that time he has been practising mill engineering and architecture in Boston, dealing with mill construction, steam plants, water power, and general consulting and expert engineering. Since the date of his joining the Society in 1883 Mr. Dean has contributed voluminously to its proceedings.

LAWFORD H. FRY is now general inspector of the Standard Steel Works Co. In 1908 he contributed to the Institution of Mechanical Engineers a paper on Combustion and Heat Balances in Locomotives, which was one of the first analyses made of the experiments on the Pennsylvania Railroad locomotive-testing plant. Since then he has contributed a number of papers to technical societies and to technical journals dealing with various aspects of locomotive operation, paying particular attention to the action of the boiler. His later work has been largely connected with the heat-treatment of steel.

HENRY L. GANTT, consulting enigneer, was associated with the late Frederick W. Taylor in the initial stages of development of the latter's system of industrial management, and for more than the past ten years has given his professional attention to administration, management, and other subjects which confront the

industrial engineer. He has presented many valuable papers on management and kindred topics before the Society, and has otherwise embodied his ideas in published works that have become a part of the authoritative literature on the subject.

FRANK B. GILBRETH, now a Major in the Engineer Officers' Reserve Corps, has been particularly active of late in connection with the problem of taking care of soldiers crippled in the war, and using them in the industries. Mr. Gilbreth was recently successful in securing official recognition of this work, and is now devoting his whole time to this problem.

RICHARD B. GREGG was during the summer of 1916 in direct charge of an investigation into the hours, wages and working conditions of some 500 shops in the dress and waist industry of New York City. In addition to consulting and organizing work, he has thoroughly studied for the employers the labor situation in a number of textile mills and establishments in other industries.

WILLIAM D. HARTSHORNE can claim a thirty-four years' experience with textile-mill conditions. For twenty years of this period he was employed in the respective capacities of chemist, manager of dyeing and finishing department, and as general superintendent of the worsted department of the Arlington Mills at Lawrence, Mass. For the last fourteen years of this service he was resident agent of the Textet Corporation, covering both worsted and cotton departments. He has contributed a number of papers concerning textile-manufacturing problems and mill conditions to the proceedings of several societies.

LOUIS ILLMER, who has specialized as gas and oil-engine expert for the past fifteen years, is now engaged in high-speed development work for Mr. Simon Lake, the submarine expert at Milford, Conn. Prior to this work, he developed the Illmer gas-engine and complete producer-plant equipment for the Reading Iron Co., Reading, Pa. The results of some of his rather extensive research studies into the fine points of engine design are embodied in a number of papers.

A. LEWIS JENKINS, of the University of Cincinnati, has made a number of contributions on the strength of punch and riveter frames, and stresses due to bending and twisting, and has done considerable work on the stress relations in pressed fits. He was the first to publish the present accepted formulæ for the design of pressed fits. He has written several articles on hydraulic presses, intensifiers, accumulators and pumps.

LOUIS C. LOEWENSTEIN has had a varied experience in designing machinery for marine use with several large shipbuilding and other concerns. He was for six years in charge of instruction of machine design and steam-engineering subjects at Lehigh University. Since 1907 he has been engaged in design and theoretical engineering of steam turbines and centrifugal compressors with the General Electric Co., at Lynn, Mass.

W. J. A. LONDON served his apprenticeship with Sir Charles A. Parsons on turbine work and was later connected with the Brown-Boveri Co., in Switzerland doing the pioneer work of introducing steam turbines on the continent. He was at one time special research engineer on turbine work for Mr. George Westinghouse, and was for seven years chief engineer of the Terry Steam Turbine Co. He is at present engaged in developing a new design of steam turbine known as the steam motor.

CHESTER B. LORD, general superintendent of the Wagner Electric Co., has had a long connection with the construction, layout and equipment of new plants. He was for six years general foreman in charge of tools, dies and special machines of the General Electric Co.

DAVID MOFFAT MYERS is a member of the firm of Gregg & Myers, Consulting Engineers of New York City. He has devoted much attention to the use of special fuels, such as tan-bark, chestnut-chips and bagasse, especially in the plants of the United States Leather Co.

CHARLES J. RAMSBURG was connected for seventeen years with the United Gas Improvement Co., of Philadelphia, in various capacities, and for nine years as assistant engineer of works in charge of daily operation of Philadelphia gas works. He has presented numerous papers before the American Gas Institute on general technical subjects connected with the gas industry, and was awarded the Beal Medal by the Institute in 1910 for his paper on Gas Purification. He became associated with H. Koppers Co., in 1913 in the capacity of vice-president, and since that time has contributed a number of papers on by-product coke-oven subjects.

FREDERICK W. SPERR, JR., now chief chemist of the H. Koppers Co., started in the by-product coke-oven business in 1910 as a chemist for the first plant of Koppers ovens in America, the plant of the United States Steel Corporation at Joliet, Ill. He has subsequently been chief chemist of the Fairfield plant of the Tennessee Coal, Iron & Railroad Company and of the blast furnace and coke department of the Inland Steel Company, both of these companies operating Koppers plants.

CARL C. THOMAS was for a number of years on the Atlantic Coast in charge of marine-machinery design at the Maryland Steel Co., Sparrows Point, and connected with building of merchant and naval vessels. He was called to Cornell University as professor of marine engineering in 1904, to the University of Wisconsin as professor of steam engineering in 1908, and to Johns Hopkins University in 1913 as head of the Department of Mechanical Engineering, from which institution he is now on leave of absence. He is the inventor of the Thomas meter, which has been described in the TRANSACTIONS of the Society.

JOHN W. UPP has been connected with the General Electric Co., at Schenectady, for seventeen years. He began in the engineering department and was later placed in charge of the drafting department; he is now manager of the switchboard department. He is a member of the Society's special committee on Standard Cross-Sections and Symbols.

FREDERICK A. WALDRON has had experience with the Brown & Sharpe Manufacturing Co., Beaman & Smith and the Yale & Towne Manufacturing Co. With the last mentioned company he worked his way up to the position of superintendent. He has been practising as an industrial engineer for some years, and is chairman of the sub-committee on Industrial Buildings of the Society.

Power Test Hearing

On Friday morning, December 7, of the Annual Meeting there will be one of the most important sessions in respect to standardization that this Society has ever held. This will be a public hearing by the Power Test Committee, held in pursuance of a requirement of the Council that this Committee should hold meetings from time to time at which interested parties may have an opportunity to present suggestions for purposes of revision.

The Power Test Codes were formulated by the Power Test Committee in 1915 and were published in Volume 37 of the TRANSACTIONS. They comprise rules for conducting performance tests on boilers, engines, turbines, pumps, compressors, blowers, complete steam plants, locomotives, gas-power apparatus and water wheels.

The Power Test Committee will welcome a thorough discussion of the Rules in the hope that they may be made of the greatest value to manufacturers and users of power-plant apparatus and to the profession generally.

The different sections of the Codes will be taken up in detail to facilitate suggestions which later will be considered by the Committee as material for the revision of the Codes.

Invitations have been extended to over fifty societies to send delegates, and colleges, railroads, manufacturing firms, and testing laboratories have also been asked to send representatives.

REPORTS OF STANDING COMMITTEES

THE reports of Standing Committees of The American Society of Mechanical Engineers will be presented at the forthcoming Annual Meeting as an appendix to the Annual Report of the President of the Society's activities for the year. The Standing Committee reports are published below:

Reports of Finance Committee

The Finance Committee reports that the income of the Society for the year ending September 30, 1917, was $207,016.98. The total expenditures chargeable to income were $186,547.57, leaving an excess of income over expenditures of $20,499.41, this being a net balance after reserving $14,000 for obligations undertaken but not yet completed.

The expenditures of the Society per member for the fiscal year just closed are as follows:

General Salaries	$ 2.06
Headquarters, Library, Supplies, etc.	1.84
Committees on Membership and Increase of Membership	1.27
Sections	.98
Council contingencies, mileage and employment	.77
House Committee	.40
Meetings, Annual and Spring	1.18
Year Book	.63
Journal and Condensed Catalogues	8.47
Transactions	2.42
Other activities	2.73
Making a total of	$22.75

The recommended Budget Appropriation for the year 1917-1918 is as follows:

Finance Committee		
Administrations	$ 22,700	
Occupancy of Building and Engineering Council	8,800	
Library	4,000	
		$ 35,500
Membership Committee		2,900
Council		
Contingencies	3,000	
Committees not otherwise provided for	6,700	
Mileage	2,200	
Employment Bulletin	2,400	
		14,300
Sections Committee		10,750
Increase of Membership Committee		8,300
House Committee		4,335
Meetings Committee		10,265
Publication Committee		104,405
Research Committee		500
Students' Committee		1,000
Junior Prizes Committee		75
Sales Expenditures		11,000
John Fritz Medal Board of Award		75
Engineering Resources Committee		1,500
Coöperation and Organization Committee		100
Public Relations Committee		500
Total		$205,505

The estimated income for the year 1918 is $228,500.

Appended will be found reports of the accounts of the Society as shown in the books for the fiscal year ending September 30, 1917.

Respectfully submitted,

R. M. DIXON, *Chairman,*
A. E. FORSTALL,
GEO. M. FORREST,
W. D. SYMONS,
Finance Committee.

REPORT OF ACCOUNTS

MR. R. M. DIXON,
CHAIRMAN, FINANCE COMMITTEE.

DEAR SIR:

In accordance with your instructions, we have examined the books and accounts of The American Society of Mechanical Engineers for the twelve months ended September 30, 1917.

The results of this examination are set forth in the three exhibits attached hereto, as follows:

Exhibit A Balance Sheet, September 30, 1917.
Exhibit B Income and Expenses, for the twelve months ended September 30, 1917.
Exhibit C Receipts and Disbursements for the twelve months ended September 30, 1917.

We hereby certify that the accompanying Balance Sheet is a true exhibit of its financial conditions as of September 30, 1917, and that the attached statements of Income and Expenses, and Receipts and Disbursements, are correct.

Respectfully submitted,

(Signed) WM. J. STRUSS & CO.,
Certified Public Accountants.

EXHIBIT A

BALANCE SHEET, SEPTEMBER 30, 1917

RESOURCES

Equity in Society's Building (No. 25 to 33 West 39th Street)	$365,846.62	
Equity in one-third of Cost of Land (No. 25 to 33 West 39th Street)	180,000.00	
		$545,846.62

Cash on hand and in Banks		
General and Trust Funds, September 30, 1917	36,901.15	
		$267,671.31

[1] Note: The item of total expenses includes $14,000 not yet paid to complete work already in progress and chargeable to this year's activities.

Report of Committee on Meetings

Professional Sessions

Although it has been the aim of the Meetings Committee to maintain a high standard for papers presented and discussed at the professional sessions of general meetings, the Committee has realized that many members of the Society regard of equal importance the opportunities afforded for personal conferences, for special committee meetings, for discussion of problems of peculiar interest to a limited number only, and for bringing about a personal contact among the members of the Society that is becoming truly national. With these points in view the Committee has ever before it the idea of so balancing the programs at the meetings that they shall not be overburdened with detailed technical papers, and would emphasize as a guiding principle for the future the wisdom of somewhat limited, carefully chosen programs stimulating general discussion, in preference to sessions overburdened with an unduly large number of papers.

Keynote Session

Besides a number of professional sessions devoted to the interests of various specialties of the members, it has been the aim of the Committee for the past few years to have during each Annual and Spring meeting a so-called "keynote" session which should offer an opportunity for the presentation of the broad but timely problems of general interest. With these points in mind, Industrial Valuation was chosen as the general theme for the keynote session of the Annual Meeting, December 1916.

As the Spring Meeting of 1917 came shortly after the declaration of war, the Committee felt that perhaps the most timely subject was the manufacture of munitions. The large attendance at the Cincinnati meeting is in part attributed to the announcement of this important subject and partly to the exceptional opportunity afforded the members of the Society to coöperate with the members of the National Machine Tool Builders' Association, with whom a joint session was arranged.

So important has become the relation of the engineer to the problems resulting from the war that the Committee has chosen for the keynote session of the coming Annual Meeting, December 4 to 7, 1917, Service of the Engineer to the Public in Times of National Crises.

Special Exercises

In connection with the Annual Meeting, December 1916, special memorial exercises were held in honor of John E. Sweet, the beloved founder of the Society.

At the coming Annual Meeting, December 1917, there will be special exercises in connection with the conferring of honorary membership upon Major-General George W. Goethals, upon which occasion the address of the evening will be delivered by William H. Taft, ex-President of the United States.

Social Functions

At the Annual Meeting of 1916 all social events were held in the Engineering Societies Building. Owing to this fact the democratic spirit of the Society was more keenly developed, as more freedom was felt on the part of the members and guests in attending these various functions. The spirit of good fellowship thus promoted is a distinct asset to the Society.

The success of the smokers held the last two years has prompted the Committee to arrange for the repetition of this part of the program for the Annual Meeting of 1917, with such modifications as past experience has shown would be desirable.

The delightful functions provided in connection with the Spring Meeting at Cincinnati were all in accord with the aims of the Committee on Meetings to promote the most cordial democratic spirit among the members.

Inspection Trips

It is the belief of the Committee that inspection trips to various points of engineering interest should be continued in connection with both the Annual and the Spring Meetings. It is the feeling of the Committee, however, that a small number of such trips thoroughly organized is distinctly more beneficial and pleasanter for the membership than a large number of informal trips, offering too large a variety of opportunities.

Attendance at Meetings

Evidences of the broader field of activity of the Society are apparent in the attendance at the Annual and Spring Meetings. The total registration at the Annual Meeting, December 1916, was 1868, the largest in the history of the Society. Of this number 953 were members and 915 were guests. The number of members present represented 12.5 per cent. of the total membership, and exceeded that of the Annual Meeting of 1915 by 431.

It is somewhat more difficult to compare the figures of attendance at the Spring Meetings, owing to the fact that the geographical location of the meeting has a distinct bearing upon attendance, but it is interesting to note that the attendance at Cincinnati in 1917 broke all previous spring-meeting records, the total registration being 868, of which 410 were members and 458 guests.

Sub-Committees of the Meetings Committee

The work of the sub-committees of the Committee on Meetings has for the most part been exceedingly satisfactory. It stimulates a wide interest in the work of the Society and results in the presentation of excellent papers and discussions. The Committee feels that it is wise to continue those sub-committees that keep alive and awake to their opportunities, but it also believes it unwise to appoint too many such committees on account of the danger of overspecialization and the possibilities of unwieldly programs.

Respectfully submitted,

ROBERT H. FERNALD, *Chairman,*
L. P. ALFORD,
JOHN H. BARR,
DEXTER S. KIMBALL,
A. L. DE LEEUW.
Meetings Committee.

Report of Publication Committee

During the year THE JOURNAL has been developed by extending the Engineering Survey to include engineering activities outside of those of our own or other societies, especially in the way of engineering research. The Review of Engineering Periodicals has been broadened to include publications in English as well as in the foreign languages. Reviews, written by specialists in their several fields, have been published of

notable additions to the literature of our subject. Mr. C. M. Sames has been added to the editorial staff. The makeup and distribution of The Journal for the first seven months of 1917 were as follows:

Makeup of The Journal, 1917

Technical Section	48 per cent
Society Affairs	19 per cent
Engineering Survey	33 per cent
	100 per cent

Distribution of The Journal, 1917

To Members	8250 copies per month
Exchanges	250 copies per month
Subscriptions	450 copies per month
Advertisers	300 copies per month
Students	500 copies per month
	9750 copies per month

The cost of publishing The Journal for the fiscal year ending October 31, 1917, was about $53,428, and its income from advertising about $34,928, leaving a deficit of about $18,500. No credit is given to The Journal for copies sold to subscribers and furnished, in partial return for their dues, to the membership and student branches. These, furnished at present to the number of over 9000, at $3.00 per year to subscribers and $2.00 to the membership, would more than cover the apparent deficit and show The Journal to be paying its own expenses.

It is the purpose of the Committee to make The Journal an epitome of current information in the field of mechanical engineering, and to devote to this service whatever revenue the paper may produce.

The last issue of Condensed Catalogues cost about $15,500 and brought in a revenue of about $29,000, making a profit of about $13,500. It has been improved by the addition of an index of manufacturers of mechanical equipment.

In 1913 the Committee was allowed an appropriation of $750 for indexing the Transactions. To this has been added $350, making $1100 in all. It was pointed out when these appropriations were asked for that they would meet the expenses only of preparation, but not of publishing. We are now able to report the complete indexing of Transactions from Volume I to date in card form. To publish this in book form will cost about $2000 plus 90 cents per copy, thus:

Estimated Cost of Transactions Index

For 2000 copies	$2000
2000 x 90 cents	1800
	$3800
For 10,000 copies	$2000
10,000 x 90 cents	9000
	$11,000

These ought to be furnished free to the membership as they have been in the past, and we recommend that the Committee be authorized to expend not to exceed $2000 in printing it with a view to its distribution when the necessary funds become available.

It has been the practice of the Society to preserve all undistributed copies of Transactions and of the separate papers. The accumulation is becoming burdensome, and the Committee has decided to retain not over 25 copies of each volume of the Transactions up to and including Vol. XXV and 100 copies each of Vols. XXVI to XXXIII inclusive. Several of the earlier volumes are completely exhausted and the Society is seeking them at a premium. No more than the reserved number of any volume are on hand in the bound form. The surplus will be sold to those desiring them at $2.50 per volume in paper covers, or at $2.00 gathered and stitched ready for binding.

With the increased appropriation at the disposal of the Committee for the coming year, we hope to make the publications of the Society, especially The Journal, of still greater benefit to the membership.

Respectfully submitted,

Fred. R. Low, *Chairman,*
C. I. Earll,
George J. Foran,
Fred. J. Miller,
Joseph W. Roe,
Publication Committee.

Report of Standardization Committee

The Standardization Committee is charged with a general oversight of the standardizing activities of the various committees within the Society. That means that it does not concern itself with any of the details of the actual work of standardizing, but rather with the work being carried on by other committees according to a general routine and principles adopted by the Society. It concerns itself further with the promotion of interrelation of the activities of the various committees where that seems advisable.

In carrying out its duties this Committee has interpreted its mandate to exercise the least possible authority so far as committees were concerned that were appointed before its creation.

With regard to committees appointed after the creation of this Standing Committee, the latter has confined itself strictly to suggestions made directly to the Council as to the personnel and general routine activities of the various special committees.

The most important activity of the Standardization Committee has been its work in connection with the creation of an American Engineering Standards Committee. Active in this work were jointly the American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Society for Testing Materials. Delegates from these societies created an Executive Committee consisting of one member from each and this committee reported a Constitution and By-Laws to the main Joint Committee, which latter accepted the report and caused it to be sent to the founder societies for their action.

Approval was given to this by all except the American Society for Testing Materials, and that approval is expected as soon as its governing body meets this fall. A copy of the American Engineering Standards Committee's Constitution and By-Laws is appended. A careful study of this Constitution is recommended, as it is probably the beginning of what is hoped will eventually fill a very important national and international need. It is expected that with time every technical association or society, whether of an engineering or other nature, not only in the United States, but abroad, will participate in the work of this committee. A beginning in this direction has already been made in that the British Engineer-

[illegible] Standards Committee has invited this American Engineering Standards Committee to send delegates to London to consider a change in the British standard Whitworth thread [illegible] complete cross section of the United States screw thread, and to consider also the question of metric threads.

It is gratifying to note that the suggestions made by the [illegible] of our own Committee while that was a special committee on standardization, formed the basis in the formulation of the Constitution of this American Engineering Standards Committee and have to a considerable extent been adopted by it.

Respectfully submitted,

Henry Hess, *Chairman*,
H. L. Gantt,
W. F. Kiesel,
Carl Schwartz.
Standardization Committee.

Report of Library Committee

Your Library Committee has the honor to present the following report for the year ending September 30, 1917.

As the library of the Society has been incorporated in the United Engineering Society Library, the duty of the Committee has been to represent the Society on the Library Board of that organization, and this report summarizes briefly the work of the United Engineering Society Library during the year.

The Library contained 49,702 volumes and pamphlets on October 1, 1916, and 132,070 on September 30, 1917. The extraordinary increase is due to the absorption of the library of the American Society of Civil Engineers which occurred in February 1917, and which added 67,242 volumes and pamphlets to the collection. Of the current accessions, 206 were presented through The American Society of Mechanical Engineers.

In March, Mr. W. P. Cutter presented his resignation as Librarian, which was accepted. Mr. H. W. Craver, Librarian of the Carnegie Library of Pittsburgh, was elected to fill the vacancy, and assumed the duties of the position on April 1. The title of the position was changed to Director of the Library at this time.

The number of readers during the year was 12,710.

In addition, the Library Service Bureau has met the needs of inquirers by preparing bibliographies and translations, and by copying articles. This branch of the work shows a steady gain in volume as engineers become more familiar with its advantages.

Respectfully submitted,

John W. Lieb, *Chairman*,
Jesse M. Smith,
Walter M. McFarland,
A. M. Hunt,
Calvin W. Rice.

Report of Membership Committee

The Membership Committee held nine meetings during the year 1916-1917.

The number of applications considered in the transaction of its work and a summary showing the action taken, follows:

Applications pending October 1, 1916	700
Applications received during the fiscal year	1695
Total	2395

The following action was taken on these applications:

Recommended for membership	1494
Recommended for membership (special cases)	15
Deferred indefinitely	7
Deferred	11
Denied promotion	5
In regular course of procedure	863
Total	2395
Reinstatements and reconsiderations pending	18

Those recommended for membership were divided into the following grades:

Members	412
Promotion to Member	75
Associates	115
Promotion to Associate	2
Associate-Members	342
Promotion to Associate-Member	43
Juniors	505
Total	1494

The reinstatement of thirteen members was recommended to the Council.

Under B 16, it was recommended to the Council that the dues of seven members be permanently remitted.

Respectfully submitted,

Hosea Webster, *Chairman*,
James W. Nelson,
S. D. Collett,
W. C. Morris,
Nicholas S. Hill, Jr.
Membership Committee.

Report of House Committee

The report of the House Committee for last year referred to certain building additions and alterations, which made it necessary to hold the Annual President's Reception on the fifth floor of the Engineering Societies Building instead of in the Society's rooms. This function was very satisfactorily carried out, judging from the comments of members and guests who attended the reception, and no doubt future receptions can be held in the same manner and place, with equally good results.

The changes in the Board Room referred to in last year's report have been made, but it has been considered advisable to withhold redecorating this room and hall, or lobby, until the contractors for building changes have completed this work, on account of the dust which accumulates through the building. It is hoped that this work can be completed before the Annual Meeting in December 1917.

It has been found necessary to make certain extensive alterations in the working offices of the Society's quarters, with a view to providing more room and far better facilities for lighting, arrangement of desks for employees, intercommunication and acoustic properties. These changes are well under way and should be completed by October 1, 1917. The expense involved is about $6600, but no doubt will prove to be one of the best investments the Society ever made.

During the year the Society received as a gift from Miss Hoadley a most excellent oil portrait of Past-President J. C. Hoadley. This has been hung on the wall of one of the Society's rooms.

Of Past-Presidents' photos, that of Dr. D. S. Jacobus has

been received and added to the Society's most excellent collection.

Respectfully submitted,

Fredk. A. Scheffler, *Chairman*,
James W. Nelson,
Orrie P. Cummings,
H. O. Pond,
Maxwell W. Upson.
House Committee.

Report of the Committee on Constitution and By-Laws

The Committee on Constitution and By-Laws, at meetings held January 19, March 26, and April 16, 1917, discussed various proposed amendments and additions to the Constitution and By-Laws of the Society, and subsequently recommended changes to the Council. These amendments were approved by the Council on April 20, and were presented at the Spring Meeting in Cincinnati in May.

In accordance with C57, the amendments to the Constitution were published in the October issue of The Journal. They will be presented for discussion and final amendment at the forthcoming Annual Meeting and will subsequently be sent to all members entitled to vote, and the final vote of adoption will be closed on March 4, 1918.

Some of the changes in the Constitution necessitated changes in the By-Laws which have also been recommended to the Council and were approved on October 12, as well as new By-Laws for Professional Sections, Local Sections, etc.

The By-Laws governing Local Sections are the combined effort of about two years' work on the part of the Committee on Constitution and By-Laws and the Committee on Sections, and were framed to conform with all phases of the Local Sections' work to be found in different parts of the country, to afford the Sections every opportunity to carry on activities of local interest and at the same time to have their procedure in conformity with the Constitution and the By-Laws of the Society. These amendments are appended to this report.[1]

The changes in the By-Laws made necessary by the amendments to the Constitution and the new By-Laws, including those governing the Professional Sections, are also appended.

The Committee has also under consideration modifications to the By-Laws to provide for the decision of the Council to suspend the dues of members in active service for the period of the war and for six months after peace is declared, and also to exempt from dues a member reaching the age of seventy years, and who has paid dues for thirty-five years.

Respectfully submitted,

F. R. Hutton, *Chairman*,
Ira H. Woolson, *Secretary*,
James E. Sague,
George M. Basford,
Jesse M. Smith.

APPENDIX

Changes in the By-Laws Necessitated By Changes in the Constitution

The Committee on Constitution and By-Laws recommends that the By-Laws governing the Library Committee, the House Committee and the Research Committee be amended, and that new By-Laws governing the Public Relations Committee, the Standardization Committee and the Constitution and By-Laws Committee be provided, as follows:

Committee on Library

B 24 There shall be a Standing Committee on Library to consist of four Members and the Secretary of the Society. One of the four Members shall be appointed by the President before the first day of each calendar year to serve for four years.

It shall be the duty of the Committee to represent the Society on the Library Board of the United Engineering Society.

The Committee shall deliver to the Secretary before October 15 of each year a detailed report of its work for the preceding twelve months and also of the work which it recommends for the next fiscal year, with an estimate of the cost thereof.

House Committee

B 25 There shall be a Standing House Committee to consist of five persons who shall be Members, Associates, Associate-Members or Juniors. The term of office of one Member of the Committee shall expire at the end of each Annual Meeting. It shall be the duty of the House Committee to have the care, management and maintenance of the rooms of the Society and furnishings, the historical relics, the paintings, and objects of art, and to recommend to the Council suitable regulations for their care and use. At the end of each fiscal year the Committee shall deliver to the Secretary a detailed report of its work.

Research Committee

B 43 There shall be a Standing Research Committee to consist of five Members, Associates, Associate-Members or Juniors. The term of office of one member of the Committee shall expire at the end of each Annual Meeting.

(*a*) This Committee shall have supervision of such research or investigations as may be directed or approved by the Council; shall correspond and collaborate with committees of kindred technical, scientific or other societies; shall keep in touch with researches conducted in other countries, which are of value to the engineer, and shall report the same quarterly to the Council.

(*b*) The Committee will be expected to maintain a system of announcement of results of research and the trend of investigations in any field which will be of value to the engineering profession.

(*c*) Gifts or bequests to the Society for the conduct of research or investigation shall be expended under the direction of the Council, and shall be kept separate from other Society funds.

Public Relations Committee

B ? There shall be a Standing Public Relations Committee to consist of five persons who may be members in any grade. The term of office of one member of the Committee shall expire at the end of each Annual Meeting.

It shall be the duty of the Committee to consider and report to the Council its recommendations covering any matters which may be referred to it bearing upon the relations of the engineer as a man of science to the community in which he lives.

Committee on Standardization

B ? There shall be a Standing Standardization Committee to consist of five Members of the Society. The term of office of one member of the Committee shall expire at the end of each Annual Meeting. It shall be the duty of this Committee:

(*a*) To formulate and revise standards of principle, method or procedure, in engineering practice.

[1] Published in The Journal, November 1917, p. 940.

[illegible] To coöperate with committees of bodies of [illegible] or [illegible] of the Society, in the formula[illegible] [illegible] and to appoint under approval [illegible] committees of experts in specialized subjects [illegible] with them. The Chairman may represent the committee on standardization at any conferences.

To report to the Council with its recommendation any [illegible] standards for its approval, and when approved to [illegible] and recommend such standards to the members of the Society, and secure this publication in The Journal and Transactions of the Society.

Committee on Constitution and By-Laws

B ? The Committee on Constitution and By-Laws shall consist of five persons who shall be Members of the Society. The term of office of one member of the Committee shall expire at the end of each Annual Meeting.

It shall be the duty of the Committee to consider and report on all matters relating to the Constitution, By-Laws and Rules of the Society which shall be referred to it.

New By-Laws

It was recommended that the existing Rules 17 to 24 inclusive, defining the functions of Professional Sections and Geographical Groups, be changed to a By-Law, and that they be amended to read as follows:

Professional Sections

B ? (*a*) A professional Section of the Society shall consist of Honorary Members, Members, Associates, Associate-Members and Juniors of The American Society of Mechanical Engineers and of other persons to be designated Affiliates as hereinafter described.

(*b*) A Professional Section of The American Society of Mechanical Engineers may, with the approval of the Council, be organized for the consideration of any engineering, scientific, or professional topic, provided that a number satisfactory to the Council, of Members of The American Society of Mechanical Engineers, unite in making written request for such an organization. Such a section shall be designated as . . . Section of The American Society of Mechanical Engineers—the blank being filled by the topic specialized.

(*c*) The provisions of the Constitution, By-Laws and Rules of The American Society of Mechanical Engineers, and the precedents of the Society with respect to professional sessions for the discussion of papers, shall cover the procedure of the Professional Sections except that no meeting of a section shall be considered a meeting of the Society as a whole.

(*d*) For the convenient conduct of its professional affairs the section shall organize an Executive Committee of five members of the Society, under the general direction of the Council. Such officers as the section shall require must be selected from the membership of the Society. Other committees of the section shall be appointed by its Executive Committee.

(*e*) The Executive Committee of the section, subject to the approval of the Secretary of the Society, shall designate a Secretary of the section whose duties shall be those usually attaching to the Secretary of a professional section, and who shall also see that the discussions of papers are satisfactorily reported and transmitted to the Secretary of the Society.

(*f*) Expenditures for the purpose of a section chargeable to the Society must be authorized by the Secretary of the Society before they are incurred, and must be provided for in the budget approved by the Council. No liability otherwise incurred shall be binding on the Society. Any expenditure not so provided must be met by the section itself.

(*g*) Engineers and others not members of The American Society of Mechanical Engineers, but desiring to participate in the meetings of the section may enroll themselves as Affiliates as heretofore provided, with the approval of the Executive Committee of the section. Such Affiliates shall have the privilege of presenting papers and taking part in the discussions. They shall pay $5 per annum, which shall be due and payable in advance on October 1 of each year of their enrollment, and shall thereby be entitled to receive the regular issues of The Journal for a period covered by such subscription.

(*h*) The Council of The American Society of Mechanical Engineers may, at sixty days' notice, suspend or disband any section.

Quorum at Council Meetings

B ? The number of persons constituting a quorum of the Council shall be one-third of the number of members of the Council then in office.

Committee on the Washington Award

B ? The Committee on the Washington Award shall consist of two members appointed by the Council to serve for a term of two years. The term of office of one member of the Committee shall expire at the close of the Annual Meeting of the Society in each year. The appointment to fill a vacancy shall be made before January 1 in each year.

This Committee shall coöperate with the Western Society of Engineers in selecting the recipient of the Washington Award which is to be presented annually to an engineer who has contributed preëminent service in promoting the public good.

ROLL OF HONOR

At the October 12 meeting of the Council it was voted that a list of all the members of the Society now in active service be published and distributed at the Annual Meeting. This list will be prepared from the Honor Rolls published in The Journal from May to December inclusive, with such other names as may be sent in in time. The Publication Committee requests information regarding any members who have joined the armed forces of the country but whose names have not been listed as yet in the Roll of Honor. Such information if forwarded to the Secretary by November 30 will be included in the Annual Meeting pamphlet.

We have published in The Journal notices of 601 members from all parts of the Union who have notified us of their enlistment. A large proportion of members listed are commissioned in the Engineer Officers' Reserve Corps or in the Ordnance Department, Officers' Reserve Corps. The Aviation Section of the Signal Corps, and the Naval Reserve, are also well represented.

The following Roll of Honor supplements those already published, and also includes the Providence Engineering Society.

Alden, John L., Second Lieutenant, Ordnance Department, N. A.

Allen, Walter C., Major, Signal Corps, American Expeditionary Forces, France.

Armstrong, Henry C., Captain, Ordnance Department, United States Reserve.

Boardman, Albert J., Captain, Division American Ordnance Base Depot in France, Washington.

Boyd, F. F., Lieutenant, United States Naval Reserve Force.

Clark, W. Chas. M., Lieutenant, Naval Service, United States Navy Yard, Philadelphia.

Crawford, C. H., Captain, 302nd Engineers, Camp Upton, Yaphank.

Diemer, Major, Ordnance Department, United States Reserve.

Doll, William E., 35th Engineers, Camp Grant, Rockford, Ill.

Fell, Shelby G., First Lieutenant, Sanitary Corps, Port of Embarkation, Newport News, Va.
Fox, Rudolph H., First Lieutenant, Ordnance Department, Officers' Reserve Corps.

Gunby, F. M., Major, Quartermaster's Corps, United States Reserve.

Harris, George E., Reserve Officers' Training Camp, Fort Niagara, N. Y.
Hartwell, Arthur E., First Lieutenant, Engineer Sub-Depot, Camp Wheeler, Ga.

Kelly, William, Reserve Officers' Training Camp, Fortress Monroe, Va.
Kessler, A. G., Lieutenant, N. N. V., Navy Department, Bureau of Ordnance.
Kessler, Herbert J., First Lieutenant, Ordnance Department, Officers' Reserve Corps.
Kneass, Strickland, Jr., Sergeant, 332nd Infantry, Camp Sherman, Chillicothe, Ohio.

Laney, Thomas G., Second Lieutenant, Battalion E., 341st Field Artillery, Camp Funston, Kan.
Lea, Edward S., Major, Frankford Arsenal.

McGlone, R. G., Captain, 23rd Engineers, Camp Meade, Md.
Marshall, William C., Captain, Ordnance Department, U. S. R.
Misch, Arthur A., Lieutenant, Ordnance Department, United States Reserve.

Ogden, Nelson, Gun Division, Ordnance Department, Washington, D. C.

Parish, William F., Signal Corps, Equipment Division, Specification Department, Washington, D. C.
Parks, Burritt A., Captain, Engineer Officers' Reserve Corps.
Patton, Thomas A., First Lieutenant, Ordnance Department, United States Reserve.

Robinson, Parker M., First Lieutenant, Ordnance Department, Frankford Arsenal.
Rogers, John D., Captain, Railway Engineers.
Rogers, Theo. B., Second Lieutenant, Engineer Officers' Reserve Corps, 114th Engineers, Camp Beauregard, Alexandria, La.
Root, Virgil A., Captain, Ordnance Department, United States Reserve.

Swift, Harley L., First Lieutenant, Engineer Officers' Reserve Corps, 16th Engineers (Railway), American Expeditionary Forces, France.

Weber, John, Lieutenant, General Engineer Depot, U. S. A.
Welling, Lindsay H., Ordnance Detachment, Rock Island Arsenal, Ill.

Yoder, Thomas M., Captain, Ordnance Department, N. A., Watervliet Arsenal, N. Y.

Providence Engineering Society

The following members of the Providence Engineering Society, affiliated with our Society, are engaged in active military or naval service:

Major Franklin E. Edgecomb, United States Coast Artillery Corps.
Major John T. Keenan, United States Reserve Engineers' Corps.
Major Frank B. Gilbreth, United States Reserve Engineers' Corps.
Major Cyril L. D. Wells, United States Coast Artillery Corps.
Lieut. Lucian Minor, United States Navy.
Lieut. Edwin C. Bliss, United States Naval Reserve Force.
Capt. Norman D. MacLeod, 103d Regiment Field Artillery.
Capt. Leighton T. Bohl, United States Reserve, National Army.
Capt. N. V. S. Mumford, United States Reserve, Ordnance Department.
First Lieut. Frederick E. Cooper, Reserve Officer, Ordnance Dept.
Second Lieut. Valentine G. Libby, Reserve Officer, Engineers' Corps.
Sergt. Wallace Burton, 103d Regiment Field Artillery.
Sergt. C. K. Appleby, Coast Artillery Corps.
Sergt. Earl W. Taylor, Coast Artillery Corps.
Ralph S. Mohr, 103d Regiment Field Artillery.
Wm. McSweeney, Engineer Corps.
Anthony Caputi, Naval Reserve.
Lester W. Preston, Naval Reserve.
Ernest S. Fitz, School of Military Aeronautics.
Bicknell Hall, Jr., School of Military Aeronautics.
Robert N. Foote, School of Military Aeronautics.
Hugh Bain, Reserve Officers' Training Camp.
Howard H. Quinham, Reserve Officers' Training Camp.
Frederick E. Stockwell, Reserve Officers' Training Camp.
John V. Keily, National Army.
Ralph Now, National Army.

Fuel Conservation

To the Editor:

The following letter was received from Mr. H. A. Garfield of the Fuel Administration in Washington:

> Dear President Hollis:
>
> I wish you to know how much I appreciate the offer of assistance of the Engineering Societies in connection with the campaign for the conservation of fuel.
>
> As explained to you in conversation, President Wilson has charged Mr. Hoover and me with prosecuting a campaign looking to the conservation of food and fuel. We, in turn, are looking to the experts in their several fields for assistance. Already I have conferred with the officers of the Bureau of Mines and representatives of the Council of National Defense.
>
> I venture to suggest that an effective co-operating body be organized, so constituted as to furnish to this Administration expert advice and suggestions.
>
> Very truly yours,
>
> (*Signed*) H. A. Garfield, *Fuel Administrator.*

This letter refers to the national campaign for the conservation and use of fuel during the war. It has great possibilities for the future, after the war is over, when we may make a more permanent organization for the saving of waste, not only in fuel, but in everything. The engineers are naturally the experts on all subjects relating to fuel and to the industries, so that they must be prepared to take their share under any Government organization.

All members of our Society are urged to assist in the nation-wide campaign for conservation of fuel. They can do this in the power stations over which they have control by teaching the employes better methods, and by careful study of possibilities of saving.

Part of the success is a campaign of publicity. We have not yet waked up to the fact that only by sacrifice and saving can we serve our country best. Every engineer of our Society, and of other Societies as well, should be prepared to speak on saving, and they should offer themselves wherever the opportunity arrives. This is one form of service that may be extremely useful.

The members of The American Society of Mechanical Engineers are well fitted by technical knowledge to speak on coal conservation, and they ought to be ready to speak in such a way that the general public can understand. In the campaign of publicity, the fuel administration will consult the Bureau of Mines, and will strive to make all leaflets and posters sent out technically correct. Any member of our Society who is not drawn into the Army, and who desires to assist in fuel conservation, would do well to write Prof. O. P. Hood, of the Bureau of Mines, Washington, volunteering to serve in some way at home, especially in teaching how to use coal and wood with economy.

It may be that in some parts of the country their services will not be needed; at the same time we all ought to be ready to do our part wherever we are. Doubtless some method will be found for organizing a speaking campaign, whether under the Bureau of Mines, through the Chambers of Commerce, or directly by the Fuel Administratioon. Professor Hood will be able to supply information on the subject, and will let our members who volunteer for speaking know definitely where to apply. This war calls for sacrifice on every one's part, and for the present we must all be prepared to volunteer our services without pay; later, methods may be found to pay engineers who give all of their time to the home campaign for saving.

Yours very truly,

Ira N. Hollis, *President.*

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER JANUARY 10, 1918

Below is the list of candidates who have filed applications for membership since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate Member, those in the next class under Associate or Associate Member, those in the third class under Associate Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. **All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by January 10, 1918, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about February 15, 1918.**

The total of new applications since January 1 is 1633.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

Colorado

RIENKS, George W., Assistant Chief Engineer, Great Western Sugar Co., Denver

Connecticut

RYAN, E. F., Factory Superintendent, Remington Arms U. M. C. Co., Bridgeport

TOMLINSON, William R., 2nd Vice-President and Factory Manager, Billings & Spencer Co., Hartford

TRUAX, William H., Employment Manager, The Yale & Towne Mfg. Co., Stamford

WARDWELL, George W., Chief Draftsman, Norwalk Iron Works Co., South Norwalk

District of Columbia

KLONOWER, Arthur A., Mechanical Engineer, Bureau Yards & Docks, Washington

Florida

GREENE, Henry F., Assistant Manager, Coronet Phosphate Co., Plant City

Illinois

BACHMAN, Charles L., 1st Lieutenant, U. S. Engineers Reserve Corps, Chicago

MOWRY, Harry W., Standardization Engineer, Western Electric Co. Inc., Chicago

PEEBLES, James C., Assistant Professor, Armour Institute of Technology, Chicago

SCHOLES, D. R., Vice-President and General Superintendent, Illinois Malleable Iron Co., Chicago

WESTERBERG, Alfred E., Field Manager, Appraisal Work, Coates & Burchard Co., Chicago

Kansas

JOHNSON, Charles E., Engineer, The Diamond, Osage & Ajax Gasoline Cos., Kansas City

Maine

JACKSON, Lawrence B., Mechanical Engineer, The Texas Steamship Co., Bath

Massachusetts

BREKENFELD, Jacob C., Assistant Superintendent Shops, N. Y., N. H. & H. R. R., Readville

HINCKLEY, Frank C., State Inspector of Boilers and Examiner of Engines, The Commonwealth of Mass., Springfield

TOWNE, Joseph M., Vice-President, National Blank Book Co., Holyoke

WATERHOUSE, Ezra P., Envelope Manufacturer, Worcester Envelope Co., Worcester

Michigan

STEERE, Frank W., Vice President and General Manager, Steere Engineering Co., Detroit

New York

ACHESON, Edward G., President, Acheson Corp., New York

GRAY, James H., Metallurgical Engineer, New York

KEMBLE, Thomas S., Assistant Engineer, Motor Division, Curtiss Aeroplane & Motor Corp., Buffalo

LUKE, John D., Chief Draftsman and Tool Designer, Remington Typewriter Works, Ilion

MILLER, Samuel W., Proprietor, Rochester Welding Works, Rochester

RACHALS, Walter, Assistant Chief Engineer, United States Steel Corp., New York

SCHEIN, Alexander, Assistant Chief Engineer, The Sperry Gyroscope Co., Brooklyn

WEMYSS, Duncan, Superintendent Steel Factory, Library Bureau, Ilion

ZAMBONI, Lawrence, Consulting Mechanical Engineer, New York

Ohio

CARROLL, Emil J., Electrical Engineer, American Laundry Machinery Co., Norwood

NORMAN, Carl A., Professor Machine Design, Ohio State University, Columbus

Pennsylvania

BENNETT, William B., Production Engineer, Union Steel Casting Co., Pittsburgh

CANBY, W. P., Engineer of Tests, Parkersburg Iron Co., Parkersburg

DONLEY, William G., Engineer, The Barrett Co., Frankford, Philadelphia

MORGAN, James L., Resident Engineer, Bayer Steam Soot Blower Co. of St. Louis, Philadelphia

PATTERSON, Thomas S., Assistant Professor Mechanics, Pennsylvania State College, State College

Tennessee

WATERMAN, J. S., General Manager, William J. Oliver Mfg. Co., Knoxville

Australia

FORD, Artuhr S., Chief Designer, Commonwealth Small Arms Factory, Lithgow, New South Wales

Canada

BERLINER, Edgar M., Director, Berliner Gramophone Co., Ltd., Montreal

England

POYNOR, Frederick W., Chief Engineer, R. Martens & Co. Ltd., London, E. C.

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

Delaware

QUERISPEL, Fred J., Chief Draftsman, Electric Furnace Corp., Philadelphia

New York

BISHOP, Ernest W., Engineer, Manual Apparatus Div., Western Electric Co. Inc., New York

Ohio

RICHARDSON, Thomas B., Turbine Construction Foreman, General Electric Co., Cincinnati

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

California

DE FREMERY, DONALD, Structural Steel Inspector, California & Hawaiian Sugar Refining Co., San Francisco

Colorado

SELINDH, HERBERT S., Mechanical Engineer, Holly Sugar Corp., Swink

Georgia

FLEMING, WILLIAM P., JR., Assistant Engineer, J. S. Schofield's Sons Co., Macon

Illinois

KROEPLIN, WILLIAM A., Secretary, Sheet Metal & Conveyor Co., Chicago

Ohio

DAWSON, MAYNARD S., Draftsman, The Woodard Machine Co., Wooster

FOR CONSIDERATION AS JUNIOR

Connecticut

CARTMELL, NATHANIEL M., Industrial Engineer's Staff, Winchester Repeating Arms Co., New Haven
LAZARUS, GEORGE H., Department Engineer, Remington Armory, Bridgeport
PALATINE, RENARD L., Instructor, Continuation School, Waterbury
PORTER, RAYMOND E., Designer and Draftsman, The Lake Torpedo Boat Co., Bridgeport

Illinois

MINKEMA, WILLIAM H., Assistant to Production Manager, The Whitman & Barnes Mfg. Co., Chicago

Louisiana

GIACOMINO, JOSEPH L., Production Engineer, Fylton Bag & Cotton Mills, New Orleans

Maryland

SPICER, GEORGE W., Designing Draftsman, Bethlehem Steel Co., Sparrows Point

Massachusetts

FLEWELLING, MILTON F., JR., Chief Draftsman, Ashton Valve Co., Cambridge
GOULD, HAROLD L., Draftsman, Morgan Construction Co., Worcester

New York

BROWNELL, FREDERICK J., Engineer, Western Electric Co., New York
HENNINGSON, LOUIS A., Designer and Estimator, Maintenance Department, American Locomotive Co., Schenectady
ISENBERG, MARTENS H., Erecting Engineer, Combustion Engineering Corp., New York
MORSE, EVERETT R., 1st Lieutenant Ordnance Department, U. S. A., Ithaca
REBER, JAMES B., Superintendent, Columbian Rope Co., Auburn
RIXMANN, CHRISTIE, Installation Div., De La Vergne Machine Co., New York
SCHENKER, ABRAHAM W., Designer, Lawrance Aero Engine Corp., New York
YOUNGBLUTH, R. O., Managing Engineer, Architectural Dept., American Radiator Co., New York

Ohio

MILKEY, LESTER E., Field Engineer and Assistant Sales Manager, The Sandusky Foundry & Machine Co., Sandusky

Pennsylvania

CROWLEY, HENRY L., Production Engineer, No. 4 Shop, Bethlehem Steel Co., South Bethlehem
WIKAN, CORNEL, Designer, Pittsburgh Steel Products Co., Monessen

APPLICATIONS FOR CHANGE OF GRADING

PROMOTION FROM ASSOCIATE MEMBER

Massachusetts

COE, HARRY L., Vice-President, Harpham, Barnes, Stevenson & Coe, Boston

PROMOTION FROM JUNIOR

Illinois

BIGELOW, CARLE M., Chief Engineer, Cooley & Marvin Co., Chicago

Missouri

BECK, CHARLES E., District Sales Manager, De La Vergne Machine Co., Kansas City

New Jersey

SCHMIDT, FRANCIS W., Assistant Engineer, American Agricultural Chemical Co., Carteret

New York

TOWNSEND, ALBERT C., Associate with H. R. Geiger, New York

Ohio

RODGERS, HORACE P., District Sales Manager, Steam Equipment Mfg. Co., Cleveland

Rhode Island

HALL, JAMES A., Assistant Professor of Mechanical Engineering, Brown University, Providence

REINSTATEMENT AND PROMOTION FROM JUNIOR

New York

NOLDE, FRED, Chief Engineer and Manager, Ice Machine Dept., De La Vergne Machine Co., New York

NECROLOGY

GEORGE SMITH RIDER

George S. Rider was born in Providence, R. I., on May 4, 1858. Upon leaving college he served an apprenticeship with the Brown & Sharpe Manufacturing Co. in Providence, and then spent a number of years in their shops. Later he traveled abroad extensively, and upon his return he became connected with the Warner & Swasey Co. at the time of the construction of the Lick telescope.

Mr. Rider's next position was with the Cummer Engine Co., from which he resigned to become an instructor in drawing and machine work in the University School of Cleveland, where he remained for about twelve years.

During these years at the University School Mr. Rider also carried on a private business as a consulting engineer, which in later years developed into the firm of George S. Rider & Co., consulting and designing engineers, of Cleveland, Ohio. He was the senior member of this firm up to the time of his death—a period of about fifteen years, during which time he designed many large and important power and industrial plants in that part of the country.

He was a member of The Franklin Institute of Philadelphia, the Cleveland Engineering Society, and the Cleveland Chamber of Commerce.

Mr. Rider became a member of the Society in 1900. He died on September 11, 1917.

WILLIAM THOMPSON ILER, JR.

William T. Iler, Jr., was born in New York on June 28, 1892. He was educated in the public schools of the city and was graduated from the Stuyvesant High School. In June 1915 he received his degree in mechanical engineering from New York University.

During the summer of 1913 he worked under the Heights of Buildings Commission in New York as engineering drafts-

[illegible] served as rodman and as- [illegible] Department of Public Works, [illegible] York. He obtained his shop experience in the [illegible] H. W. [illegible] & Co., Bound Brook, N. J.

William T. Iler, Jr.

Later he became assistant junior engineer with Gunn, Richards & Co. in Utica, N. Y. At the time of his death he was holding the position of assistant manager of the Slocum, Avram & Slocum Laboratories, N. Y.

He became a Junior of the Society in 1916. He died on October 18, 1917.

GEORGE E. SCARFE

George E. Scarfe was born in London, England, in November, 1856. He received his education in the London grammar schools, and when still very young started to learn his trade by becoming a machinist's helper.

His bent was toward electrical science, and in 1890 he accepted a position as engineer with an electric lighting company in New York. He resigned in 1892 to become associated with the Western Electric Co., in whose employ he was sent to San Miguel, San Salvador, Central America, as assistant engineer of construction on an electric-light plant there. Subsequently Mr. Scarfe held the positions of chief engineer of the Towanda Electric Lighting Co., and construction engineer of the Warren Manufacturing Co., Sandusky, Ohio.

In 1900 he became associated with the Pacific Gas and Electric Co. in its Nevada division in charge of the power plant, and in 1904 became manager of the South Yuba Water Co. Mr. Scarfe's ability was evidenced not only in the immediate work of the company, but as a consulting engineer for the large gold-mining companies of that region.

After several years' connection with the Pacific Gas and Electric Co., Mr. Scarfe was appointed to the office of district superintendent, which position he held till April, 1916, resigning to enter the private practice of electric and mechanical engineering. He acted as consulting engineer for the Pacific Gas and Electric Co., Empire Mines Co., Pittsburgh Mines, South Eureka Mines, and a number of others.

He was an associate member of the American Institute of Electrical Engineers. He became a member of the Society in 1916. He died at his home in Nevada City on August 24, 1917.

SVERRE TRUMPY

Sverre Trumpy was born in Bergen, Norway, in January 1882. He was educated in a German preparatory school and received the degree of B.M.E. in 1903 from the Royal Technical University, Berlin.

During his college course, from 1899 to 1903, he served his apprenticeship with the Accumulatoren Fabrik Aktiengesellschaft, Hagen, Westphalia. Upon graduation he accepted the position of assistant superintendent of the municipal electric plant, Bergen, Norway. His next position was with the Fort Wayne Electric Works of the General Electric Co., Madison, Wis., as machinist. In 1904 he became associated with the Gisholt Machine Co. in Madison as draftsman, and in 1906 was made chief draftsman of the vertical boring-mill department. In 1911 he was placed in charge of the engineering department and the drafting room.

Mr. Trumpy became a member of the Society in 1913. He died at his home in Madison, October 17, 1917.

THOMAS C. WALKER

Thomas C. Walker was born in England in 1859. He was educated in the public schools there, and it was there also that he served his apprenticeship in machine work and tool making. He gained his shop experience with the Birmingham Small Arms Co.

For four years he was in charge of the machinery for the Carbon Mill in Colorado. He was also associated for about four years with the Denver & Rio Grande Railroad Co. At the time of his death he was president of the Walker Manufacturing Co., Denver, Col.

George E. Scarfe

He became a member of the Society in 1891. He died on February 13, 1917.

AMONG THE SECTIONS

Four signal events this year will go down in the history of the Sections as marked developments in this activity. The first is the new By-Laws which were approved at the Council meeting in October and published in the November issue of The Journal. The second is the Sections Session to be held at the forthcoming Annual Meeting. The third is the development of the first State Section—Connecticut—with five Branches, at Bridgeport, Hartford, Meriden, New Haven and Waterbury. The fourth innovation is the holding of meetings of the Committee on Sections in the various cities where Sections are established; such meetings have recently been held with marked success at St. Louis, Milwaukee, Chicago and Detroit.

The Sections Session, which will be held on Thursday morning of the convention, represents the first time that the Session of a general meeting has been given over to the discussion of Sections' matters. This Session will be in charge of the Committee on Sections and Mr. D. Robert Yarnall will preside. Three-minute talks will be given by delegates from each of the Sections, followed by general discussion.

The Committee on Meetings and the Committee on Sections decided to hold this Session to discuss ways and means of increasing the coöperation and cohesion of the Section elements at this period of the Sections' development. There are many vital topics to be considered and it is hoped that the discussion will be fruitful and will guide this activity of the Society into the way of accomplishing big things, not only for the engineering profession but for the public at large.

The phases of the Sections' work are manifold. In each center in which Sections are established, opportunities for service arise at every turn. The new Sections' By-Laws govern the activities of each Section only to the extent of ensuring that its procedure is in conformity with the Constitution of the Society; they leave the Section free to carry out the details of its coöperative work with other societies' sections and with the local organizations and the public.

In addition to the talks they will give at the Sections' Session, the delegates will come into personal contact with the Council and with the management of the Society at the convention, and will thus have opportunity for familiarizing themselves particularly with the parent Society's attitude towards its branch organizations. This is an important essential, for the individual Section members should understand clearly in just what relation they stand to the parent Society, and by such understanding they will be able to derive the greatest benefit for themselves and to perform the most good for their fellow Section members and for the membership of the Society at large.

Other Section activities at the Annual Meeting will include "experience meetings" held by delegates, in which each delegate will outline what his Section has accomplished during the year; the Sections' Luncheon, which will be held this year at the Engineers' Club, 32 West 40th Street, New York, on Tuesday, December 4, at 12:30 p.m., and the usual informal meetings of Sections' delegates with the Committee on Sections.

THE PRESIDENT'S TRIP

In the following letter to Mr. Rice, Dr. Hollis conveys the impressions of his recent trip to the Pacific Coast Sections. The President was very much struck by the spirit of self-sacrifice he found everywhere among the engineers—everyone wanting to serve his country.

My Dear Mr. Rice:

I left Washington on the evening of October 15 and had dinner in St. Louis on the following evening with the Executive Committee of our society in that center.

Then I went to El Paso, arriving on the afternoon of October 18, and made an address to the Southwestern Society of Engineers during the evening, on the subject of The Engineer and the War. There were present all of the members who could get to El Paso, and a general audience of citizens. On the nineteenth the entire membership made an inspection of the engineers' camp on the Rio Grande, not far from El Paso, and in the evening there was a dinner.

I arrived in Los Angeles in the very early morning of the twenty-first and there made two addresses. The first was before the engineers of Southern California, and about 250 were present, representing all of the engineering societies; the subject was again The Engineer and the War. At Throop Institute I addressed the entire body of students. This institute is in Pasadena and will become the same kind of institution that the Rensselaer Polytechnic Institute at Troy is.

I reached San Francisco on the evening of the twenty-fourth and met the engineers representing all societies at dinner on the following evening. About 250 were present, and the subject was The Moral Influence of Engineering Efficiency. On the twenty-sixth I visited the University of California, but did not meet the students as I went there to see the instruction in aviation. On the twenty-eighth I met a number of the members of our society in Portland, Ore., and had dinner with them.

On the evening of the twenty-ninth I had dinner in Seattle with all of the societies represented in that city. There were something under 100 present.

On the thirty-first I left for home on the Canadian Pacific and arrived on Monday, November 5.

The strong impression I received from this trip was the spirit of self-sacrifice amongst the engineers, every one of whom wants to serve the country in some capacity. In Southern California and Arizona alone 250 engineers have already gone into the Engineer Corps of the Army, and there was not a single discordant note in connection with the requests for opportunities to serve.

The only symptom that was at all disturbing to an American citizen was the evident lack of information on the meaning of this war. While all were willing to serve, a great many seemed slow to understand the sacrifice that this great struggle is going to demand of all of us.

Another thing that impressed me was the value to the engineering societies of more frequent communication with the West. I believe the four engineering societies ought to unite to provide just such visits as this every year to ensure the Coast being kept in complete touch with what we all want to do.

(*Signed*) Ira N. Hollis.

On his way out to the Coast Dr. Hollis attended a conference at the U. S. Chamber of Commerce, at Washington, on the coal question, and offered the services of the Engineering Council in connection with the campaign for the conservation of fuel. During this conference he, Professor Breckenridge and Mr. Lieb were added to the Chamber of Commerce Committee on Fuel.

SECTIONS' COMMITTEE VISIT

Committee on Sections at St. Louis, Milwaukee, Chicago and Detroit, October 22 to 25

THE members of the Committee on Sections feel that a great deal was accomplished by their recent trip to four of the Sections located in the Middle West, and the opinions which have been expressed by the officers of the respective Sections visited are indicative of their appreciation of the recognition shown them.

The following members of the Sections Committee made the trip: D. Robert Yarnall, *Chairman*, L. C. Marburg, Prof. Walter Rautenstrauch, Dean Charles Russ Richards. Ernest Hartford, Secretary to the Sections Committee, accompanied the party. The only member of the Committee unable to be present was Major E. H. Whitlock, whose work for the Government made it impossible for him to obtain a leave of absence.

The party arrived at St. Louis on October 22 and was met at the station by the Executive Committee of the St. Louis Section. A visit was made to the Ashley Street Power Station of the Union Electric Light and Power Co., where the operations involving the change from the old reciprocating units to the new 20,000 kw. turbines were demonstrated to the party.

The St. Louis members turned out to the number of over sixty to the supper which was followed by a paper on the developments at the Ashley Street Power Station, presented by Mr. John Hunter, Vice-President-elect. Then the visitors each spoke outlining their work in the interest of the Sections, the manner in which Sections may coöperate in making THE JOURNAL the leading publication of its kind and suggestions for coöperation between Sections and the vital work of the Research Committee.

On the following day the Committee reached Milwaukee, visited the plant of the Allis Chalmers Company, and later had supper and discussed section matters with members of the Milwaukee Section. At this meeting a movement was started to develop the membership and scope of the Milwaukee Engineering Society with which the A.S.M.E. Section is affiliated.

The Chicago Section was next visited and a supper meeting held at the Hotel La Salle, at which were present about twenty-five of the active members of the Chicago Section. At this meeting plans were laid in the direction of securing close coöperation of the A.S.M.E. Section with the Western Society of Engineers, the Chicago Engineers' Club and the other engineering organizations of the city.

On the fourth successive day the Committee were guests of a Section, this time the A.S.M.E. organization in Detroit. The local committee met the visitors at the train and conducted them during the day to a number of plants where a more intimate acquaintance was obtained with the local conditions and the individual leaders in the engineering profession in Detroit. In the evening a dinner was held at the Chamber of Commerce, about sixty being present. Professor Rautenstrauch presented a paper on the Relation of the Engineer to Finance, and Dean Richards told of the research work being carried on at the Experiment Station of the University of Illinois. The meeting voted unanimously to invite the Society to hold its 1919 Spring Meeting at Detroit. All the week's activities were productive of much that should materially enhance the value of membership to those located not only in the four Sections visited, but to the entire Society.

D. ROBERT YARNALL,
Chairman, Committee on Sections.

CONNECTICUT SECTION INITIAL MEETING

THE first meeting held under the auspices of the new Connecticut Section was held at New Haven on November 14. There were two sessions, both devoted to the subject of fuel conservation. The first began at 2.30 p. m. at Lampson Lyceum, Yale University, with Mr. Henry B. Sargent in the chair. Over 150 were in attendance.

At the outset of the meeting, Mr. Sargent outlined the development which led to the formation of the Connecticut Section with its five branches at Bridgeport, Hartford, Meriden, New Haven and Waterbury.

Prof. L. P. Breckenridge presented the first paper on The Problem of Coal Conservation. He outlined the necessity of coal for heat, light and power, and by means of a series of lantern slides gave some very interesting data relative to the production of coal throughout the world, and also, in more detail, the production in the several states of this country. The distribution of coal by rail and water were shown generally to be the determining factors in the choice of coal used. Charts showed the percentage of coal used (*a*) by states, (*b*) by industries, commerce, in homes and for making steam, (*c*) per capita for several states, and (*d*) in relation to manufactured products.

The latest available data on coal production and consumption is for the years 1914 and 1915. In 1914 of the 1,800,000,000 tons produced throughout the world, about 600,000,000 came from the United States. Great Britain ranked second and Germany third. About one-sixth of the coal produced in the United States is anthracite, but the statistics show that since 1880 the production of hard coal has never reached 100,000,000 tons. During the same period the production of bituminous coal has advanced from 50,000,000 to probably over 600,000,000 tons this year. The conclusion drawn by the speaker was that we would have to learn to burn bituminous coal in our homes.

The total production of coal in the United States from 1906 to 1915 was 4,918,717,285 tons. Of this, Pennsylvania produced all of the anthracite and a large portion of the bituminous. West Virginia, Illinois, Ohio, Kentucky and Indiana ranked next in the order given in the production of bituminous coal. In 1915, Pennsylvania used more anthracite than any other state, New York ranking next, the New England States third. Three million tons were exported.

The railroads used 122,000,000 tons of bituminous coal in 1915, and the use by states was, Pennsylvania most, and, in their order, Illinois, Ohio, the New England States, and New York. New York is the only state which used more anthracite than bituminous.

The use of coal per capita in the Pacific States is 0.35 tons;

in New York, New Jersey and Pennsylvania, 6.52 tons; in Ohio, Indiana, Illinois and Michigan, 5.31 tons; and in the New England States, 4.85 tons.

Professor Breckenridge's paper was discussed by Professors Seward, Perry, and Barker, Messrs. R. J. S. Pigott and A. J. German. Mr. T. W. Russell, fuel administrator for Connecticut, also participated.

The following suggestion to save fuel in Connecticut was made by Professor Breckenridge and adopted by vote of the meeting:

Voted, That the Connecticut Section of the A.S.M.E. instruct the chairmen of its several branches to name a committee on fuel saving for their respective localities.

After a series of motion pictures, dinner was served at the Yale Dining Club, at six o'clock.

EVENING SESSION

The evening session was held at Mason Laboratory, Sheffield Scientific School, with Mr. J. Arnold Norcross in the chair.

Mr. O. P. Hood, mechanical engineer of the Bureau of Mines, Washington, D. C., described briefly the scope of the Bureau's work, but his paper generally covered the subject of Fuel Conservation by the Bureau of Mines.

Mr. Hood said that under normal conditions the Government buys over $8,000,000 worth of coal annually. The Bureau has been making war on waste for years and has tried to get people to believe what they knew to be so. The Bureau has believed that educational methods were, in the long run, the sane methods by which to accomplish fuel conservation, but under the present conditions it is necessary that power also be used to compel saving—and at the same time the educational campaign must be speeded up and carried on on a magnitude never before attempted. In view of the fact that only about 20 per cent of the coal mined is used for domestic purposes, whereas 63 per ceut is used in the production of power, it is through those persons engaged in the latter occupation that the greatest saving can be most easily secured.

The 20 per cent used for domestic purposes is handled by about 20,000,000 persons and the possible saving would be about 10 per cent, so that it would be an expensive proposition to attempt to reach this enormous group to effect a net saving of 2 per cent of the coal mined. On the other hand, the 63 per cent used for power purposes passes over the shovels of not over a quarter of a million firemen, so that it is in this direction the first drive for conservation should be made. Fuel economy is an art and must be taught to the man at the furnace.

The coal recently mined has shown by analysis from 14 to 15 per cent ash, as against about 8 per cent normally, showing that the increased production of coal is really an increase in ash. One of the prominent central-station operators recently stated that this additional ash has cost his plant an additional 20 per cent to secure the same production. This faulty condition likewise increases the number of coal cars that are required to transport this additional ash.

In its experiments the Bureau has developed that it is feasible to burn soft coal for heating purposes and obtain practically the same results as are secured by the use of hard coal.

Mr. Hood pointed out that investigation in the conservation of fuel soon unearths the many fallacies that are in circulation. The engineers have the correct technical data at hand to further consistent conservation of fuel, and the Bureau of Mines is coöperating with the engineering societies and other organizations in order to give such organizations the benefit of its service in having facts correctly stated before they are disseminated.

Mr. Hood suggested that considerable data of value were contained in the Bureau of Mines technical papers Nos. 80, 97, 137. He also called attention to a pamphlet about to be issued of interest to designers of boilers. This is being prepared by Henry Kreisinger, Mem.Am.Soc.M.E.

The paper was discussed by Prof. E. H. Lockwood, Mr. Bromley, associate editor of *Power*; Mr. F. O. Wells, and Professor Breckenridge.

The meeting closed with a very inspiring address by President Ira N. Hollis on the part the engineer is destined to play in the service to mankind in the twentieth century. The audience was much impressed by the stirring words of Dr. Hollis.

SECTIONS REPORTS

BALTIMORE

November 7. The first meeting of the season was held at the Engineers' Club and the following discussions were presented: Evaporators, by William L. DeBaufre, Mem.Am.Soc.M.E., mechanical engineer, U. S. Naval Engineering Experiment Station, and Considerations in Municipal Ownership, by Prof. A. G. Christie, Mem.Am.Soc.M.E., Johns Hopkins University.

With the aid of lantern slides, Mr. DeBaufre first described simple evaporators and multiple-effect evaporators. He said that experiments at the Naval Experiment Station had demonstrated that increased efficiency could be secured by reducing the amount of tube surface in former standard types of evaporators, and that the rate of heat transfer had been thereby increased from 250 B.t.u. per sq. ft. per degree difference in temperature per hour to a new rate of 900 to 1000 B.t.u. Methods of handling had also been developed which obviated the necessity of frequent cleaning to remove scale.

Mr. DeBaufre next showed a new form of evaporator he had developed and with which the efficiency of a triple effect could be obtained in a single effect. In this new evaporator a portion of the vapor leaving the evaporator at low pressure is carried to a nozzle-type ejector which receives live steam through a nozzle. The low-pressure vapor is caught up by the high-velocity steam from the nozzle and forced into a diffuser tube in which it is compressed to the higher pressure, then led back into the evaporator jackets where its latent heat is available for further evaporation. Tests were presented by the speaker showing the efficiency of the apparatus, and diagrams were also shown which illustrated graphically where the gains occurred.

In the discussion that followed, one of the speakers pointed out that this system with its high efficiency should prove of value to power-plant engineers in view of the increasing tendency toward using distilled water for boiler feed.

Professor Christie compared experiences in municipal ownership of public utilities of cities in Canada and in the United States and outlined the conditions that have tended to make the Canadian experiences successful and the American ventures generally failures. Emphasis was laid on the need of absolute separation of the utility from politics and of placing its control under a single trained executive, preferably an engineer. The financial problems of municipal ownership were outlined and discussed. The final conclusion was that political conditions at present existing in the United States did not appear to be favorable to the adoption of municipal control of utilities. Private ownership under close supervision of public utility commissions seemed to be the best solution of the problem.

A. G. Christie,
Section Secretary.

BUFFALO

October 17. Scientific Research was the subject of a discussion by Dr. C. E. K. Mees, director of the research laboratory of the Eastman Kodak Co., at a meeting of the society.

Dr. Mees [illegible] that the Geniuses who have accomplished so [illegible] of scientific research are not geniuses but [illegible] who accomplish much because they [illegible] have the laboratory organizations. He [illegible] that great scientific discoveries are simply a matter of [illegible] hard work and luck, and that it is just as possible to speed [illegible] work as other kinds. The more men at work and the better the organization of the laboratory, the more work will be accomplished. Today is the day of standards, classifications, grades, brands and comparative analytical tests, he said, and tomorrow will bring, with its still higher standards and more exacting tests, synonyms for tremendously accelerated competition.

Dr. Mees illustrated his talk with stereoptican views of modern laboratory methods and equipment.

The Automotive Section of the Engineering Society of Buffalo held a very interesting meeting on October 24, at which Mr. Otto M. Burkhardt, mathematical research engineer of the Pierce-Arrow Motor Car Co., read a paper on Crankshaft Design. Discussion followed, in which David Fergusson and Ernest Harris, of the Pierce Company, and Forest E. Cardullo and Charles M. Manley of the Curtiss Company took part. In the course of his discussion Mr. Burkhardt drew the following striking parallel:

"Three groups of scientists are remarkably interested in one and the same problem, i.e., the problem of balancing.

The economist is seeking—The balance of trade.

The statesman is eagerly watching—The balance of power.

And last but not least, the engineer is developing balanced crankshafts.

(1) If balance weights are attached to a 3 or 4-bearing 6-throw crankshaft, its running at high speed should improve remarkably because considerable centrifugal forces and subsequent transverse deflections are eliminated.

(2) It is an easy matter to attach weights to a 7-bearing 6-throw crankshaft. This will not improve its running because there is practically no transverse deflection that could be eliminated, and the main bearings are less favorably loaded.

(3) A 3 or 4-bearing 6-throw crankshaft if properly balanced will not be much lighter (if at all) than a 7-bearing shaft.

(4) In the case of a 3 and a 4-bearing crankshaft, an intense torque occurs in the crankpin, a phenomenon which does not pertain to the 7-bearing type of crankshaft.

The subject proved very timely and interesting and the meeting was well attended.

Louis J. Foley,
Assistant to Section Secretary.

CONNECTICUT

November 14.—The first meeting held under the auspices of the new Connecticut Section was held in New Haven on November 14. A full account of this meeting appears on page 1022.

Henry B. Sargent,
State Section Chairman.

CINCINNATI

October 18. The Research Laboratory Applied to Industry was the subject of an address by F. O. Clements at an interesting meeting of the Section. The speaker described how for some years a group of manufacturers of Dayton have been looking forward to the building of a number of factories surrounding a research laboratory that would be common to all of these factories. While some of the factories were being erected, war was declared and the purposes for which these factories were to be used were changed. One of the factories was turned over to the Dayton-Wright Airplane Co., although it had originally been intended for another purpose. The research laboratory had been intended for the study of problems connected with industry, and its purposes were somewhat modified by the declaration of war. However, its general organization had been pretty carefully thought out, and a laboratory was organized about six months ago. It contains a group of enthusiastic young chemists and engineers, carefully selected. The speaker mentioned some of the problems that had come up for solution and the progress made toward their solution. Naturally, many of the problems that are being studied are of a secret nature, and cannot be mentioned, but the possibilities of such a research laboratory were discussed at some length. The speaker paid a tribute to the general spirit of coöperation which prevails in the city of Dayton and which made such a research laboratory possible.

John T. Faig,
Section Secretary.

ERIE

November 13. The Engineers Society of Northwestern Pennsylvania and the Local Section of the Society held a joint meeting at the Erie Public Library, under the auspices of the Local Section of the Am.Soc.M.E. An illustrated lecture was delivered by H. G. Barnhurst, chief engineer of the Fuller Engineering Co., Allentown, Pa., on Pulverized Coal and Its Future. The subject proved to be of considerable interest, as the present high cost of petroleum has boosted the price of fuel oil to a point that makes discussion of available substitutes of interest to all engineers. Mr. Barnhurst is unusually qualified to speak on this subject, as he has been closely following the matter for some years, and has supervised the installation of a number of large plants.

M. W. Sherwood,
Section Vice-Chairman.

NEW YORK

November 13. The November meeting of the Section was preceded by a buffet luncheon at which over 80 were present. The Acquaintanceship Committee took special pains to welcome new members and the occasion was made very enjoyable for all present.

Mr. Maxwell W. Upson presented the paper of the evening on "Concrete Piling." Mr. Upson spoke at the outset on some of the problems involved in overcoming the difficulties met with in supplying special equipment of this character. He then gave a detailed, illustrated description of the Raymond concrete pile, a new development which has never been used to any commercial extent before. This pile is a composite pile, the lower part being of wood and the upper of concrete. The special advantage of this pile construction is that it overcomes two of the problems always inherent to the composite pile. The first is to secure a satisfactory joint between the concrete and the wood, and the other is to maintain alignment between the two parts.

The speaker also touched on the advantage of this kind of pile due to the ease of transportation of the wooden part. At this time it is impossible to transport long wooden piles from one section of the country to another.

Herman Greul,
Section Committee Member.

PHILADELPHIA

October 16. A most important and successful meeting was held by the Philadelphia Section in conjunction with the Engineers' Club at Witherspoon Hall. Homer, L. Ferguson, president and manager of The Newport News Shipbuilding & Dry Dock Co., presented the timely and interesting subject of The War's Effect on Merchant Shipbuilding. Mr. Ferguson outlined the effect of the submarine menace, and called attention to the necessity for action on the part of the United States Government. He pointed out the difficulties involved in building ships due to the scarcity of labor, and particularly to the scarcity of that kind necessary in the shipbuilding trades. The war would be won, he said, if America would only provide sufficient shipping facilities to properly transport and supply our armies on the other side. A number of new shipbuilding concerns have sprung up to meet the great demand and he expressed it as his belief that many of the leaders in these enterprises do not appreciate the tremendous difficulties involved in this line of work. The high-handed action of some of the labor unions in limiting the number of apprentices and production at this time he considered greatly to be regretted.

John P. Mudd,
Section Secretary.

PROVIDENCE

November 9. Several meetings of note have been held during the past month, among which might be mentioned that of the

Efficiency Section at which Chester T. Morey, assistant superintendent of the Rhode Island Tool Company, read a paper on the Handling and Moving of Material. He discussed the question of incoming and outgoing material and its arrangement, control and transportation within the shop.

On Tuesday evening, November 13, a paper was read on Some Steels used in Machine Construction, by Chester B. Sadler, of the Rhode Island Tool Company. Mr. Sadler touched on the composition, physical properties, heat treatment and metallography of these steels.

The regular November meeting of the Providence Engineering Society was held on Tuesday evening, November 20, Chester T. Lucas, associate editor of *Machinery*, being the speaker of the evening. Mr. Lucas showed a moving picture film of the Machining of a 9.2-in. High-Explosive Shell furnished by *Machinery* and gave a talk on the manufacture of artillery ammunition.

James A. Hall,
Correspondent.

SAN FRANCISCO

October 25. The activities of this Section so far have been confined to the dinner tendered to President Hollis on the occasion of his recent visit to the Coast. This meeting took the form of a joint meeting of the local branches of the national engineering societies, each of the societies being represented by a speaker.

Prof. Harris J. Ryan, of Leland Stanford Jr. University, spoke on behalf of the American Institute of Electrical Engineers. Prof. C. D. Marks, of Stanford University, represented the American Society of Civil Engineers. Prof. Andrew C. Lawson, of the University of California, spoke for the American Institute of Mining Engineers, and Dr. L. H. Duschak, of the U. S. Bureau of Mines, represented the American Chemical Society. Prof. B. F. Raber, chairman of the San Francisco Section, presided at the meeting, and the guest of honor was introduced by Geo. W. Dickie, Vice-Pres.Am.Soc.M.E., with whom Dr. Hollis had been associated at the time he was naval inspector at the Union Iron Works, San Francisco.

The general subject discussed during the evening was the relation of engineering to the war, each speaker taking up the particular branch of engineering represented by his society.

The event of the evening was a stirring address by President Hollis on the subject of The Moral Influence of Engineering and Efficiency.

C. H. Delany,
Section Secretary.

ST. LOUIS

October 16. The visit of Dr. Ira N. Hollis, president Am.Soc. M. E., was made the occasion of a dinner reception at the Missouri Athletic Club. Owing to the fact that the president's stay in St. Louis was limited to a few hours, it was impossible to arrange a meeting of the Section, but the time was spent in talking over the affairs of the Society with the executive committee.

The members of the executive committee were greatly impressed with the fact that Dr. Hollis's policy throughout the year has been first and foremost one of service to the engineering profession. Surely there could be no more effective results obtained by the president of such an organization as ours than the adherence to the idea that everyone in the organization is to do his part toward being of some real service to his fellow engineers.

October 22. On this evening, at the American Hotel Annex, the St. Louis Section held a joint meeting with the National Committee on Sections. The meeting was preceded by a dinner, at which were seated seventy-five members of the Section and guests. Mr. R. L. Radcliffe, chairman of the Local Section, introduced Mr. D. Robert Yarnall, chairman of the National Committee on Sections, asking him to preside during the meeting. Very interesting and helpful talks were made by the different members of the visiting committee, whose ideas with reference to the management and activities of the Local Section were received with a great deal of interest and will prove of great value.

Mr. John Hunter, Mem.Am.Soc.M.E., chief engineer of power plants of the Union Electric & Power Co., delivered an illustrated lecture upon the subject The Development and Operation of a Large Power Station. Mr. Hunter took the Ashley Street Plant of his company as illustrative of his lecture, and showed during the course of the evening seventy stereopticon views of the growth and development of this great station. The audience of technical men was deeply interested in what Mr. Hunter had to say, and the explicit manner in which he demonstrated his subject.

The chairman of the Committee on Sections congratulated the Local Section on the nomination of Mr. Hunter to vice-presidency in the Society.

E. H. Tenney,
Section Secretary.

STUDENT BRANCHES

Student Branch Conference

As has been the custom for the past few years there will be a Conference of Student Branch representatives held during the Annual Meeting. Each of the forty-five Branches is invited to send a delegate to attend this Conference, which will take place on the afternoon of Wednesday, December 5, at four-thirty o'clock.

This Month's Reports

BUCKNELL UNIVERSITY

November 5. L. W. Sipley gave an interesting talk on Steam Turbines. Prof. Frank E. Burpee, Mem.Am.Soc.M.E., expressed his regret that the usual custom of the University's tours of inspection of the different plants would probably not be carried out this year as many of the plants have been closed to visitors.

H. R. Pars,
Branch Secretary.

CARNEGIE INSTITUTE OF TECHNOLOGY

November 7. There was a large attendance at this regular meeting, at which it was announced that practically every junior and senior student in mechanical engineering had joined the Society this year. Following the regular business session a talk on central-power-station operation was given by Mr. J. C. Hobbs, Mem.Am.Soc.M.E.

Mr. Hobbs first spoke on modern automatic stoking and described in detail the very efficient devices at the Detroit Edison Co. for burning all the combustible material in the refuse. These devices consist of grinders which carry out the refuse and prevent clinkers from being formed. He laid special stress on the construction of firebrick walls to take care of unequal expansion on opposite sides.

Mr. Hobbs gave a brief description of turbines, stating that the best practice in starting turbines, also in opening steam valves into large pipes, is to open with a shock, then cut off again almost immediately and come on gradually. This is to prevent the steam from floating in on top in a cloud, and causing unequal expansion to the top and bottom of the turbine casing and the pipes.

The speaker did not think that dry pipes on boilers were practical; in fact he said he had obtained better results by removing the dry pipes from the boilers. He also gave some ideas on determining the most efficient piping.

The talk was followed by a general discussion, and after a short social session, during which smokes and refreshments were served, the meeting adjourned.

G. R. Brandin,
Branch Secretary.

UNIVERSITY OF MISSOURI

The officers elected at the November 8 meeting of the Branch were: Honorary Chairman, H. Wade Hibbard, Chairman, L. N.

[illegible] J. W. Baldwin, Secretary [illegible] H. K. King [illegible] Committee, H. Wade Hibbard [illegible] E. R. Wharton, William Copper, M. M. [illegible]

[illegible] by the Honorary Chairman on the [illegible] National Society and the relations to it and the [illegible] a student branch, also by Prof. [illegible] Mem.Am.Soc.M.E., upon his summer work in [illegible] factory about to be taken over [illegible]. At a later meeting the Honorary Chairman [illegible] upon his work this summer for the War [illegible] Washington, D. C., as an organization, manage[illegible] production engineer in the laying out of organization [illegible] plant for expanding departments expending $[illegible],000,000, according to present appropriations.

The School of Engineering is engaged in a thoroughly patriotic service in infusing into the students an intensity of purpose in preparing for their later engineering work in the Army or munitions plants; to this the students are heartily responding. The Honorary Chairman never knew of such enthusiastic and intense study as is now being given to the various courses. The men almost feel that they are in uniforms and serving their country. Forty-seven members of the University faculty are in uniform and drilling three times a week under Captain Craigie of the U. S. Army, a course specifically authorized by Act of Congress in a university where the Government has authorized a Reserve Officers Training Corps. Six hundred students are in the Corps also. The Faculty Company will shortly be in target practice on the rifle range, will be taken out among the hills for map plotting, and next summer will go into camp in the Ozark Mountains, under Captain Craigie. The quota of the University in Columbia and Boone County was made for the Liberty Loan, the faculty alone subscribing about $50,000. The faculty and students are giving $10,000 for the Army Y. M. C. A. in the $35,000,000 campaign.

H. Wade Hibbard,
Honorary Chairman.

NEW YORK UNIVERSITY

November 4. Ernest Hartford, Secretary to the Committee on Student Branches, addressed the members at the first meeting of the Branch for the season. He explained the privileges of the student-members, the benefits to be derived from the Society and also announced the meetings that the Am.Soc.M.E. is to hold and the topics to be discussed. Professor Houghton made a few suggestions concerning the organization of this Branch.

It was decided to hold one big meeting each month on the third Friday of the month, at the Engineering Societies Building at 8.00 p. m. Prominent men in the engineering world will head the program of each meeting, with addresses and illustrated lectures. It was announced that the first meeting would be held November 23, and everybody would be welcome.

Frederick Groepler,
Branch Secretary.

POLYTECHNIC INSTITUTE OF BROOKLYN

November 6. The first meeting of the Branch for the season resulted in the election of Charles L. Schweizer as chairman, to replace Frederick Bromm, who has been called into service, and William Sumner as vice-chairman. The regular business was followed by a lecture on Atoms, Electrons and the Constitution of Matter, delivered by Dr. A. A. Adler, Mem.Am.Soc.M.E. Interesting topics of Dr. Adler's talk were the size of the electron, the composition of X-rays and the heat waves of the sun.

Nathan N. Wolport,
Branch Secretary.

RENNSELAER POLYTECHNIC INSTITUTE

November 7. The third regular meeting of the Branch was held on this date at 7:45 p. m.

Mr. J. M. Dewey spoke upon the present plans for equipping the army with field laundry machinery. He thoroughly explained the problems met with in designing this machinery for motor-truck units, train units, and base units, and the methods pursued in overcoming each of these problems.

Mr. G. H. Carragan described the manufacture of paper. His talk was in the nature of a supplement to the recent trip the Branch made through the plant of the West Virginia Pulp and Paper Co., at Mechanicville, N. Y. He gave the history of the development of the industry, a summation of the various kinds of fibers used in paper making and a review of the different grades of paper and the processes followed in making each grade.

R. A. Marriott,
Branch Secretary.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing housé in these matters.

In forwarding applications, stamps should be enclosed for transmittal to advertisers; applications of non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society.

GOVERNMENT POSITIONS

The Society has been asked to make suggestions of men for the following positions with the Government. Non-members possessing the necessary qualifications may avail themselves of these notices by enclosing with their reply a personal introduction to the Secretary.

SEVERAL ENGINEERS who have had considerable experience in the design of machines and machine tools, which would enable them to comprehend quickly questions involved in the designs of field-artillery material. 2426.

THE MOTOR SECTION of the Ordnance Department is charged with the procurement of tractors and trucks for hauling artillery and ammunition, including maintenance, inspection and training of drivers, also similar work in connection with armored cars and armored tanks. The principal duties of this section, however, will be the maintenance and upkeep of these vehicles in the field. 2427.

A NUMBER OF MEN with milling, mechanical or electrical engineering training and experience, at salaries ranging from $1440 to $1800 per annum, for investigating grain-dust explosions and fires in grain mills and elevators throughout the various parts of the United States. Traveling expenses and sustenance will be provided. 2428.

CIVILIAN POSITIONS

SEVERAL INSTRUCTORS in mechanical engineering are needed by one of the large state universities in Middle West; men having specialized training and experience in machine design, gas-power engineering and general laboratory work. Give complete statement of training, experience, minimum salary expected, and recent photograph. 1045.

DRAFTSMAN with at least five years' experience in the detail of machine parts. Permanent position. State age, experience, salary expected, and references. Location near New York City. 2012.

YOUNG MAN not over 35 and not subject to military draft. Must possess some technical training or experience in mechanical lines including drafting. Energetic man with executive ability required. Salary to start, $1300 to $1500. Location New York. 2166.

PHYSICISTS, ENGINEERS, DESIGNERS AND DRAFTSMEN for work of research development and design related to problems of telephonic, telegraphic and radio communication, which are matters of public importance. Opportunities for such men in both temporary and permanent positions. Apply by letter. Location: New York. 2178.

DESIGNERS, DETAILERS and TRACERS for chemical plant. Location Philadelphia. 2370.

MEN with mechanical engineering training, in connection with the various operating and test problems in operation of a large power plant. (*a*) Two junior engineers who have had experience in test work on various types of power apparatus to start at $100 per month. (*b*) For the shift-operating jobs three vacancies, starting with salary of $150 per month. Numerous opportunities for promotion; men who make good always considered for transfers to various other plants. Location Virginia. 2371.

ENGINEERS to train and develop in the fundamentals of a New York firm primarily engaged in the distillation of coal tar with the resultant principal production of bituminous road and roofing materials, with the ultimate object of filling operating positions in various plants as foreman, head chemist, assistant superintendents, or superintendents. Preferably, but not essentially, men of chemical-engineering training. As contemplated work will eventually be of an executive nature; ability to handle men is a desirable asset. 2374.

DESIGN DRAFTSMEN on plant layout. Not necessarily technical graduate. Salary $30 to $35. Location New York. 2383.

THREE TECHNICAL GRADUATES for steam engineering and general testing. Work covers steel mills in Pennsylvania, Ohio, West Virginia and Indiana. 2384.

YOUNG MAN with experience as engineer or draftsman to assist in sales department. Apply, stating salary expected. Location Pennsylvania. 2386.

HIGH-GRADE DESIGNING DRAFTSMEN on jigs, fixtures and gages, preferably men experienced in this line. Apply by letter stating experience and salary expected. Location New York. 2388.

PRACTICAL STEAM AND FUEL ENGINEER who also has a technical education. 2389.

ASSISTANT ENGINEER to take general charge of engineering work, including bearing application and shop engineering. Send full particulars in reference to past experience, age, and salary expected. Location Ohio. 2390.

PRODUCTION MANAGER, experienced in factory management, to take charge of factory. Prefer graduate mechanical engineer, and if possible a designer of automatic machinery. Man with executive ability and organizing ability, training in modern efficiency methods and factory management who is systematic, thorough and able to plan methods for getting work through the factory and has demonstrated ability to increase production. Factory makes small articles requiring precision machinery and employs 500 to 600 people. Location New York State. 2391.

MAN capable of taking charge of department employing about 100 men. Must thoroughly understand the bleaching, dyeing, sizing and calendering of cotton goods, a good handler of men; should command respect and obedience. Position would pay about $35 per week to start and more after the man was able to demonstrate his ability. Location Staten Island. 2394.

EXPERIENCED MAN capable of aiding in organizing and following up the introduction of a production department along modern lines, at a large factory located in the East. Must possess initiative and originality and be able to handle successfully shop problems. Man who has had experience in hardware or small tool lines preferred. State experience, age, reference and approximate salary required. 2395.

PLANNING DEPARTMENT AND TIME-STUDY MEN. A well-established firm can offer exceptional opportunities for effective and interesting work to engineering graduates who have had substantial experience with modern industrial methods, with special reference to time study, the determination of standard tasks, and planning and scheduling production. In reply state age, education, experience, present and expected salary. Location Massachusetts. 2396.

MACHINE-DESIGNING DRAFTSMAN. Technical graduate with some years' practical experience in a shop and at least 4 or 5 years in drawing room designing as well as making drawings. Desire man who can follow up work in shop and inspect machinery, a special line of stapling machinery for use in box making being manufactured to contract. Salary about $150 to $200 per month, according to qualifications. Location Illinois. 2399.

FACTORY MANAGER to assume complete charge of large firebrick plant. Must be between 28 and 36 years of age, forceful, possessed of technical as well as practical knowledge and able to prove former success in large undertakings. Location Missouri. 2402.

DRAFTSMAN acquainted with smelting work for position in El Paso, Tex. 2404.

VALUATION ENGINEER for important eastern railroad, to take charge of rolling-equipment valuation work. Should have special experience in valuation, cost and depreciation of car and locomotive equipment. Salary $3600 or more, dependent upon qualifications. 2406.

DRAFTSMEN of general mechanical experience. Men of integrity, reliability and industry wanted, with experience in general drafting, design and layout work. State age, details of experience, salary expected and references. Location Delaware. 2407.

DRAFTSMAN with sufficient experience to enable him to lay out machinery in new plants, including the making of drawings covering electric-light and power systems. Permanent position in engineering department. Prefer man with chemical-plant experience, or who has done drafting for consulting engineer. State fully qualifications and past experience. Applicant must be in possession of technical training. Salary $1300 to start. Location southern Ohio. 2409.

PRESS-ROOM FOREMEN. A Connecticut firm over a century old needs young blood in positions of responsibility. Must have knowledge of and be in sympathy with scientific-management methods. Fair salary and a bonus to start. State age, experience in detail, salary expected and present position, also when you could report for duty. 2410.

ASSISTANT SUPERINTENDENT to become superintending mechanical engineer for electric and finishing plant; should have shop experience and be accustomed to handling men. Some knowledge of chemistry and heat processes preferred. Salary to start $200 a month. Location Niagara Falls. 2412.

BOILER MAN fully conversant with every detail of design and construction of steam boilers, particularly water-tube boilers. Must be willing to make an investment in a progressive boiler shop. Location New Jersey. 2413.

NEW YORK CONCERN desiring to extend sales force for tool steels, want men of good address and shop training to educate for the work of salesmen and steel experts. Men between the ages of 25 and 35. Salary depends upon man. 2414.

MECHANICAL DRAFTSMAN for position in Omaha. Car and locomotive work. Application can be made through New York office. 2415.

POWER-PLANT MEN experienced in industrial lines, design and construction of steel and power plants. Location New York City. 2418.

POWER SUPERINTENDENT to take charge of a power plant near New York City, consisting of 2600 b.hp. of stoker-fired B. & W. boilers burning anthracite, 2500 b.hp. of B. & W. wasteheat boilers, and 15 prime movers—steam turbines and Corliss engines—up to 1500 I.hp. driving d.c. generators and air compressors. 2420.

SALESMAN familiar with time- and cost-keeping methods. Salary and commission basis. Headquarters New York. 2421.

DRAFTSMEN AND FIELD MAN. Young man with knowledge of anthracite-colliery practice. Location Pennsylvania. 2422.

YOUNG MEN with technical training in M. E. course to enter employ of company manufacturing flow meters. Rapid advancement to engineering work in power plants or sales. Location Massachusetts. 2423.

SAFETY INSPECTOR. Man with mechanical training, capable of making intelligent suggestions to engineering department for the provision of all necessary safeguards to comply with the requirements of the law and to make a plant as nearly mechanically safe as possible. Should be well qualified with educational methods to be employed in accident-reduction work. Position will pay $2000 a year. Location New England. 2424.

SALESMAN wanted for an old established firm. Must be cleancut, energetic salesman, not an order taker. Must have thorough knowledge and acquaintance with the automobile trade. While a certain amount of mechanical knowledge is not absolutely essential, such will

[illegible] attention of [illegible] conducting a branch office [illegible] expected and state when [illegible] Middle West. 2428.

[illegible] DRAFTSMEN, preferably with [illegible] Location New York. 24[illegible]9.

MECHANICAL ENGINEER with wide experience in all kinds of [illegible] equipment and solution of labor saving problems [illegible] work for a company having a number of large [illegible] in different parts of the country. Good opportunity for the right man. State age, education, experience and salary desired. Location Middle West. 2430-A.

MECHANICAL ENGINEER having practical experience, particularly in handling and conveying equipment, to study labor-saving problems in a large industrial plant and make recommendations. Good opportunity for the right man. State age, qualifications and salary desired. Location Middle West. 2430-B.

SALES ENGINEERS for hand stoker. Will pay liberal commission on the gross sales price, advance a drawing account of $150 per month. Man should have a technical foundation and be familiar with combustion problems. Would expect a man to spend two weeks with organization to gather selling data, facts and operation of the stoker, thoroughly equipping him for work. Location New England. 2431.

TOOL DESIGNERS AND DRAFTSMAN, particularly those who have had experience on small interchangeable parts. Paying the highest wages obtainable in return for first-class men of engineering ability, also paying a 12½ per cent bonus quarterly, or at the end of full bonus periods, to all employees based on wages earned and for faithful and continuous service. Location New England. 2432.

METALLURGIST, RESEARCH AND EXPERIMENTAL ENGINEER in a New England factory machining and grinding small parts from alloy steel. Man with technical training preferred. 2436.

MAN TO TAKE CHARGE OF SPECIAL CLASS in steam engine practice. The course will consist of one hour a week in the class room and one night of two hours in the engine laboratory. Class will not deal with the students of the regular engineering course, but with the men who are connected in some way with steam engine work, and who wish to obtain a knowledge of the practical and scientific principles underlying the operation of different types of steam engines. Location: New York. [illegible]

YOUNG ENGINEER to take up safety work in connection with plant and to take general charge of the building inspection. Location: New England. 2438-A.

CHIEF CHEMIST in connection with investigation work involved in the manufacture of product. 2438-B.

ASSISTANT MECHANICAL ENGINEER in large manufacturing plant. Young man with experience on pumping machinery preferred. Location New Jersey. 2439.

MEN AVAILABLE

MECHANICAL ENGINEER, EXECUTIVE. Technical education. Two years' commercial experience. Six years as designer on steam turbines and power plants. Five years as works manager of metal-working plant. Desires position as works engineer or assistant to executive in manufacturing or engineering firm. Excellent health and habits. Thirty-one years old, with family. L-392.

FACTORY EXECUTIVE, MASTER MECHANIC OR PLANT SUPERINTENDENT. Age 39. 18 years' experience as production superintendent in the manufacture of engines, condensers, high-vacuum air pumps, centrifugal pumps, etc. General engineering work, both medium and heavy. Has traveled extensively in connection with field work. Good executive, of pleasing personality, alert and resourceful, exercising well-balanced judgment in all dealings and retaining confidence of organization. L-393.

BUILDING EQUIPMENT ENGINEER seeks connection with a manufacturing or construction concern requiring the services of an [illegible] with [illegible] experience in the design, purchase, construction [illegible] plants, heating, ventilating, lighting, refrig[illegible] [illegible] and [illegible] systems. Has also been very successful in [illegible] offices, departments, etc. Services available [illegible] L-3[illegible]4.

[illegible] ENGINEER. Technical graduate, age 25, with [illegible] anti-friction bearing experience, desires position in engineering or engineering sales. Salary $1500 per annum. L-395.

MECHANICAL ENGINEER. Technical graduate, age 38, with 14 years' experience in industrial work as draftsman and engineer, in the manufacture of soap and illuminating gas, and in coal mining and plant construction. At present chief draftsman for a chemical plant. Desires position as chief draftsman or mechanical engineer. Salary $2500 to $3000. Location preferred, East. L-396.

MECHANICAL SUPERINTENDENT. Age 40, broad experience in design, construction, maintenance and operation of machinery, power and industrial plants. Salary $4800. L-397.

EXECUTIVE. M. E. education, age 39, married. Several years' experience in handling men in field, shop and office. Experienced in construction and operation of large lumber-manufacturing plants. Department and territorial manager for large corporation manufacturing and selling mechanical lines. Executive with company contracting for, designing and installing coal-preparation plants. Will consider opportunity in foreign or domestic field. L-398.

CHIEF DRAFTSMAN OR ASSISTANT CHIEF ENGINEER. Mechanically trained, age 29, married. Over four years' practical experience in design and manufacture of jigs, fixtures, gages and tools. Capable of handling men. At present in charge of a vital department of large munition manufacturing concern. Foreign positions considered. L-399.

GRADUATE MECHANICAL ENGINEER of leading technical school desires position of executive nature in connection with building heavy machinery or plant-construction work. Six years' practical experience covering shop work, designing and business. At present engaged in specialty of engine design. L-400.

COMBUSTION AND STEAM ENGINEER. Associate-member, age 29, married. Technical graduate, over six years' experience along lines of power-plant tests and efficiency work. Extended experience with competitive, acceptance and efficiency tests of power-plant equipment, turbines, engines, condensers and auxiliaries, stokers, soot blowers, brick, feedwater regulators, gages, meters, etc. At present employed. Location New York City or vicinity preferred. Salary $2250. L-401.

PLANT ENGINEER. Graduate mechanical engineer with 13 years' experience in the design, erection and operation of power plants and manufacturing machinery. Specialist in the operation of power plants and the repairs and maintenance of machinery. Well trained in the use of electricity as applied to machinery. Most familiar with the equipment found at coal-mining properties. L-402.

MECHANICAL AND ELECTRICAL ENGINEER. Technical graduate, age 35, married. Good executive, with 11 years' experience. Engaged in public-utility work embracing construction, operation and maintenance. Specialist in power generation and distribution. Salary $3600. L-403.

MECHANICAL AND ELECTRICAL ENGINEER. Technical graduate, age 28, with manufacturing experience on gas producers, internal-combustion engines, pumps, compressors, electrical motors, generators, and measuring instruments. General knowledge of power plants, storage batteries, and electrical distribution. At present chief of bureau of gas and electricity in large city. L-404.

PURCHASING ENGINEER of greatest varied experience will change for responsible connection, in charge of active and large organization paying commensurate salary. L-405.

EXECUTIVE MANAGER. An executive of ability and aggressiveness, a mechanical, technical graduate, at present employed, desires to connect with a manufacturer whose business may need systematizing and building up as to organization and production. Has had a varied experience in different branches of manufacturing, operating industrial plants along lines of scientific management, and is fully conversant with modern methods of manufacturing and marketing product. Only interested in a permanent position offering good possibilities for improvement. L-406.

At the Massachusetts Institute of Technology the faculty changes have introduced some new problems since there has been so much demand by the U. S. Government and by industrial corporations related to the war for men of technical skill. So great has been this draft that in the department of electrical engineering one-third of the staff has been called away, in mechanical engineering a dozen men have gone into war work while civil engineering, chemistry, naval architecture and the other departments have sustained serious losses.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and a Selected List of Engineering Articles

British Railways and the War

A PAMPHLET published in London by F. A. McKenzie tells of the part played by British railways in the war.

Before the war the British and German railway organizations presented a striking contrast. The German railways were almost wholly state-owned, and many of them built primarily for purposes not of commerce but of strategy. Railway administration was most closely allied to that of the German Great General Staff. Even the cars were built to a size that could be employed for transporting the maximum number of men, or, in the case of freight cars, gun carriages and war materials.

The British railways, on the other hand, were privately owned and built solely for commercial purposes. It was the business of the railways to provide for the needs of the communities they served and obtain a fair return for their shareholders and nothing else.

There was only one thing done in the way of militarization of transports. In 1871, after the Franco-Prussian war, the British government was empowered by act of Parliament to acquire by royal proclamation any or all of the railways of the United Kingdom in time of war. There were in existence two organizations to deal with this situation. One, a committee of railway managers, first known as the War Railway Council and afterward as the Railway Executive Committee, was to act as a central organization and to coördinate the activities of the different railways in war time. Working in coöperation with it was the Engineer and Railway Staff Corps, a volunteer organization of railway workers, whose purpose was to develop schemes, methods, and personnel for the war railway service. It was composed of general managers of leading railways, prominent contractors, engineers and other railroad men.

Both of these organizations worked in conjunction with the Director-General of Military Transports, and by 1912 complete plans of operation were worked out. In fact, every railroad manager had in his safe a confidential, sealed, unopened document detailing a scheme of mobilization. In it he was told exactly what to do; the trains to be moved; their starting points and destinations, and the entire schedule of running if war came.

On August 4, 1914, the day that war was declared, the railways of England, Wales and Scotland, but not Ireland, were taken over by the government. The terms of compensation to the railroads were not announced at that time, and the lines remained the property of the companies.

At first the sole purpose was to facilitate the movements of troops as the war developed, but as economy became more and more essential the scope of the Railway Executive Committee became extended until now it is in supreme command.

A feat of which British railroad men are quite proud was the transportation of the expeditionary force, numbering 120,000 men, with a vast amount of material of war to Southampton for embarkation for France, simultaneously with the mobilization of the territorials and without essentially disturbing the usual traffic.

Altogether, at Southampton, for example, for practically every day of the first three weeks of war the London and Southwestern Railway handled during a period of 14 hours no fewer than 73 military trains, including the running of them to the boat side and the unloading of the full equipment and ammunition and horses. The trains arrived at intervals, averaging 12 minutes, and practically every train, without exception, came in on schedule time.

To American railroad men it will be of interest to hear that this rapid transportation of the troops to Southampton is recognized by the British railroad men themselves as having been possible only because the docks there had been carefully planned by the railway company for the handling of large masses of men and quantities of material. The trains conveying the troops and freight were run right down to one of the berthing stations; they were emptied there with the greatest expedition and were then sent back. Each train had a prominently placed index number on it by which it was known throughout its trip; its exact time and departure at each place was scheduled and the schedule had to be kept.

One of the noteworthy features of this rapid concentration of troops was that the ordinary traffic of the railways was maintained with comparatively little alteration. Here and there a section of the line was closed for a few hours, particularly sections of some of the junction lines across London, but the general public scarcely realized what was happening.

The conclusion of the final agreement between the government and the companies automatically brought about a great economy in some departments, especially the accounting department and the departments dealing with solicitation of business.

One of the problems which confronted the railroads at the beginning of the war was the demand for higher wages by the men. After the government took over the railroads several agreements were made, culminating in the terms of settlement of November 13, 1915, by which the National Union of Railway Men and the Associated Society of Locomotive Engineers and Firemen undertook not to present to the railway companies any fresh demands for increased bonuses or wages.

The rise of the cost of living proved, however, a stronger factor than formal agreements and several additional war bonuses have since been granted to the men. In justification of these increases in wages it was pointed out that the wages in other industries increased in the meantime. The railway men under the war labor regulations could not leave their employment for other work and it was felt that they could not reasonably be expected to continue work under far lower wages than other men in allied industries in the same districts.

One of the outstanding features of war operation of British railroads is the extensive employment of female labor. Up to the beginning of the war British railways had been very reluctant to employ women even for office positions, but the shortage of men and the desire to release as many as possible for service with the colors caused the introduction of women workers early in 1915.

The pooling system introduced by the government led to

[illegible] extensive economies, such as, for example, the [illegible]ment of the common use of open freight cars, called [illegible]user arrangement. A minor economy was an agreement by the railways to accept each other's "paid" and "to pay" stamps and labels on parcel traffic. This saved much labor and led to a further development in January 1917, when the Railway Executive Committee announced that from a given date the cartage charges for all descriptions of traffic must be paid by the sender at the forwarding station. The whole system of bills and accounts for passenger-goods traffic was thus swept away.

The saving in printing was so extensive that at least one large company was able to sell many tons of paper which had been stored for office use and put this on the market at a time when paper was scarcest.

On July 4, 1917, the Controller of Coal Mines published a system for the purpose of reorganizing the transporting of coal by railways for inland consumption. Under this system England, Wales and Scotland were divided into twenty areas and each area had to take its supplies from certain fixed districts of production. It was estimated that the plan would effect a saving in railway transport of not less than 700 million ton-miles annually. The scheme was based on four main issues:

1 That consumption of coal should take place as near the producing point as possible
2 That in view of the superior facilities offered by the main traffic lines the movement of traffic should follow these routes wherever possible
3 That the movement of coal should, as far as possible, be in well-defined directions—north to south, north to southeast, north to southwest, and east to west
4 That an area producing less coal than sufficed for its own need should not send any portion of its output to other areas. That an area producing more coal than it required for consumption within the area itself should only distribute to adjacent or convenient areas

This scheme did not affect water-borne coal, anthracite, or coke of any description, but was the precursor of other schemes which were to reduce unnecessary traffic in goods to the minimum.

No description of the work of the British railways in the war would be complete without some reference to the service in handling the wounded to which exceptional attention has been paid and for which special trains have been built. In fact, all the great English railway works devoted their utmost skill and care to the ambulance trains, endeavoring to provide the best accommodations for the transportation of the wounded.

The change in the system of management of the British railways, while effected primarily to meet the extraordinary war conditions, was so far-reaching and profound that responsible British railroad men recognize already that the problems in railway management and control raised by the war will not entirely come to an end with the conclusion of peace. A new era has begun in railway management and it will be impossible to go back completely to pre-war conditions. But even if it were possible, it would be undesirable. The British railroad operators have learned a good deal. Coöperation has proved to be better than cut-throat competition.

There are other problems such as the wages of the men after the war and the future of women's labor on the railways, but it is expected that changed conditions after the war may provide in themselves a solution for all these possible problems. British railroads hope that having solved the problems of war traffic and employment in unequal fashion they will master the lesser problems of the coming peace.

Notes from the Engineering Colleges

Throop College of Technology

According to information received from Walter H. Adams of the Department of Mechanical Engineering, comparatively little research work is carried on in mechanical engineering due to lack of time on the part of the instructors. There is being carried out, however, the installation of a wind tunnel housed in a new building to carry on aeronautical research work. This research work will be in charge of Dr. Harry Bateman, who will devote his time mainly to research and will do very little teaching.

With regard to the general laboratory equipment a new building was added last summer, which has doubled the laboratory space available for mechanical-engineering laboratory purposes. A motor-car engine, a 25-hp. air compressor and a 25-hp. heavy-oil engine are in this laboratory, and, in addition to other minor equipment, go to make a very well-equipped laboratory for mechanical-engineering work. Further, the equipment available includes a small engine and a small turbine direct-connected to an electrical generator, with the necessary boiler equipment, condensers, etc.

In the testing laboratory there is a 150,000-lb. Olsen testing machine which was on exhibition at the Panama-Pacific International Exposition. In addition, there is a 30,000-lb. Riehlé tension and compression machine, cement-testing and briquetting equipment, torsion machines, etc.

In the hydraulic laboratory they have a Pelton water wheel, water turbine, single- and multi-stage centrifugal pumps, piston pumps and minor equipment.

The following statement is quoted from Mr. Adams's letter:

"Our laboratory is willing to undertake any preparedness work which it is possible to do with the staff and apparatus available. Over one-third of the students who have entered the Army and Navy have come from the mechanical-engineering course in spite of the fact that we are offering six courses at the College. Last year Throop College was designated as one of the branches of the Reserve Officers' Training Corps, thus initiating work in military training at the College. So far, Throop College of Technology is the only Engineer Unit of the Reserve Officers' Training Corps in the country. This year our professor of military science and tactics will be Captain Charles T. Leeds, Corps of Engineers, U. S. Army, Retired. Captain Leeds is a graduate of West Point and the Massachusetts Institute of Technology, so that it is expected to develop a strong course in military engineering here at the College. We have formed no special units such as ambulance or aviation corps, as our men have gone into all branches of the service."

The first locomotive for American war-service railroads in France was completed in 20 working days, and engines of this type are now being turned out at the rate of about 30 per day. About 680 of these locomotives and over 9000 standard-gage freight cars are on order. The locomotive weighs about 166,400 lb., with the tender about 275,000 lb.—*Official Bulletin.*

U. S. BUREAU OF STANDARDS

The Bureau of Standards, as shown by the following report of its activities, is continuing its active work both on war problems and problems of what may be called peace activities. A significant feature of these activities is the close and growing collaboration between the Bureau and the industries. Thus, as seen from the present report, the Bureau is preparing material for the use of manufacturers of glass pots, and even making pots in its own plant which will enable American manufacturers to produce the more difficult types of glass.

Graphite crucibles experimentally made by the Bureau have been shipped to various foundries for purposes of tests under actual shop conditions.

At the same time work of great practical interest is being carried on in lines requiring a high degree of preliminary scientific training for its prosecution. Thus, the Bureau's study of dicyanin stained glass has yielded unexpectedly satisfactory results, and long infra-red radiations have been successfully photographed. In fact, an invisible spectral region as large as the entire visible spectrum has been thus made accessible to photographic methods in ultra-red. Ten or twenty years ago this would have been justly spoken of as an epoch-making achievement in experimental research, but in the last decade the world has grown so accustomed to great achievement that it is difficult to attract more than its passing attention. This does not, however, detract from the value of work done.

Safety Belts for Aviators

The Bureau of Standards has prepared specifications for leather to be used in the construction of safety belts for aviators.

Lubricants

The Bureau has been engaged on the development of specifications for airplane-motor oil in coöperation with those interested in this problem, including representatives of refining companies. The Bureau has an aero-mechanical engineer engaged in developing and describing an oil suitable for airplane motors. This expert is also working with the sub-committee on lubricants of the International Aircraft Standardization Board.

Optical Glass

The work on special clay pots for making optical glass is progressing rapidly. Pots as large as 28 in. in diameter have been made from porcelain mixtures. Lining of very good mixtures have also been applied to clay pots. In this connection the Bureau is preparing material for the use of manufacturers, as porcelain lining for the glass pots now being made commercially. A large plaster mold has been completed at the Bureau to be used in "casting" pots, and sufficient material has been prepared for "casting" a 28-in. pot in the near future. The use of pots purchased in the open market seems to preclude the possibility of making the more difficult glasses. The Bureau, therefore, is making pots in its own plant, and the work is progressing very rapidly. It is believed that when these are ready, satisfactory glass of all kinds can be made. During the past month two melts of light flint glass, one of a dense flint glass, three of a light crown glass, and three of boro-silicate glass have been successfully completed by members of the staff of the Bureau.

Graphite-Crucible Development

Twenty-six finished experimental crucibles have been completed for service testing in actual practice. These have been shipped to various foundries for this purpose. They are made in sizes used in industrial practice.

Stucco and Plaster

In the investigation of the durability of stucco and plasters, two small test buildings just erected on the Bureau of Standards' grounds have been coated with special stucco in order to study the weathering effects on this type of stucco, and with the special type of construction used. These form a valuable addition to the test structures already erected for this purpose.

Building Stones of the United States

In the investigation of building stones available in this country for structural purposes, 30 different specimens were submitted to laboratory test and examination. These included the determination of specific gravity, or absorption, and of the compression and transverse strength. A freezing and thawing machine is being erected for this work. This will simulate actual weathering conditions, and will be used to determine the life of various types of stones under various weather conditions.

Ultra-Violet Radiation from Quartz Mercury-Vapor Lamps

The increasing importance of quartz mercury-vapor lamps makes it very important that the methods for measuring total radiation and ultra-violet radiation be carefully studied. The Bureau is reducing these measurements of routine operations. Iu the final standardization of such lamps, the Bureau will be in a position to specify the intensity of the invisible ultra-violet radiation in absolute units. Such certification will be analogous to the rating of ordinary electric lamps in terms of candlepower.

Infra-Red Photography

The Bureau's study of dicyanin stained plates has yielded unexpectedly satisfactory results. Infra-red radiation of waves longer than 11,000 Angstron units (1.1 microns) have been successfully photographed, using the iron arc and cobalt as light sources for this purpose. An invisible spectral region as large as the entire visible spectrum is thus made accessible to photographic methods in infra-red. The work was deemed of such importance that maps of the solar spectrum were prepared, covering the region from 6800 Angstron to 9600 Angstron units. The work has been in active operation during the past month.

Exposure Tests of Steel Sheets

A visit was made to Pittsburgh and Annapolis to inspect the steel sheets exposed by the American Society for Testing

[illegible] undoubted evidence that the [illegible] better than the uncop- [illegible] conditions at Annapolis have [illegible] point. It is learned that at Ft. Sheridan [illegible] advanced far enough to justify drawing any conclusion.

News of Other Societies

Southwestern Society of Engineers

The annual convention of the Southwestern Society of Engineers was held at El Paso, Texas, October 18 to 20 inclusive.

The guest and speaker of the Convention was Dr. Ira N. Hollis, President of The American Society of Mechanical Engineers and of the Worcester Polytechnic Institute. His principal address, The Engineer in the Present War, emphasized that men, not inventions, will win the war, the keynote being struck in his words: "The blood of our children, the youth of America, only will solve this war. After all, it is not an engineer's war—it's a war of industrial organization."

Dr. Hollis again addressed the convention at the luncheon at the Ninth Engineers' Camp, Major O'Connor commanding. At this time he lauded the work of the United States destroyers in the war zone, stating they were far superior to anything in the British or German Navies. He again spoke to the society at the annual dinner that closed the formal session, the keynote of this address being that "America is a country of united people," quoting, "We have something now in the country the world has never seen before—three thousand miles of people with the same thoughts and the same ideals."

The opening address, "The Engineering School and the War," by President Barnes, emphasized the lack of research and executive type of engineers, and the belief that the war will teach the schools the need of developing their courses to train men along these lines.

The most enjoyable morning was spent with the Ninth Engineers' Camp, Major O'Connor commanding, and the Eighth Engineers' Camp, Major Peterson commanding, at which sessions Pontoon Bridge Building, Field Surveying, Fortification Work, and Trench Building were thoroughly demonstrated. These sessions, bringing the membership in close touch with Army Engineering, were especially enjoyable and beneficial. The stories of the troubles of cantonment construction as were found at Camp Codie, Deming, N. M., was carefully explained by C. A. Tilton, an auditor of contractor, and Major C. H. Miller, Engineer-in-Charge. The success of the construction of this cantonment against possibly the greatest odds at any of the camps speaks well for American engineering ability, and proves that the American engineer can construct successfully even if the resources at hand are meager.

The address of Dean G. M. Butler, of the University of Arizona, upon Some Effects of the Draft Law on the Arizona Mining Industry, very clearly brought out the problems that the Arizona mining companies have been facing during this great period of stress.

Nominations of officers for the coming year were made as follows: President, Dean G. M. Butler, University of Arizona; First Vice-President, Dean S. H. Worrell, Texas State School of Mines; Secretary, C. E. Barglebaugh; Treasurer, R. W. Goddard. For Directors to serve three years, Messrs. W. E. Robertson and Gerald Sherman, the following officers holding over as Directors: Messrs. Barnes, Gillis, Gladding and Andros.

At the present time the membership of the Society is 119, and it is interesting to know that practically 20 per cent of the membership is now in war service. This, and industrial conditions in Arizona, brought about a smaller attendance than usual, but the enthusiasm and interest in the meetings made up in a large measure for the shortage.

Gas as Gasoline Substitute

The advantages and disadvantages of gas as a substitute for gasoline in motor traction are discussed in a report just issued in England by the executive committee of the British Commercial Gas Association, which says, in part:

"When gas is used on a mobile vehicle several limiting conditions present themselves, inasmuch as the gas for driving the engine must be carried by the vehicle itself. The question of storage, therefore, arises first.

"From information that has appeared in the technical press, the use of gas for motor traction has been successfully worked out by Messrs. Barton Bros., of Beeston. Their arrangement consists of a flexible balloon-like holder carried on the roof of the vehicle. The holders are made of woven fabric treated so as to be impervious to gas and to withstand the effects of weather. They are made in various sizes from 150 to 500 cu. ft. capacity. The gas is therefore stored under a very slight pressure, probably only a few tenths of an inch head (water gage) above atmosphere, and this pressure is steadily maintained as the holder exhausts itself in feeding the engine. So far as the engine is concerned the low pressure of the gas in the flexible holder is of no consequence. The gas flows into the engine just as the air does; that is by the inductive power due to the operation of the engine itself."

The results of an experimental test made by the committee are thus described:

"A car having been equipped with gas reservoirs, it was driven round a district with about the average kind of road and variations of level, and the observations made indicate a radius of action 25 miles per 1000 cu. ft. The average speed was nine miles per hour, including the stopping and slowing down which was several times necessary at crossings, etc., but which is, of course, consistent with everyday conditions.

"Results obtained at Coventry show that the brake power developed by a petrol motor when driven by gas is about 85 per cent of the power developed by petrol, and that this proportion is fairly constant over a wide range of speeds; also for equal brake power on test bench one gallon of petrol appears to be equivalent to 250 cu. ft. of gas.

"Our own observations derived from general running of a vehicle on petrol and gas point to a ratio less favorable to gas, namely, that one gallon of petrol is equivalent to 300 cu. ft. of gas.

"Much, however, of course, depends upon the quality of the gas and the kind of petrol used, there being several qualities of both procurable at the present time.

"Regarding the equivalents of gas and petrol, the gas supplies in different parts of the country are, like electric supplies, not standardized either as to price or quality, and it will be found that the gas obtained at some places will give a better mileage than gas obtained in another place. The gas equivalent is, however, unlikely ever to be higher than 300 cu. ft. per gallon of petrol but may be as low as and even lower than 250 cu. ft. These figures, together with local prices for gas and petrol, will enable those interested to

calculate the relative costs of running." (*Journal of Commerce*, October 16, 1917, p. 9)

Industrial Reconstruction

An important manifesto on industrial reconstruction which has just been issued bears the signatures of more than forty well-known business men and university professors, and of a still larger number of officers of trade associations. The manifesto has also the support of the editors of some seventy trade and technical journals. The scheme outlined in the manifesto is put forward as the practical outcome of all the authoritative suggestions that have been made during the last three years for the organization of British industries and the development of trade and commerce.

Concerning the needs of industrial reconstruction the signatories say that to meet the urgent needs of the times it will be necessary to increase considerably our efforts to develop British industries on the following lines:

1 The mobilization of each industry for common action
2 A greater degree of coöperation between manufacturers
3 Coöperation between labor and capital and the avoidance of industrial strife
4 A more complete association between scientific institutions and traders
5 Education better adapted to our commercial needs
6 Each industry to be studied as a whole, and freed from unnecessary internal competition
7 Every trade to present a united front to foreign competition
8 Output regarded as a duty by both capital and labor
9 Encouragement by the Government of the activities of traders, with a minimum of interference.

It is contended that the matter cannot be left to chance, and that some national scheme is necessary which shall insure the securing of these objects.

Finally the manifesto puts forward under six headings a scheme for industrial reconstruction. It is suggested that the basis of the scheme should be a vocational franchise, which would make possible the organization of each trade separately under a trade council composed of capital and labor, and the decentralization of a large proportion of national work now attempted by Government departments. The Government, it is proposed, should establish a department to promote or encourage trade, and the first function of this department should be to create representative trade councils in every trade. It should be assisted by an advisory council, consisting of the chairman of all the trade councils, and should comprise special departments for export and tariffs, industrial and scientific research, commercial education, statistics and finance, welfare and exhibitions and advertising.

Generally, the scheme involves the establishment of a complete new system of trade government comparable to our existing system of local government, with a ministry at the head with powers similar to those of the local government board, controlling numerous trade councils, with powers comparable to those of existing county councils. It recognizes the essential principle that industrial interests should be grouped by trades and not by localities.

The manifesto, signed as it is largely by manufacturers and officers of employers' associations, is described definitely as an olive branch to labor. It invites the workers cordially to join with the management in the self-government of industry, and offers them an equal status and responsibility on the controlling body. (*Journal of Commerce*, October 27, 1917, p. 2)

International Aircraft Standards

The following list of specifications for aircraft has been adopted to date by the International Aircraft **Standards** Board of the Council of National Defense, F. G. Diffin, Chairman.

1L1. List of specifications
1G1. General specifications for the testing and inspection of metallic materials
1A1. Methods of chemical analysis
2S1. Chemical compositions of steels
2N1. Ingot aluminum
2N2. Ingot copper
2N3. Spelter
3S1. Carbon steel for case-hardening
3S2. Medium-carbon steel bars and billets
3S3. Alloy-steel bars and billets, 100,000 lb. per sq. in. tensile strength
3S4. Alloy-steel bars and billets, 125,000 lb. per sq. in. tensile strength
3S5. Alloy-steel bars and billets, 150,000 lb. per sq. in. tensile strength
3S6. Alloy-steel bars and billets, 175,000 lb. per sq. in. tensile strength
3S7. Alloy-steel bars and billets, 200,000 lb. per sq. in. tensile strength
3S8. Alloy-steel bars and billets, 225,000 lb. per sq. in. tensile strength
3S9. Alloy-steel bars and billets for case-hardening, 170,000 lb. per sq. in. tensile strength
3S10. Alloy-steel bars and billets for case-hardening, 190,000 lb. per sq. in. tensile strength
3S11. Tolerance on steel bars
3S12. High-strength steel wire
3S13. 19 non-flexible steel-wire cable
3S14. 7 by 7 non-flexible steel-wire cable
3S15. 7 by 19 extra-flexible steel-wire cable
3S16. Wire for acetylene welding
3S17. Wire for electric welding
3N1. Gun-metal castings
3N2. Manganese-bronze castings
3N3. Phosphor-bronze castings
3N4. Naval brass or equivalent alloy bars
3N5. Naval brass or equivalent alloy sheet
3N6. Sheet brass
3N7. Brass tubes
3N8. Sheet copper
3N9. Phosphor-bronze strip
3N10. Babbitt metal
3N11. Aluminum-alloy castings
3N12. Sheet aluminum
4P1. Turnbuckles
4P2. Ferrules and thimbles.

Wood for Aeroplanes

The Forest Service, Department of Agriculture, authorizes the following:

When the United States entered the war the need for wood to build airplanes quickly created a difficult problem. Most of the air-seasoned wood available had been bought for air-

[illegible] by the allied nations abroad. Thorough air seasoning of [illegible] requires from one to three years, according to the size and kind of wood. Kiln-dried stock under the [illegible] ordinarily used has frequently proved unsatisfactory and for that reason airplane manufacturers have been reluctant to use it. If the needs of the fighting forces were to be met adequately and without prolonged delay, it was essential that methods of conditioning should be available in which full confidence could be placed.

Long before this situation developed the forest products laboratory of the Forest Service, at Madison, Wis., had been making a scientific study of the drying of wood, and had developed a method of drying which has been very successful with all the woods tried. Several kilns have been built at the laboratory for experimental purposes and a number of demonstrations made in commercial kilns. Ash and spruce are the woods most in demand for airplane construction, and anticipating the present situation the Forest Service secured a shipment of partially air-seasoned ash and spruce plank for preliminary tests.

This material was kiln-dried without injury. Later thoroughly green Sitka spruce, white ash (northern and southern), white oak, Douglas fir, western white pine, and mahogany were secured in the log for testing. The spruce and ash logs were cut up and the green material from each species divided into three matched groups. One group of each species was tested green, another had been set aside to be tested when it has air-dried, and the third group was kiln-dried, trying several methods, and then tested.

Only the results of tests on the spruce have so far been analyzed. Comparison with standard tests which had already been made shows that Sitka spruce can be kiln-dried from the green condition with no more, perhaps less, injury to its mechanical properties than by air seasoning. Definite specifications have been prepared for kiln-drying spruce green from the saw for airplane construction, and if rigidly enforced, they will insure kiln-dried stock of this species equal to air-dried stock.

A preliminary study of propeller construction has shown the need of such information on propeller woods. The testing of the ash and other species now on hand, which include several propeller woods, is being pushed as rapidly as possible, and there seems reason to expect as favorable results as for the spruce. (*Official Bulletin*, October 18, 1917, p. 5)

Smoking Rules for Factories Adopted

Announcement is made by the New York State Industrial Commission that it has adopted the new "smoking rules" as Rule 15 of the Industrial Code, to take effect immediately. This gives the new rules force and effect of law.

According to the rule, smoking may now be permitted in a factory only upon written application by an employer, approved by the State Industrial Commission after inspection by its staff and under certain conditions to be prescribed. The permit shall state the conditions under which each individual permit is issued.

As a general proposition, aside from those conditions hereinbefore specified, smoking may be permitted where conditions are substantially as follows: (1) In buildings where the contents are either non-inflammable or incombustible. (2) In buildings of mill construction where the contents are incombustible. (3) In factory buildings, in separate rooms set apart for the purpose as mentioned before. (4) In foundries and forge shops.

No permit will be issued for smoking in any factory where explosives are manufactured, used or stored. Where smoking is permitted fireproof receptacles must be provided in which to deposit all waste or other inflammable material. Wherever smoking is permitted, the use of celluloid eye-shades, cuff protectors, or other similar devices is prohibited. Portions of any factory where smoking is permitted must be posted. (*Journal of Commerce*, October 29, 1917, p. 17)

Weights of Mercedes Motor Parts

The following interesting table is a recapitulation of the weights of the parts of the Mercedes motor:

Crankshaft complete	34.8 kg.
Lower half of crank case	39.97 kg.
Upper half of crank case	31. kg.
Six cylinders complete	61.24 kg.
Six connecting rods complete	13.86 kg.
Six pistons complete	18.7 kg.
Camshaft complete	21.1 kg.
Carburetor	6.6 kg.
Water pump with shaft and housing	6.6 kg.
Oil pump with shaft	5.85 kg.
Two operating magnetos	13. kg.
One starting magneto	4. kg.
Inlet pipe and ignition wire casing	11. kg.
Miscellaneous parts	5.5 kg.
Total	273.22 kg.
Exhaust pipe complete	7.5 kg.
Radiator empty	26. kg.
Total	306.72 kg.

This Month's Abstracts

New ways to burn crude oil or gas attract an increasing amount of attention in these days of fuel stringency. In the present issue abstracts will be found of descriptions of two such ways; one by W. A. Janssen and the other by A. C. Ionides.

In the section Air Pumps is described the Globe-Johnston rotary vacuum air pump, said to produce a high vacuum.

The section Engineering Materials is particularly rich in good articles this month.

An abstract from a paper before the Ceramic Society of Glasgow presents an explanation why silica brick is so much more resistant in high-temperature firing than ordinary brick.

Guillery gives new data and methods for obtaining more reliable results with the Brinell hardness test.

Prof. W. M. Thornton, by repeating tests formerly carried out at the National Physical Laboratory, determines the factors affecting the heat-insulating value of a roofing material and presents data on the behavior of such materials.

Grain-size inheritance in iron and carbon steel forms the subject of a paper before the American Institute of Mining Engineers, while Herbert J. French gives data obtained in an experimental investigation of the physical-chemical properties of chrome-nickel steels. Finally, several abstracts taken indirectly from German periodicals are reproduced in the same section.

In the section Internal-Combustion Engineering attention is called to an abstract of a French official report on the use of alcohol for fuel purposes in internal-combustion engines and some details of the new Evinrude-Hvid oil engine.

Tables and data are reproduced from a British periodical on the design of coil springs.

In the section Thermodynamics particular attention is called to an abstract of paper by W. C. Stuart, Mem.Am.Soc.M.E., on the performance and design of surface feedwater heaters. Lack of space prevented giving a more detailed abstract of this interesting paper.

REVIEW OF ENGINEERING PERIODICALS

Aeronautics

The Metallurgy of Cast-Iron Aeroplane-Engine Cylinders, F. W. Adams

An article giving data on the mixtures and processes used in the casting of cast-iron aeroplane-engine cylinders.

The tests used are chemical analysis, water-pressure test for porosity, and size-limit test.

The chemical constitution of the iron is specified and usually allows of but little variation, the mixture aimed at being such as will make a cylinder sufficiently hard to insure a reasonable life, but, at the same time, machinable and not porous.

Owing to the thinness of the casting, phosphorus must be relatively high in order to promote fluidity and enable the metal to take the finest parts of the mold. As phosphorus, however, produces brittleness in the iron under shock, its excess must be carefully avoided. Fluidity can also be produced by a high melting temperature, but this has several disadvantages. In the first place more carbon is absorbed by the molten metal, and next, on casting, rapid cooling takes place at critical temperatures, resulting in brittleness and hard patches in the finished casting which cause considerable trouble in machining.

The water test is of great importance. The machined cylinders are tested up to a water pressure of 500 lb. per sq. in. and at this pressure must not show the slightest trace of leakage or even dampness on the outside surface. Failure in this case may be due either to excessive graphitic carbon or blowholes. In the first case a slight leakage usually occurs in the thinner portions of the cylinder and is apparently due to lack of cohesion between the graphite plates and the metal itself.

The original is illustrated by photomicrographs showing the structure of various types of cylinder cast iron. (*Aerial Age Weekly*, vol. 6, no. 7, October 29, 1917, pp. 286-287, 6 figs., *p*)

Air Pumps

Globe-Johnston Rotary Vacuum Air Pump

Description of a rotary valveless air pump designed to produce a high vacuum.

It consists of two main parts, the rotor and the drum, rotating on ball bearings in a specially designed casing. By a small modification the vacuum pump may be converted into an air compressor.

The rotor, Fig. 1, as applied for the vacuum pump, is a hollow member on the outer circumference of which deep double-thread screws are formed. A passage C runs between twin-screw threads A and B into the interior of the rotor. When the machine is producing a vacuum this passage acts as the inlet to the screw threads, but when air is being compressed, it is the outlet. Similarly the pipe F running from the interior of the rotor to the exterior of the machine is the inlet pipe in the vacuum pump and the outlet pipe in the compressor. The screw threads are joined by a large number of narrow partitions or blades D which are equally spaced around

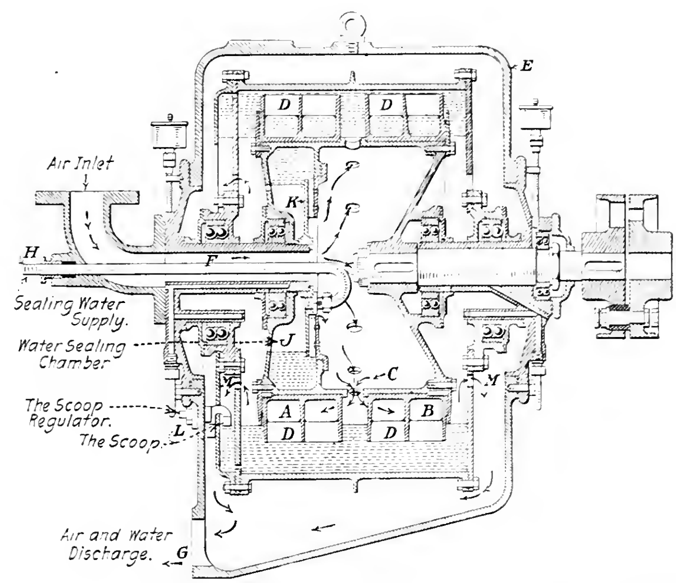

Fig. 1 Globe-Johnston Rotary Vacuum Pump in Section

the periphery of the rotor. The outer and inner edges of these blades are respectively flush with the top of the screw threads and half way down the depth of the threads.

The ring of water is in the first place set up by the action of these blades in conjunction with centrifugal force. Annular rings E, called shrouding blades, fitted to the sides of the rotor and reaching somewhat below the water level on the discharge side, prevent the exhausted or compressed air from returning along the screws when the thread ends leave the water seal.

The rotating drum is a hollow cylinder also running on massive ball bearings. The drum when rotating contains the ring of water and is set eccentrically to the rotor. The relative eccentricity of the rotor and the water ring produces what is called the "working space," Fig. 2. The net circular

[illegible] with the pitch [illegible] rotation is the measure [illegible].

[illegible] pump is a rotating screw [illegible] in conjunction with a ring [illegible] by centrifugal force [illegible]. To put the machine into operation [illegible] through pipe H, Fig. 1, and the pump [illegible]. The water passes through the water sealing [illegible] to the interior of the pump, which it gradually fills until it becomes deep enough to be caught by the partition blades D of the revolving screw rotors A and B. It is thus whirled round the interior of the rotating drum C by these blades.

The friction between the whirling water and the drum causes the latter to revolve also and in a very short time the drum and the rotor are running at practically the same speed. The sealing water continues to flow into the machine until a ring of water is formed within the drum sufficiently deep to submerge the screw threads on the rotor at the point where,

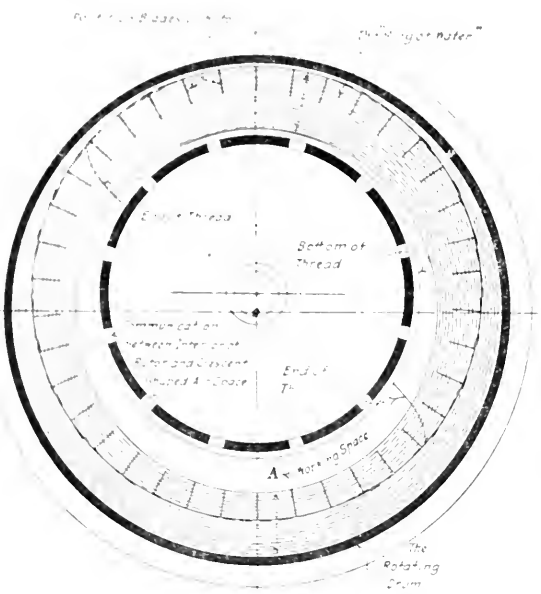

FIG. 2 SECTION SHOWING RING OF WATER IN THE GLOBE-JOHNSTON ROTARY VACUUM PUMP

due to the eccentricity, they approach nearest to the inner periphery of the drum. It is this water maintained in the form of a ring within the drum by centrifugal force operating in connection with the threaded rotor set eccentrically to it, that produces the pump effect.

During the operation of the pump a small stream of water flows continuously into the drum through the pipe H, Fig. 1, and in order to maintain the correct depth in the ring of water a scoop L is provided. The scoop skims half the surplus water and does it continuously while the pump is working. [illegible], vol. 29, no. 340, October 1917, pp. 75-79, 7 figs., [illegible]

Engineering Materials

THE REFRACTORY PROPERTIES OF SILICA. H. LeChatelier and B. Bogitch

It has been found that with clay bricks the arches could not bear the temperature in regenerative firing and would give way in a very short time. On the other hand, silica bricks could stand that temperature. It has not been clear, however, why silica brick is so superior to clay brick. The experiments on the refractory properties of clay carried on by the present investigators give a basis for the explanation of this fact. It appears that clay bricks begin to soften between 1300 and 1400 deg. cent., and, therefore, above that temperature cannot sustain heavy loads without giving way in a continuous and indefinite manner.

They act, therefore, like a vitreous substance, and have no real fusing point, but only an extensive fusibility range.

The difference in the ways in which clay and quartz act is based on the assumption that the latter has a real point of fusion without previous softening, and, consequently, independent of pressure. This has been confirmed experimentally by the writers. When toward 1500 deg. a small cylinder of clay is crushed it can be seen dilating into barrel shape, then completely flattened out into a thin cake, with rounded edges showing, at any moment, properly so-called fracture. When cooled, the crushed mass entirely preserves its former hardness. On the other hand, in the case of a silicon, the first application of the pressure produces no appreciable effect, but on increasing it gradually the test piece breaks abruptly, showing two sliding cones, which are observed in hard materials when working under compression, and the broken fragments do not reunite at all during the cooling. The effort necessary to produce this abrupt breakage decreases gradually with rise of temperature.

The resistance in crushing expressed in kg. per sq. cm. or lb. per sq. in. begins with 170 kg. (2400 lb. per sq. in.) at 15 deg. cent., 120 kg. (1700 lb. per sq. in.) at 1050 deg. cent., and 30 kg. (425 lb. per sq. in.) at 1600 deg cent. These numbers lead by extrapolation to a resistance of 12 kg. (170 lb. per sq. in.) at 1700 deg. cent., the usual temperature of the arches in steel furnaces, a resistance which is about ten times the load sustained by the bricks in the arches. This mechanical resistance, retained up to very high temperatures, is a special peculiarity of silica bricks, and is not found in clay bricks or even in magnesia bricks less fusible than silica.

The reason of the difference is that both clay and magnesia bricks contain basic oxides, such as aluminum, lime, oxides of iron, etc., which all tend to produce a fusible material liquid already toward 1200 deg. Silica, on the contrary, forms a continuous network, in the pores of which the melted mass lodges like water lodges in the pores of pumice stone without diminishing the mechanical resistance. The formation of this network, in consequence of the recrystallization of the silica, is due to the difference of solubility of the different allotropic varieties of silica.

Bricks insufficiently fired whose network is not yet formed are composed of grains of quartz flowing in the metal mass and are plastic like the clay bricks. This explains why insufficiently fired bricks are fusible and useless. When a good silica brick is heated, its strength diminishes with rise of temperature. The reason for this is that the solubility of silica increases with the temperature, and therefore a progressive dissolution of the crystalline network is produced which tends to disintegrate it. This effect is the more delayed the better the network is developed, and it is on this that the quality of silica brick depends before anything else. The problem is, therefore, to study the factors on which the rigidity of the network depends, and these factors appear to be as follows: the proportion of fluxes; the actual temperature of the brick; the good formation of the network; the disintegration of the network through subsequent swelling out.

As regards fluxes, it has been found that the weights of the oxides in the fluxes represent a particularly constant fraction of the weights of the sulphates, on an average 35 per cent.

The temperature which the brick supports depends entirely on the use one wishes to make of it. The highest temperature is in steel furnaces. In ovens for the distillation of coal the temperature is not so high, and, therefore, a double proportion of the basic oxides can be used in the brick which makes its manufacture easier.

The proper constitution of the network is the most delicate part of the manufacture. In order to develop the network, the brick must be kept for a very long time at such a high temperature that the melted magma may be sufficiently fluid. The most favorable conditions appear to be several days firing at a temperature approaching 1450 deg. cent.

The writers state, in conclusion, that all good bricks after heating for an hour at 1600 deg. cent. offer a resistance to crushing at least equal to 10 kg. per sq. cm. The prolongation of heating at this temperature does not materially diminish their strength as compared to what happens with bad bricks. (Abstract of a paper read before the Ceramic Society at Glasgow on October 2, 1917, through *Engineering*, vol. 104, no. 2702, October 12, 1917, pp. 396, e)

BRINELL HARDNESS TESTING OF METALS, M. Guillery

In order to have the results of the Brinell hardness test comparable with each other it is necessary to define the conditions of the test. In the case of steel it is usual to specify them as follows:

Diameter of the ball, 10 mm.
Total pressure, 3000 kg.
Duration of pressure, at least 5 min.

The first two of these conditions are easy to specify, but the third, while theoretically very simple, is in practice impossible to satisfy except in scientific laboratories. In a shop where the number of tests often exceeds 10,000 a day, it is evidently impossible to continue the pressure in each test for 5 min. and it is usual to keep the pressure only for 10 sec. This is liable to cause an error sometimes as high as 8 per cent.

The writer cites the following figures obtained with a constant speed of ball and the pressure being removed as soon as it attained 3000 kg. (Table 1.)

TABLE 1 DATA OF HARDNESS TESTS ON VARIOUS MATERIALS

Impact velocity, kg. per sec.	Dia. mm.	Error	Brinell hardness kg. per sq. mm.	Error	Tensile strength, kg. per sq. mm.	Error	Error per cent
MILD STEEL							
0	4.74	0	159	0	55.6	0	0
12.5.....	4.72	0.02	161	2	56.3	.7	1.2
25	4.70	0.04	163	4	57.0	1.4	2.4
1500	4.60	0.14	171	8	59.8	4.1	7.1
MEDIUM STEEL TEMPERED AND ANNEALED							
0	4.094	0	212.5	0	74.3	0	0
12.5.......	4.074	0.020	217	4.5	76.0	1.7	2.2
25	4.059	0.035	221.5	9	77.6	3.3	4.3
1500	3.975	0.118	227	14.5	79.4	5.4	7

A very simple mechanical arrangement makes it possible to eliminate this source of error. If the pressure is removed as soon as 3000 kg. are attained, the diameter of imprint will be too small by a quantity dD. If, on the other hand, instead of the pressure being stopped at 3000 kg. it is carried to $3000 + dP$, then the diameter of imprint will be increased. Now, if a suitable value of dP is selected, then the error resulting from insufficient duration of action of pressure will be exactly compensated. As a matter of fact, we will have essentially the relation

$$\frac{dP}{3000} = \frac{2\,dD}{D}$$

With an impact of 1500 kg. per sec. we have for the first steel in the above table $dD = 0.14$. Hence,

$$dP = 3000\frac{2 \times 0.14}{4.74} = 177 \text{ kg.}$$

It is quite possible to build an apparatus in which the maximum pressure attained will be regulated by the velocity of impact.

Let us assume that the pressure is transmitted to the ball

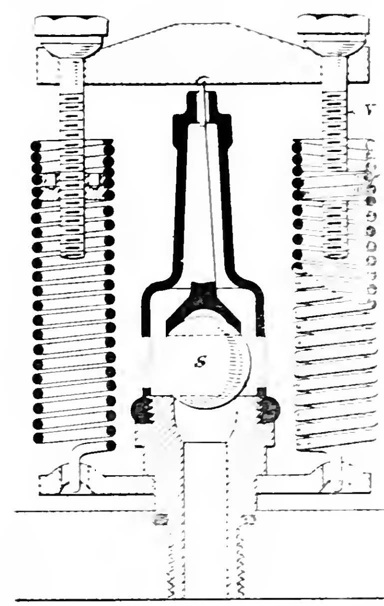

FIG. 3 GUILLERY APPARATUS FOR ADJUSTING THE PRESSURE IN THE BRINELL HARDNESS TEST

by a frictionless hydraulic piston in which the watertightness is insured by a strip of rubber. The pressure exerted on the piston is limited by the lift of the valve formed by the sphere S, Fig. 3, carried on a [illegible] seat. The pressure necessary to lift the valve is then strictly determined by the full section of the seat and the effort applied to the sphere. This effort is produced by the springs, the tension of which may be varied as desired by means of the tightening nuts D, and the useful length, by means of the screws E which act on the spirals themselves of the springs at rest.

For purposes of regulation this arrangement gives two independent variables: length and tension of the spring. The effort opposing the lift of the valve depends on the height of this lift, which increases the elongation, and hence the tension of the spring. The apparatus is regulated by "cut and try," so as to have on a given steel the normal diameters of imprint for two velocities of impact varying

[illegible] 30. The apparatus is at the same time [illegible] the intermediary velocities, as shown by [illegible]

TABLE 2 [illegible] HARDNESS TESTS ON AN IMPROVED BRINELL-GUILLERY APPARATUS

[illegible]	[illegible]	200	[illegible]	600	1000	1,500	3000
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	4.40	4.39	4.39

TABLE 3 FURTHER DATA OF TESTS ON VARIOUS MATERIALS

	Velocity of impact, in kg. per sec.				
	12.5	100	600	3000	
Mild steel	5.67	5.66	5.67	5.68	5.66
Medium steel, tempered and annealed	4.40	4.36	4.36	4.36	4.36
Nickel-chrome, untreated	3.63	3.60	3.59	3.62	3.58
Nickel-chrome, annealed.	2.61	2.62	2.62	2.63	2.60

Theoretically a new regulation should be made for each different metal. However, for ordinary carbon steels and for such special steels as chrome and chrome nickel which have undergone some heat treatment the same regulation holds good, as shown by the following results, Table 3.

This apparatus has been functioning for several months without having ever gotten out of order. On pieces of the same shape and easy to handle the testing is done at the rate of 600 imprints per hour. Of the 10 sec. employed for each operation 8 sec. are for the manipulations and 2 sec. for applying pressure. (*Essai de dureté des métaux à la bille Brinell, Guillery, Comptes rendus de séances de l'Académie des Sciences*, vol. 165, no. 15, October 8, 1917, pp. 468-471, 1 fig., *e*)

The Heat-Insulating Value of Roofing Materials, Prof. W. M. Thornton

In the last-but-one report of the National Physical Laboratory, there is an account of a test of roofing by means of measuring the heat lost from a heated room, which leads to the remarkable conclusion that the rate of emission of heat by the radiation from the covering surface has more effect on the inside temperature than the rate of conduction of heat through the material.

This result is of importance in the roofing of large factories of semi-permanent nature where the temperature depends more upon the covering than in the case of buildings having a closed air space under the roof. In the present case the test of the National Physical Laboratory was repeated by a method the reverse of that used by them; namely, instead of heating a room and measuring the heat lost through the roof, a smaller chamber was made by bolting together slabs of 3-in. thick "nonpareil" cork and exposing its cover to strong radiation. The box was made 18 in. square and 2 ft. deep inside, so that slabs of roofing of convenient size, such as slates, could be placed in position to cover the chamber without requiring special support.

The test consisted in observing the rate of rise of temperature in the chamber from the time the radiation was applied. The method was such as to give good comparative values.

The results obtained confirm the National Physical Laboratory conclusion that the heat-insulating value of a roofing material depends more upon the nature of its surface than upon its thermal conductivity. A sheet of galvanized iron was obtained having a practically mirrorlike surface. Only 111 heat units entered per 1000 sq. ft. per hour, but that the heat transmitted depends largely on surface conditions was seen at once by the increased rate of transmission caused by blackening the surface facing *into* the box, the other surface being unchanged. Reversing the plate so that the outer surface was black and the inner bright more than doubled the lost rate, and when both surfaces were blackened, the large amount of 581 units per hour was transmitted.

A suggestion was made in the National Physical Laboratory report that air spaces in roofing materials might be advantageous. A satisfactory means of doing this is to lay corrugated asbestos cement plates on the thinnest asphalted felt, or any other light sheet material, supported by the roof frames. The effect of this, as seen from the table, is equal to that of an aluminum surface, and where heat insulation and lightness are of the first importance, a strong and efficient roofing can be made in this way at a reasonable cost.

TABLE 4 HEAT TRANSMITTED THROUGH ROOFING MATERIAL EXPOSED TO STRONG RADIATION

	Material	Rise of temperature in testing chamber, deg. cent. per min.	B.t.u. per 100 sq. ft. per hour	Thickness in inches	Weight, lb. per sq. ft.
1	Bright galvanized iron sheet	0.268	111	0.04	1.6
2	Galvanized iron, blackened below	0.40	168	0.04	1.6
3	Galvanized iron, blackened above	0.93	385	0.04	1.6
4	Galvanized iron blackened above and below	1.40	581	0.04	1.6
5	Galvanized corrugated iron after one month's exposure to the weather	0.75	310	0.033	1.28
6	Do., after one year's exposure	1.02	422	0.033	1.28
7	No. 6, painted black above	1.13	472	0.033	1.28
8	Roofing glass, serrated	1.10	453	0.22	2.25
9	Welsh slate	0.81	337	0.17	2.0
10	Westmoreland slate	0.60	248	0.25	4.8
11	7/8-in. T. G. deal covered with asphalted felt	0.30	124	1.0	2.6
12	Corrugated fibrocement after one month in use	0.78	325	0.2	1.8
13	Do., after one year in use	0.80	334	0.2	1.8
14	Do., painted dead black	0.82	341	0.2	1.8
15	Do., "aluminum-finished" outside	0.50	207	0.2	1.8
16	Do., laid on top of thin asphalted felt	0.51	211	0.25	2.0

The main data obtained in the test are presented in Table 4. The "fibrocement" referred to in the table is an artificial roofing material containing asbestos manufactured by a British company. (*Engineering*, vol. 104, no. 2703, October 19, 1917, pp. 405-406, *e*.)

Grain-Size Inheritance in Iron and Carbon Steel, Zay Jeffries

Discussion of the question of inheritance of ferrite grain size from that of austenite, together with the general question of grain refining in steel and iron.

The writer reports on series of tests on grain size in transformation products of iron and steel such as 0.7 per cent carbon steel (in this series of tests, among other things, data were found giving an explanation why cast steel has its grain better refined after two heatings and coolings than after one), 0.2 per cent carbon steel, Armco iron, and finally electrolytic iron.

Because of lack of space only the conclusions reached can be reported here.

1 The ferrite grain size in pure iron, the ferrite and pearlite grain size in hypoeutectoid steel, the pearlite grain size in eutectoid steel and the cementite and pearlite grain size of hypereutectoid steel are not inherited from the grain size of the mother austenite.

2 The only structural feature that is generally inherited from the austenite of hypo- and hypereutectoid steels on cooling through their transformation ranges is the position of the excess ferrite or cementite at the austenite grain boundaries, sometimes causing complete and sometimes incomplete networks which outline the old austenite grain boundaries. Rapid cooling through the transformation range will cause the noninheritance of this structural (network) feature.

3 The austenite grain boundaries themselves are nearly always effaced in all steels, and also in pure iron during the *Ar* transformations.

4 The grain-size refining of steel and iron is brought about by the combined effect of non-inheritance of the transformation products on either heating or cooling, i.e., the austenite transformation products do not inherit their grain size from the austenite on cooling through the transformation range, nor does austenite inherit its grain size from the products which form austenite on heating.

5 In general, in both iron and carbon steel, the larger the austenite grain size, the larger will be the grain size of the transformation products on cooling. This, of course, assumes all other conditions constant except the austenite grain size. An exception is found to this general rule in very pure iron such as electrolytic iron. In this instance small austenite grains may form very large ferrite grains on cooling through Ar_3.

6 In iron and steel, the larger the ferrite, cementite or pearlite grain size, the larger will be the austenite grain size on heating above the *Ac* transformations, or vice versa.

7 The faster the rate of cooling of iron and steel through the *Ar* transformation range, the smaller will be the grain size of the transformation products and vice versa.

8 The faster the rate of heating of iron and steel, other conditions remaining the same, the smaller will be the austenite grain size.

9 The greater the temperature gradient during the transformations in iron and steel on heating or cooling, the larger will be the grain size.

10 If the grain size of a transformation product in iron and steel immediately after the transformation is smaller than the equilibrium grain size of that product under the existing conditions, the equilibrium grain size will be established by the known laws of grain growth.

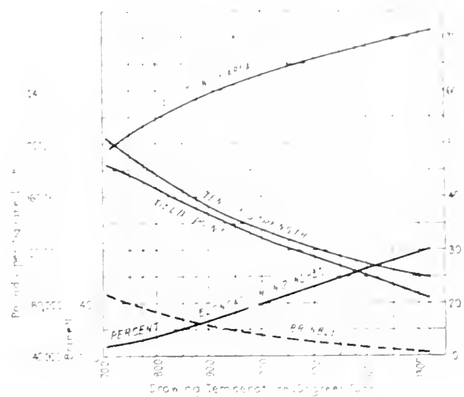
11 A single grain of any constituent in iron or steel (austenite, ferrite, pearlite), when forced by thermal treatment to undergo one of the *A* transformations, must transform from at least one nucleus, but may and nearly always does transform more than one nucleus. (*Bulletin of the American Institute of Mining Engineers*, no. 131, November 1917, pp. 1883-1899, 5 figs., 3 tables, *te*)

Physico-Chemical Properties of Chrome-Nickel Steels, Herbert J. French

Data of tests designed to show the properties which may be developed by heat treatment of certain chrome-nickel steels, especially those lately employed for automobile and aeroplane engine construction.

Standard tensile test specimens (0.505 in. by 2 in.) were heat-treated in a laboratory electric furnace, and the results thus obtained were then checked in actual production by including standard test sections in the ordinary large oil-fired furnaces. All temperatures are given in degrees fahrenheit.

In quenching care was taken to introduce the steel into the oil as quickly as possible after leaving the furnace. It was then kept in motion in the oil for about 1 min.



C	0.35	P	0.014	Cr	0.50

Mn	0.52	Ni	1.16		

Fig. 5 Open-Hearth. Forged to About 1 In. Round and Heat-Treated. Oil-Quenched 1475 Deg. Fahr. Drawn as Given

Tensile test values shown in Figs. 4 and 5 serve to give a good idea of the physical properties which may be developed by heat-treating steel of the following standard specification:

	Per Cent
Carbon	0.35—0.45
Nickel	1.00—1.50
Chromium	0.50—0.75
Manganese	0.50—0.80
Phosphorus, max.	0.04
Sulphur, max.	0.04

The article contains data on two other steels with high nickel and chromium contents. A good representative of such is Fig. 6, where the nickel content rises to 2.56 per cent and the chromium content to 1.01 per cent. In all, five types of steel are discussed.

[illegible] recommended, among other purposes, for the [illegible] aeroplane engine in the United [illegible] they are suited for automobile [illegible]

[illegible] remind, however, that steels of high nickel [illegible] are very susceptible to improper work- [illegible] This refers particularly to heat [illegible] Lower chrome nickel steels will stand more [illegible] manufacturing, and will show the effects of improper working to a less marked degree. What is especially to be avoided is too rapid heating, and particularly heating in an open fire, which leaves the center of the mass of metal cold and the outside "dripping." Quite often the effect of cold working is less serious than when the whole mass of steel uniformly heated is hammered at too low a temperature. This condition of strain can be obliterated if proper heat-treatment methods are employed.

Ordinary annealing may soften the steel so that the hard-

ness test will show nearly normal results, but machining will still be difficult. (*Metallurgical and Chemical Engineering*, vol. 17, no. 8, October 15, 1917, pp. 473-476, 10 figs., *e*)

STRUCTURE OF SCHOOP SPRAYED-METAL COATING, H. Arnold (*Zeits. Anorg. Chem.* 99. 1. pp. 67-72, March 15, 1917. *Engineering* 104, p. 126, August 3, 1917.)

Examining the coatings microscopically (photographs reproduced) the author, of the Metallisator Gesell., finds that the drop of fusing metal is drawn out, by the gas and air currents, into a thread which breaks up into small particles; in the case of aluminum the particles form splashes, from 0.01 to 0.15 mm. in diameter, provided with a short tail and showing a dendritic structure. Polishing and etching of the coatings brings out wavy lines. Zinc, sprayed on glass, partly peels off again and contracts to irregular crescents; tin forms rings frequently double rings. There is no alloying of two sprayed metals, except perhaps with lead and antimony, unless [illegible] heating follows; the union is merely mechanical. [illegible] spray coatings, even of aluminum rolled into [illegible] distinguished from electrolytic and other [illegible] *Abstracts*, Section B. HARDNESS OF COMMERCIAL ALLOYS, P. Ludwik (*Zeits. Vereines Deutsch. Ing.*, 61. pp. 549-554, June 30, 1917.)

Gives the results of measurements of hardness of a large number of the most important technical alloys of Cu, Sn, Pb, Zn, Al, Bi, Mg, Sb, Ag, with the five first-named metals in various proportions and combinations. These alloys include aluminum bronze, german silver, manganin, white metal, magnalium, etc. (*Science Abstracts*, Section B, Electrical Engineering, vol. 20, part 9 [No. 237], September 29, 1917, p. 305)

INFLUENCE OF THE METHOD OF PRODUCTION AND THE DIRECTION OF ROLLING ON THE PROPERTIES OF SHEET COPPER ROLLED TO VARIOUS THICKNESSES, W. Müller (*Zeits. Vereines Deutsch. Ing.*, 61. pp. 65-67, January 27, 1917.)

The tensile strength of sheet copper increases steadily with the reduction in rolling, the yield point increasing rapidly up to 20-30 per cent reduction; above this it is proportional to the ultimate strength. The elongation falls rapidly until the reduction in rolling attains 20-30 per cent, after which it remains nearly constant. With regard to the influence of the method of production, the modulus of elasticity is affected most in that the larger the grain size the higher the modulus. The hardness and the tensile strength, however, decrease with increase in grain size. No previous systematic investigation has been made of the influence of direction of rolling on mechanical properties, but it is generally assumed that the lowest strength is to be found at right angles to the direction of rolling. There appears to be a well-defined connection between the mechanical properties of the test piece and the angle which its axis makes with the direction of rolling; this is best shown by the bending test. Test pieces cut at 30 deg. to the direction of rolling exhibited the maximum resistance to bending. The modulus and tensile strength were found to be greater at right angles to the direction of rolling than in a direction parallel to it. Experiments on annealing showed that the increased strength of the sheets subjected to greatest reduction in rolling, is maintained after annealing at all temperatures. This hysteresis has been confirmed by a study of the specific gravities. (*Science Abstracts,* Section B, Electrical Engineering, vol. 20, part 9 [No. 237], September 29, 1917, p. 305)

Firing

NEW WAY TO BURN CRUDE OIL, W. A. Janssen

During the past year there has been developed a system of oil burning wherein the oil, instead of being atomized or vaporized, is gasefied in a special designed vaporizer outside of the furnace. The gaseous product is forced into a combustion chamber under positive pressure. The air for combustion is delivered by a compressor at about 2 lb. pressure and a velocity of 150 ft. per sec. With the admixture of oil in the vaporizer, a gaseous product is formed which is delivered to the combustion chamber under continuous pressure.

The cast-iron preheater, Fig. 7, consists of a closed cast-iron box with openings to connecting boxes for the admission of incoming air. A series of vertical flues are provided to permit a passage of the outgoing waste gases through the apparatus, thus providing a source of heat for preheating the air for combustion. When more than one preheater is used they are stacked one over the other, so arranged that the inlet

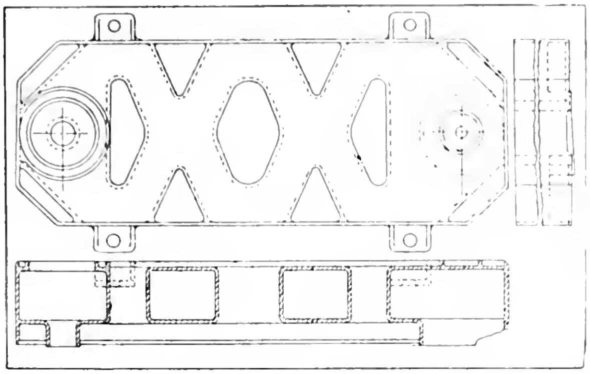

FIG. 7 GENERAL ARRANGEMENT OF THE CAST-IRON PREHEATER

opening of one connects with the outlet opening of another. The purpose of this arrangement is to throw out of line the vertical flues, thereby retarding the flow of outgoing gases and permitting a greater heat absorption through the walls of the preheaters.

The vaporizer, Fig. 8, is a hollow cast-iron fitting. Within it are a series of baffles, which form a winding, zigzag path for the gaseous mixture of the air and oil.

To obtain perfect combustion, the proportions of oil and air must be right and the temperature of the preheated air must also be correct. The installation operates most efficiently when the temperature of the air is about 800 deg. fahr., giving a net temperature of the gaseous mixture of about 700 deg. fahr.

The velocity of the gaseous mixture should be about 150 ft. per sec. in order to prevent flame propagation in the direction of the source. This is most essential, as the temperature of ignition, 1050 deg. fahr., is only a few hundred degrees higher than the temperature of the gaseous mixture.

To the heavy fuel oils of commerce about 180 ft. of free air are required per pound of oil, or about 1500 cu. ft. of free air per gallon—equivalent to 25 cu. ft. of free air per minute per gallon of oil per hour. High economies in oil consumption are claimed for this method. (Paper presented at the Annual Meeting of the American Foundrymen's Association at Boston, September 27, 1917, abstracted through *The Iron Age*, vol. 1, no. 18, November 1, 1917, pp. 1049-1050, 2 figs., *d*)

PROPORTIONING CHIMNEYS ON FUEL BASIS, Henry Wisostow

The writer believes that proportioning chimneys on the basis of formulæ given in handbooks and textbooks is not satisfactory, and suggests a somewhat different method, based on the following considerations:

The object which a chimney should accomplish is twofold: first, it should deliver sufficient fresh air to the fire to maintain combustion; and, second, it must discharge the products of combustion into the atmosphere. Hence, the best chimney is the smallest one that will do the work.

Contrary to the general idea, the composition of chimney gases runs very uniform for the same class of service and differs little with different services. The services may be divided into two classes, low-pressure for heating and high-pressure for heating and power or power alone.

The composition of chimney gases is largely affected by infiltration of air through the setting and into the gas passages. The average results from a large number of chimneys investigated are tabulated, as follows:

	Average CO_2, per cent	Average stack temperature, deg. fahr.	Average velocity, ft. per sec.
Low-pressure heating . .	4.5	180	10
High-pressure.	6.5	450	25

With the percentage of CO_2 given, the weight of the chimney gas can be figured closely. The quantity of the gas and the velocity are the two main factors determining the area of the chimney. Increase of velocity increases the stack loss, but this loss is not very large. Velocities of from 10 to 40 ft. per sec. are met in practice. With high velocities the rate of combustion is increased, which is followed by an increase in temperature, compensating for the increased draft loss due to a higher velocity.

Friction head in the chimney usually remains inside of 0.001 in. of water per lineal foot height of the chimney when the velocity remains under 30 ft.

Chimney height is determined by the amount of draft required. In cases where chimneys must be built higher than this, the area per pound of chimney gas can be reduced in inverse ratio to the square root of the height. The area is determined by the quantity of the gas per second and the velocity. As previously stated, a stack velocity of 25 ft. per sec. is a good working velocity, although for sharp, short peak loads a velocity of 30 ft. per sec. may be used. Chimney friction loss per foot under 30 ft. velocity per second will be inside of 0.001 in. of water. The gas weight may be obtained from the quantity of fuel required. The volume of gas is proportional to the temperature, and this may be taken as 450 deg. fahr. In all calculations absolute temperatures must be used. Draft required divided by the available draft per foot of height will give the stack height.

Available draft per foot of chimney for an average stack temperature of 450 deg. fahr. is equal to the actual difference in weight of the gases inside and outside of the chimney, expressed in inches of water per square inch, less 0.001 in. friction loss.

Composition of chimney gases can be taken as 6.5 per cent of CO_2, 11.5 per cent of O_2, and the rest nitrogen. From these figures the weight and volume can be obtained. Actual composition of the chimney gases varies slightly, there being a trace of CO, SO, SO_2, and slightly more nitrogen than was in the air. This is why the CO_2 and O_2 total 18 per cent in chimney gases instead of over 20 per cent, as in free air.

The quantity of combustible required to provide the desired amount of heat can be taken as composed of pure carbon with

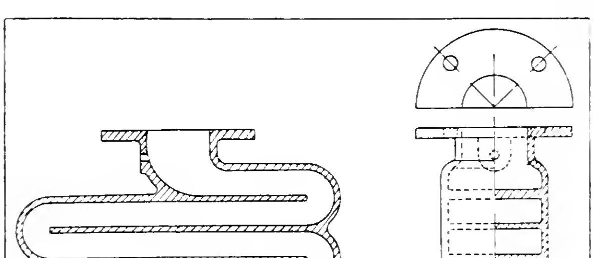

FIG. 8 CAST-IRON VAPORIZER

a heat value of 14,000 B.t.u. The combined efficiency of the boiler and furnace can be considered as 60 per cent for high- and 40 for low-pressure plants.

The foregoing data reduced for quick reference in practical work will be as follows: (1) Draft available per foot of chimney above the grate = 0.0063 in. of water, (2) combustible per horsepower, 4 lb., (3) area required per pound of combustible will be 14 sq. in. for high-pressure plants; (4) area correction for chimney above 150 ft. high per pound of combustible is (14 × 12/√H) (square root of chimney height). (*Power*, vol. 46, no. 18, October 30, 1917, pp. 610-611, *p.*)

Principles and Methods of a New System of Gas Firing, A. C. Ionides

The system described employs flues downwardly displaced in order to avoid any possible loss of heat.

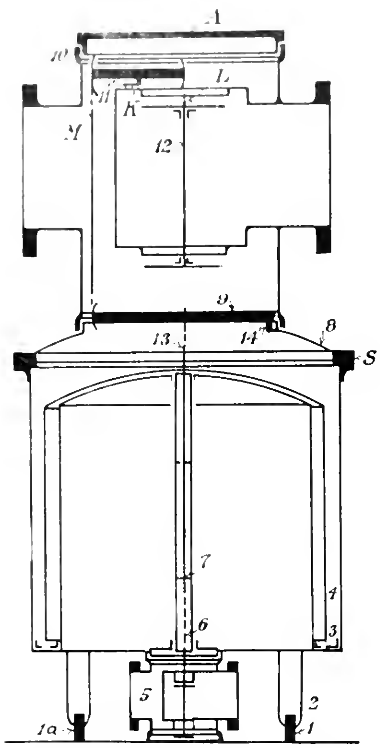

Fig. 9 Mixing Balance for the Ionides System of Gas Firing

The first problem that presented itself in applying this new principle was that of establishing and maintaining a constant mixture. There are three main variables to be dealt with as regards mixture: first, the inlet pressure of the air; second, the inlet pressure of the gas; third, the variation in consumption of either air or gas that may occur in any given installation.

The first problem was the most difficult to solve, since in many cases, as for domestic purposes, it was necessary to deal with considerable differences of pressure. This problem was solved by the construction of a device which the writer calls a mixing balance.

This balance, Fig. 9, consists of a sensitive bell, 4, with a requisite length of seal. The inside of this bell is subjected to the static pressure of gas and the outside to the static pressure of the air. Hence, when the static pressure of the gas increases, the arrangement is such that the flow of gas cuts itself off and the flow of air is, to some extent, increased. Likewise, when the static pressure of the air above increases, it shuts itself off and opens the gas correspondingly. As a result, the pressure of gas and air are always held in a constant ratio, whatever be the variation of either the inlet pressure of gas and air or consumption.

If the mixture of gas and air is rich in gas the flame is lengthened. On the other hand, if the proportions approach six or seven volumes of air to one of gas (according to the quality of the gas), it is quite possible, given silica or any other good catalyzer, to have no flame at all, but nearly surface combustion. Should a good catalyzer be placed at right angles to a stream of well-proportioned mixture, a glowing disk will be observed. On the other hand, if all catalyzers in front of this stream are avoided, the combustion can be spread

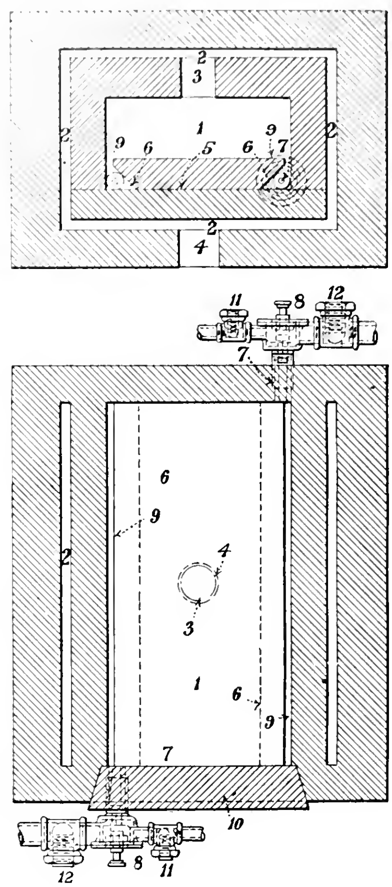

Fig. 10 Ionides Rectangular Barrel Furnace

out to a very considerable length. The author has proved by experience that with the ¾-in. injector, or even ½-in., it can be spread out to a length of 3 ft. of almost homogeneous combustion by putting the injector into the channel of firebrick open at the top. This permits even distribution of the heat units in a furnace or blower.

Next, it was found that the hotter the furnace grew, the less was the consumption of gas. This is, to a certain extent, due to expansion of gases by combustion. Assume that the gas mixture enters the furnace at, say, 15 deg. cent. If the temperature of the furnace was 1700 deg., it will have expanded to 1700/(273 + 15), or 5¾ times its initial volume.

If the waste gases, instead of passing into a chimney open at the top, are displaced downwardly through a contracted exit of predetermined cross-sectional area, this will cause a

resistance to the flow of incoming gases and provide the elements of the most refined thermostat without any mechanically working parts. It is claimed that by these means the temperature to be maintained can be predetermined by calculation.

The problem of determining the mixture was solved by a simple plan of fitting an ordinary gas cock with a piece of copper tubing bent with an easy bend and enlarged at the further end. Then a piece of india rubber tubing and an incandescent mantle are fed with the mixture, the light indicating the character of the mixture. If the meshes of the mantle are visible, it means an oxidizing mixture. If the mantle is in its most brilliant state, the mixture is very near the neutral point. On the other hand, if any unburned gas is seen to escape from the mantle in the shape of a blue flame, the mixture will be a reducing one. This provides a sensitive indicator.

The actual construction of the furnace is shown in Fig. 10. The operation of this furnace is as follows:

A heating chamber, 1, having a door, 10, at the front, is provided above and below, and, upon the greater portion of its sides, with two jacketing flue spaces, 2. The chamber, 1, communicates by one or two central apertures, 3, with the top flue space, and the heating elements passing through the said aperture pass downwards through the flues, 2, and are finally discharged through the outlet pipe, 4. In the bricks, 5, forming the floor there is provided along each of the two long sides a narrow combustion chamber, 6, into which the nozzle, 7, delivers mixture from a mixture device, 8, provided with gas- and air-adjusting means, 11 and 12. The long combustion chambers, 6, each deliver the products of combustion by a long, narrow slot, 9, into the furnace chamber, 1. The nozzle is positioned at one end of the long combustion chamber, so that the heating elements, due to their travel along the chamber and their upward motion to escape through the slot, 9, enter the furnace chamber, 1, with a diagonal movement parallel to the wall thereof. The gases passing along the wall will tend to turn at the angle when meeting the adjacent wall, and thus a whirling motion of the gases round the walls of the chamber will be created. If the nozzles of the two combustion chambers are arranged at opposite ends of the furnace, as shown, this whirling will be accentuated, the gases being gradually drawn inward across the roof of the furnace chamber on their way to escape at the outlet aperture, shown in the figure at 3.

A half-ton billet-heating furnace has been made, in which the gas consumption was 1.3 cu. ft. per lb. for full forging heat; the scaling was negligible. It is claimed that actual tests (data in original article) show that in brass melting an economy analogous to that afforded in steel forging can be effected. The Vickers Co. applied this system to a barrel-heating furnace, 36 in. by 12 in. by 3 in. inside, which resulted in their coming to an agreement to establish this system throughout their works.

As an indication of the correctness of the principles employed, the author would point out that a light worked by means of a pressure balance feeding a small incandescent mantle will produce 130 to 150 candlepower, with a consumption of under 3 cu. ft. per hour of town gas of standard calorific value; whereas, it can be stated on the authority of Mr. J. G. Clark in *Gas Journal,* May 4, 1915, that the highest-candlepower light obtainable at this pressure by other systems averages 22 candlepower per cu. ft. of gas consumed —variable, of course, owing to the atmospheric burner. (*The Engineer,* October 12, 1917, pp. 320-321, 5 figs., *d*)

Effect of Brick Arch on Smoke Abatement, J. T. Anthony

The paper refers mainly to locomotive practice, but some of its conclusions may have a bearing also in application to stationary boilers.

The Chicago Smoke Commission made extensive tests with and without the arch and found that the presence of the arch has certain beneficial results.

Tests recently conducted on a Mikado-type locomotive show smoke reductions varying from 50 per cent at low and medium rates of firing to 31 per cent at high rates of firing. The locomotive was hand-fired, using high-volatile Pennsylvania gas coal screened over a $1\frac{1}{4}$-in. mesh screen. This locomotive had 70 sq. ft. of grate area, a barrel combustion chamber and a 76-in. arch supported on four 3-in. arch tubes.

In these tests the increase in evaporation due to the arch varied from $8\frac{1}{2}$ to $15\frac{1}{2}$ per cent.

As regards the reasons why the arch decreases smoke, the following is to be borne in mind: With the conditions that prevail in the locomotive firebox it is easier to prevent the formation of soot than to burn it when once formed. The precipitation of soot can be prevented by having an excess of the heated air above the fuel bed. Research work done by the U. S. Bureau of Mines indicates that the hydrocarbons from the fuel bed are decomposed when they have traveled but a few inches from the top of the fuel bed, and hence if the precipitation of carbon is to be prevented the air or oxygen must be introduced at the top of the fuel bed and intimately mixed with the issuing hydrocarbons.

The chief function of the brick arch in abating smoke is that by baffling the gas mixture and compelling all the gases to pass through a relatively restricted area above the arch, an intimate mixture of the volatile combustible with the oxygen is insured. Where the arch is provided any excess air coming through this portion of the fire on the front of the grates is heated up, deflected and forced back over the end of the arch where it is mixed with the gaseous combustibles rising from the green coal under the door.

The results obtained with the arch depend, however, materially upon the method of firing. To reduce smoke to a minimum a slight level fire should be carried. With the fuel bed in this condition and a "scatter" type of firing being used, a uniform air supply is obtained throughout the fuel bed, as well as a uniform distillation of the hydrocarbons. (Paper read at the Convention of the Smoke Prevention Association, Columbus, Ohio, September, 1917; abstracted through *Power,* vol. 46, no. 16, October 16, 1917, pp. 540-541, *p*)

Handling and Conveying

Power Plant of the St. Joseph Lead Company,
E. L. Broome, Mem.Am.Soc.M.E.

Description of a new central plant serving several mining properties of the St. Joseph Lead Company, operating in St. Joseph, Mo. Of particular interest is the system of handling the coal and feedwater.

The coal is received from an elevated track discharging into a 30-ton steel track hopper underneath, by means of an opposed pair of reciprocating trough-shaped grizzlies. The smaller sizes fall into chutes at each side of the crusher and thence are fed directly to the belt. The larger pieces roll over the ends of the grizzlies and fall in the center into the crusher hopper, from which they are delivered on a 20-in. inclined belt conveyor driven from the upper end and provided with a magnetic pulley for the removal of pieces of iron. The belt

[illegible] a circular steel bunker 30 ft. in diameter, lined with 4 in. of reinforced concrete and having a capacity of 400 tons. Under the bunker is an 8-ton weighing hopper provided with an automatic registering scale beam and discharging into duplicate horizontal helical conveyors 12 in. in diameter, extending the full length of the boiler room over the stoker hoppers, the trough being provided with a rack-and-pinion operated sliding gate over each stoker. This solution of the fuel-supply problem results in a light, well-ventilated boiler room, while the spiral conveyors insure a very homogeneous condition of fuel at the stoker hopper and permit a uniform moistening of the fuel (this latter practice has been adopted to prevent coking and reduce dust).

Water for boiler feed is drawn for the mine and a maximum of softening is insisted upon. The mine water runs about 18 grains per gallon total hardness, equally divided between carbonates of calcium and magnesia. Two complete

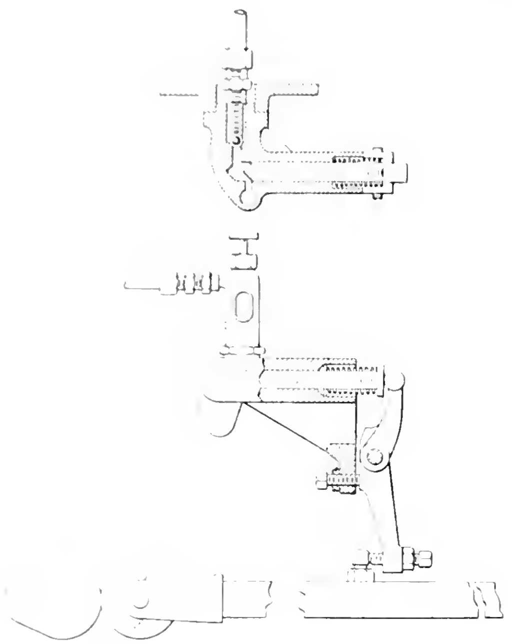

FIG. 11 SPECIAL OIL PUMP FOR LUBRICATING THE CYLINDER OF THE EVINRUDE OIL ENGINE

water-softening treatments have been installed. The lime-soda treatment of the continuous type takes the raw water at 18 grains per gallon hardness and reduces this hardness to five grains per gallon. This water is then passed through a pressure sand filter into a Permutit softening filter, where it is reduced to zero hardness. (*Power*, vol. 46, no. 18, October 30, 1917, pp. 582-585, 6 figs., *d*)

Internal-Combustion Engineering

ALCOHOL AND HYDROCARBONS AS FUELS

In 1916 a committee was appointed by the Minister of Commerce and Industries of France to consider the scope of national resources in fuels for internal-combustion engines. This committee has presented an extensive report from which the following data are abstracted.

In the first place, the report considers alcohol. It points out that in addition to grain alcohol proper enormous amounts of [illegible] alcohol can be derived from the treatment of [illegible]. The method of production of ethyl alcohol consists in the proper treatment of wood shavings or sawdust, from which may be obtained up to 15 per cent of alcohol (which is real ethyl alcohol, and not wood alcohol). In addition, alcohol may be prepared synthetically. In the first place, acetylene is produced from calcium chloride. Next, by an electric arc ethylene is extracted from acetylene, and this, in turn, gives sulfovinic acid, which is used for the production of alcohol.

Acetylene may be used in another way for the production of ethyl alcohol. The acetylene is passed through a solution containing one-thousandth part of bichloride of mercury, which results in the production of acetaldehyde, which latter, after being heated, is converted into alcohol by hydrogenation. The synthetic production of alcohol known in France only as a laboratory process is commercially used in Germany.

In view of the fact that a heavy tax exists on alcohol used for drinking purposes, all industrial alcohol must be denatured. In France a denaturing agent used is methylene containing 25 per cent of acetone and at least 2.5 per cent of pyrogenous impurities.

Among other things, it has been found that denatured 90 per cent alcohol can be used in gasoline engines under the following conditions: increased compression, altered distribution, and the employment of special means for preheating the charge and starting the engine. A more convenient method would have been the use of a mixture of three carbureting fuels in the present gasoline engines.

The use of such a mixture is based on the ability to satisfy certain conditions. In the first place, all these fuels should easily dissolve in each other in all proportions. Now commercial benzol containing 14 per cent of toluene and 1 per cent of xylene is very soluble in 90 per cent alcohol, but it would take 40 volumes of 95 per cent alcohol to dissolve 60 volumes of gasoline. Hence, for industrial purposes, it is necessary to use 95 per cent alcohol, of which 100 volumes dissolve 900 volumes of benzol and 150 volumes of gasoline.

It is very likely, however, that after the war benzol will be used in other industries, such as, for example, the production of dyes. In that case its price would make its use as a fuel prohibitive. In view of this possibility, the employment of ether-ethyl as an auxiliary fuel has been investigated.

The manufacture of ether is very simple, and its price is only seven or eight per cent that of alcohol. The only obstacle that lies in the way of its more extensive use is in the regulations of the French Excise Department. It appears that otherwise a mixture of alcohol, ether and kerosene could be used for both power and lighting purposes.

As regards the power purposes, extensive tests have shown that a mixture of 65 per cent of 95 to 96 per cent alcohol, with 10 per cent of ether and 25 per cent of a hydrocarbon fuel, can be burned perfectly well in an engine. In fact, with this mixture there is no trouble in starting an engine, and the consumption per volume is approximately the same as that of gasoline, at least for light vehicles.

The same fuel for stationary motors and trucks has given a less satisfactory result, the consumption per volume, as compared with gasoline, varying in approximately the inverse ratio of the heat values of the respective fuels. (*L'emploi de l'alcool industriel et des hydrocarbons comme carburants*, P.M., *Le Génèe Civil*, vol. 71, no. 14, October 6, 1917, pp. 225-228, 2 figs., *gp*)

EVINRUDE OIL ENGINE

In THE JOURNAL were given data on the Hvid cycle of oil engines. Essentially it is a high-compression cycle similar to that used in the Diesel engine, but with a different system of injecting the fuel. In the cylinder there is a cup with two

tiny openings at the side. The compression forces air through these openings so that the air in the cup is highly heated. This high temperature volatilizes a small portion of low-boiling fuel which is present in every oil and causes a sort of explosion in the cup, driving the fuel out in a spray.

The present engine is built by the Evinrude Motor Co. of Milwaukee, Wis. At present only $1\frac{1}{2}$-hp. and 3-hp. sizes are being built, but it is announced larger sizes will be added later.

The $1\frac{1}{2}$-hp. engine has a $3\frac{1}{4}$-in. bore and 5-in. stroke and is designed to operate at 600 r.p.m. The fuel tank is passed between the flywheels just over the crankcase, and fuel is supplied to the fuel cup by gravity.

The cylinder is lubricated by a special oil pump shown in Fig. 11. Oil from the lubricating-oil tank, which forms a small compartment of the fuel tank, flows to the oil pump through a side feed, and is then forced by the plunger through the cylinder wall to the surface of the piston. The pump is timed to operate when the piston is in its extreme outward position during the exhaust stroke. In this manner the oil is regularly and at the proper time fed in the cycle. (*The Gas Engine*, vol. 19, no. 11, November 1917, pp. 536-537, 6 figs., *d*)

Mechanics

THE DESIGN OF COIL SPRINGS, W. Ferrier Brown

In these notes it is the intention to simplify and accelerate the calculation of coiled springs as far as is practicable by embodying constants, which are supplied in tabular form.

The formulæ given in the various engineering pocketbooks for coil springs are practically alike, and differ mainly in the arrangement of the formulæ. The selection for these notes is that given in Lineham's Mechanical Engineering, as this has been proved to give accurate results.

The symbols used in this formula are:

D = diameter of wire in inches
Δ = total deflection in inches
W = total load in lb.
w = load per inch deflection in lb.
n = number of free coils
d = diameter of coil pitch circle in inches
c = 12,000,000 lb. for steel.

For round wire:

$$\Delta = \frac{8Wnd^3}{cD^4} \quad \text{.......... [1]}$$

$$\text{and } w = \frac{cD^4}{8nd^3} \quad \text{.......... [2]}$$

For square wire:

$$\Delta = \frac{60.5\,Wnd^3}{8cD^4} \quad \text{.......... [3]}$$

$$\text{and } w = \frac{8cD^4}{60.5\,nd^3} \quad \text{.......... [4]}$$

Equations [2] and [4] form the basis, and from these the total deflection can easily be calculated thus:

$$\Delta = \frac{W}{w} \quad \text{.......... [5]}$$

In addition to deflection, it is necessary to know the gage or diameter of wire of which to make the spring to take a certain load.

In Adams's Engineers' Handbook, the following formulæ are given:

Safe load (W) for springs, such as valve springs

$$= \frac{1,750\,D^3}{d} \quad \text{.......... [6]}$$

This can be transposed to read:

$$D = \sqrt[3]{\frac{11,750}{Wd}} \text{ for round section.. [7]}$$

For square section wire use the relation

$$D = \sqrt{\frac{Wd}{15,000}} \ldots\ldots [8]$$

[illegible] for springs that can be worked almost to the elastic limit

$$\frac{5,400\,D^4}{[illegible]} \ldots\ldots [9]$$

$$\text{or } D = \sqrt{\frac{Wd}{27,400}} \text{ for round wire.. } [10]$$

$$\text{and } D = \sqrt{\frac{Wd}{30,000}} \text{ for square wire. } [11]$$

On examination of Equations [2] and [4] it will be seen that the term cD^4 is a constant factor, and has the values $cD^4/8$ in Equation [2] and $8cD^4/60.5$ in Equation [4].

Let the constants be represented by k. Equations [2] and [4] will then read:

$$w = \frac{k}{nd^3} \ldots\ldots\ldots\ldots\ldots\ldots [12]$$

The value of k will be selected from the column for round or square wire, as the case may be, in Table 6.

In this table values of k for round and square wire have been calculated over a range of from 7/0 S.W.G. to 25 S.W.G. This range covers the average run of automobile work. Special cases can always be calculated from the equations in their original form, i.e., Equations [2] and [4].

Table 7 gives the cubes and the fourth powers of the various gages. These are used in conjunction with Equations [2], [4], [6] and [9].

Refrigeration

Corrosion of Brine Pipe, F. N. Speller

A report of a recent experience with corrosion of brine coils in an ice skating rink in Pittsburgh, Pa.

The pipe used was $1\frac{1}{4}$-in. double-length butt-welded standard-type steel pipe. It was found that after a comparatively short period of service the pipe was badly pitted.

The pipe was first used in the rink, but during the following summer was stored on a river barge. An analysis of the rust and scale from the inside of this pipe indicated in some cases a considerable amount of calcium chloride.

It appears that the pitting may have been due to two causes. First, heavy mill scale which is incidental to the practice of making butt-welded pipe; but while the cinder is present in all pipe and is an accelerator of corrosion on account of its electronegative character compared with iron, corrosion can only occur when moisture and oxygen are present together. Here is where the presence of calcium chloride in the scale comes in. Pure calcium chloride with pure water is not very corrosive, especially at low temperatures out of contact with the air, but when present even in small quantities on the inside of a moist pipe it will retain this moisture on account of its hygroscopic character. It appears therefore that the pipe was subjected to a combination of elements, such as mill scale, calcium chloride, moisture, oxygen and temperature above normal during the summer months, all of which tend to accelerate corrosion.

From data given in the article it appears that the fact that the pipe was steel had comparatively little to do with the result, which was due to improper conditions of storage of the pipe. (*A. S. R. E. Journal*, vol. 4, no. 2, September, 1917, pp. 220-224, 1 fig., *p*)

Railroad Engineering

Santa Fe Type Locomotives for the Union Pacific System

Description of locomotives now being built by The Baldwin Locomotive Company for the Union Pacific System. The locomotives are of a heavy and powerful design, so arranged that either coal or oil can be used.

An interesting feature is the trailing truck (Delta), built with a massive steel casting, which serves the triple purpose of a frame, radius bar and equalizer. The truck is equalized with the two rear pairs of drivers. The equalization is through a central, vertical heart-shaped link, which is suspended from a transverse beam hung from the rear driving springs. This link acts not only as the equalizer connection, but also as the rear-truck radius-bar pin. It is circular in section at its lower end, and is guided in the frame cradle casting. The bearing between the equalizer frame of the truck and the locomotive frame is made with a spherical surface to provide sufficient flexibility. (*Railway Review*, vol. 61, no. 18, Nov. 3, 1917, pp. 541-542, 2 figs., *d*)

Automatic Straight Air-Brake System

Description of a new air-brake system recently announced by the Automatic Straight Air-Brake Company for freight and passenger equipment.

This brake system provides a quick-action passenger brake, one brake cylinder being used for a service application and two brake cylinders for an emergency application of the brake. As the triple valve is capable for compensating for varying volumes in brake cylinders, a two-brake cylinder can be added to existing freight equipment for empty and load braking.

Due to its construction and operation this brake has the characteristics of a straight air brake, and, at the same time, is automatically operated. The straight air features are obtained through the fact that with every application of the brakes air is exhausted from the brake pipe under each car.

Design of the triple valve is such that, when fully charged, the pressure in the brake pipe, acting on the underside of the diaphragm, balances the pressure in the auxiliary reservoir acting on the upper side. The reduction in brake-pipe pressure causes the auxiliary-reservoir pressure to force the diaphragm downwards, admitting air to the brake cylinder from the brake pipe and service reservoir. The air in the brake cylinder acts on a second diaphragm which is connected to the first and which is of half its area. The pressure in the auxiliary reservoir remains unbalanced, forcing the diaphragm down until the force exerted by the brake-pipe pressure on the underside of this diaphragm, plus force exerted by the air in the brake cylinder on its diaphragm exceeds it. The diaphragm will then be raised and the supply of air to the brake cylinder cut off.

Hence, the brake-cylinder pressure bears a direct relation to the brake-pipe reduction and is not affected by the brake-piston travel or brake-cylinder leakage. By regulating the brake-pipe pressure any brake-cylinder pressure may be obtained. Besides, each triple valve is provided with means for making a graduated or quick release.

One of the features of this brake is that service applications can be varied at the will of the engineman by his regulation

of the brake-pipe pressure without the necessity of releasing the brakes before a reapplication when operating with the graduated release.

The article describes in detail the operation of the brake, and gives data of exhibition tests made by the company on a 100-car test rack. (*Railway Age Gazette*, vol. 63, no. 16, October 19, 1917, pp. 697-700, 4 figs., *d*)

Thermodynamics

Performance and Design of Surface Feedwater Heaters, M. C. Stuart, Mem.Am.Soc.M.E.

The writer develops his theory of heat transmission from the fundamental law that heat transmission is proportional to temperature difference.

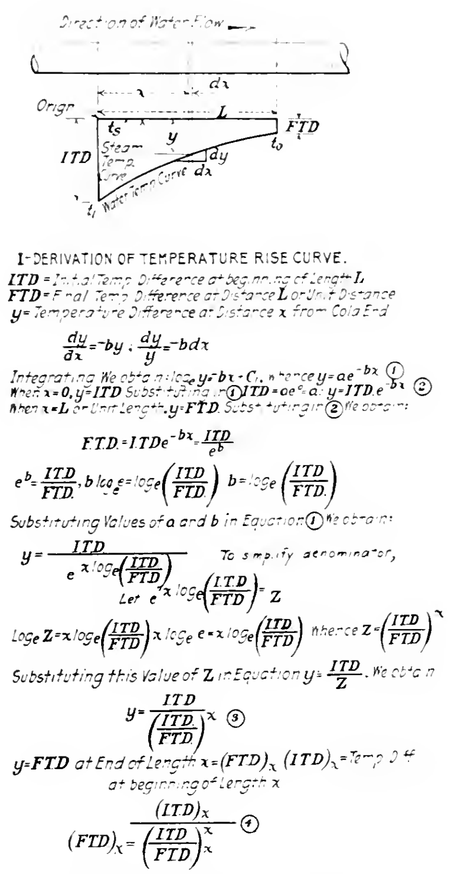

Fig. 12 Derivation of Curve of Temperature Rise

This assumption in the case of a tube with steam on one side and water on the other side of the metal wall may be expressed by the differential equation $dy/dx = -by$, which after integration, reduces to the equation of the temperature-rise curve (1), Fig. 12. After determination of the values of the constants a and b, in terms of temperature, this equation is reduced to the simple forms (3) and (4), Fig. 12.

From this the writer proceeds to the determination of, first, the mean temperature difference between water and steam, and then of heat-transfer rate from steam to water, Fig. 13, the mean temperature difference being defined as the average distance between the curves of steam temperature and water temperature.

Experimentally, the validity of the theoretical relations between temperatures and tube lengths may be best demonstrated on multi-pass feedwater heaters, in which temperature readings are obtained at the end of each pass because such tests give simultaneous data for performance of identical sections of a heater with identical conditions of steam pressure and water flow.

A recent test of a four-pass heater, made at the U. S. Naval Engineering Experiment Station, Annapolis, Md., gave the following data for a run in which the water velocity was 5.14 ft. per sec. and the steam temperature was 227.2 deg. fahr.

	Water Temperatures, Deg. Fahr. Inlet	Outlet
First pass	85.6	133.4
Second pass	133.4	165.8
Third pass	165.8	186.7
Fourth pass	186.7	201.3

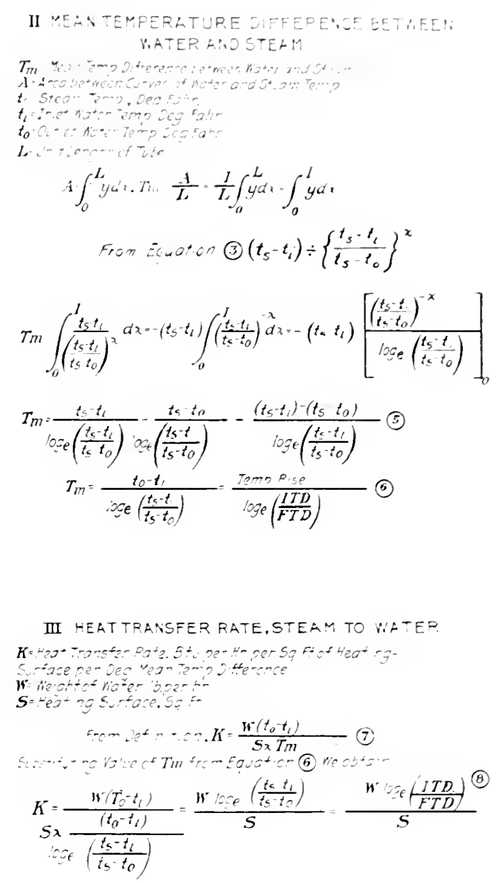

Fig. 13 Derivation of Curve of Mean Temperature Difference and Heat-Transfer Coefficient

These temperatures are plotted in Fig. 14 in what may be called a temperature diagram. The abscissæ are the inlet temperatures of the several passes and the ordinates are the corresponding outlet temperatures. A base line is drawn diagonally across the diagram through points of equal temperature, and the line of inlet temperature vs. outlet temperature, which is drawn through the plotted points, is extended to meet the base line at a point corresponding to the steam temperature, this line intersecting the base line at the steam temperature, because if water enters any pass at the temperature of the steam there will, of course, be no temperature rise and the temperatures of inlet water, outlet water, and steam will be equal.

In a multi-pass heater the outlet temperature of one pass becomes the inlet temperature of the next pass, as shown graphically by the "stairway" formed between the tempera-

... in one line, both indicated in the figure ... the relation between the temperature diagram and the theory, as previously developed, the following is ... If the temperature line of the diagram is straight and ... the base line at the steam temperature, it is evident that the ratio of initial temperature difference to final temperature difference is constant. From formula [8] for the ... heat transfer coefficients, it is seen that the constant value of W and S, as existing in the several passes of the ... pass heater K, will be constant if the ratio (I. T. D.) to (F. T. D.) is constant. Inasmuch as the temperature diagram satisfies this condition, this confirms the theory that the

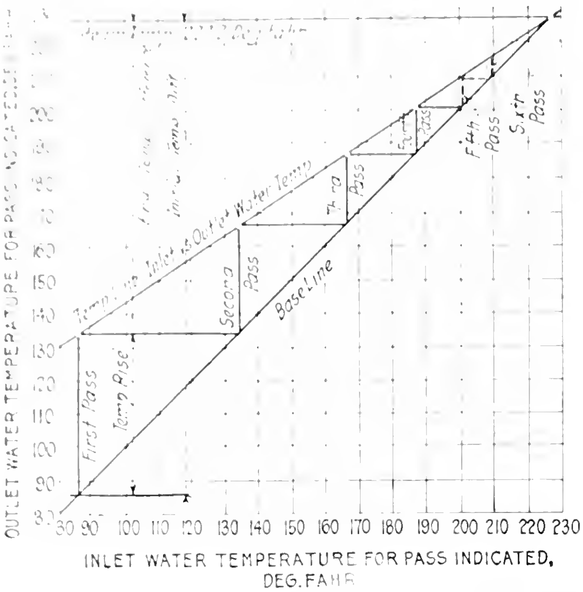

FIG. 14 TEMPERATURE DIAGRAM FOR FOUR-PASS FEEDWATER HEATER BY SEPARATE PASSES

heat-transfer coefficient is independent of temperature and depends only on the ratio of initial to final temperature difference.

To extend the method to another field, there is shown in Fig. 15 a temperature diagram plotted from the classic test of Mr. G. A. Orrok, Mem.Am.Soc.M.E., on The Transmission of Heat in Surface Condensation, published in the Transactions of the American Society of Mechanical Engineers, 1910, p. 1139. The test was made upon a single condenser tube through which water flowed, and which was surrounded by steam. The line DF was plotted from runs in which the steam temperatures were constant at 115 deg., and the inlet-water temperatures varied from 53 to 110 deg. fahr. The line BC was plotted from runs in which the water temperatures were constant at 50 deg. and the steam temperatures were varied from 115 to 187 deg. fahr. Space will not be taken here to analyze these results, but it may be stated that the temperature line BC is straight and the line DF is nearly straight, and that from the formula for heat-transfer factor $K = \frac{W}{S} \log_e \frac{\text{I. T. D.}}{\text{F. T. D.}}$ it is seen that a straight line on the temperature diagram corresponds to a constant value of K. The exact value of K along the temperature line may be determined from the ratio of $\frac{\text{I. T. D.}}{\text{F. T. D.}}$ as found from the temperature diagram, and the values of W and S. The effect of tube length on water temperature may be shown by forming a stairway between the temperature line and the base line.

The analytical relation between tube length and temperature rise along the tube was derived in Fig. 12 and is represented by formula [4]. In the present paper the writer gives three graphical methods of showing the relation between tube length and water temperature.

A logarithmic plot of heat-transfer factors and friction drop is given in the original article where the values of heat-transfer coefficients are plotted against water velocity on logarithmic coördinates. The relation between K and the velocity in feet per second may be expressed by the equation $K = 339\ V^{0.61}$, which form agrees with the results found by Orrok and others. The value of K may be composed from the value of the ratio $\frac{\text{I. T. D.}}{\text{F. T. D.}}$ as given by the temperature diagram and a temperature diagram for any velocity may be drawn by solving for the value of $\frac{\text{I. T. D.}}{\text{F. T. D.}}$ from the value of K for that velocity.

On the whole, the writer comes to the final conclusion that the design of a feedwater heater or other form of heat-transfer apparatus consists of determining the proper balance among the factors: tube length, number of tubes, velocity, total sur-

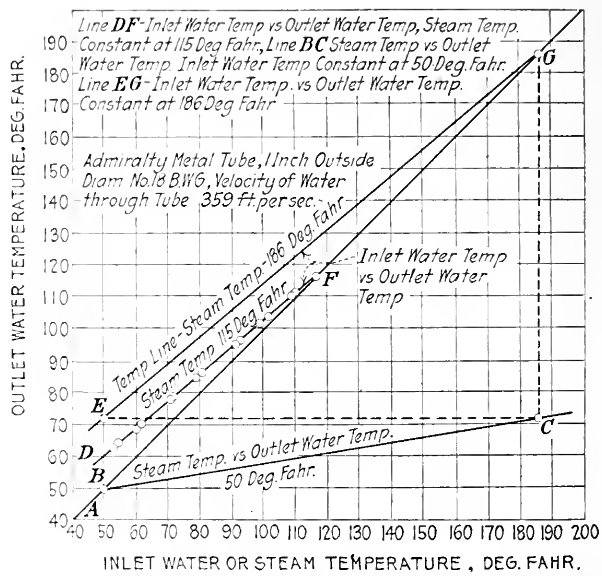

FIG. 15 TEMPERATURE DIAGRAM FROM TESTS OF CONDENSER TUBE BY GEO. A. ORROK

face, friction drop and temperature rise. An analytical method of design for feedwater heaters is likewise indicated. This method essentially is based upon the relation between heat-transfer coefficients and velocity. $K = aV^n \ldots$ [1], and the relation between friction loss and velocity $H = bLV^m \ldots$ [3]. By combining these two empirical equations with the theoretical equation for heat-transfer coëfficient, equation [2], there finally results equation

$$V^{1-n+m} = \frac{aC_2H}{bc_1 \log_e\left(\frac{t_s - t_1}{t_s - t_o}\right)}$$

(*Journal of the American Society of Naval Engineers*, vol. 29, no. 3, August 1917, pp. 503-524, 16 figs., *tA*)

Uses of the Sine Bar, E. J. Bryant. American Machinist, vol. 47, no. 18, November 1, 1917, pp. 749-751, 17 figs.

Technical Photography and Its Use in Industrial and Commercial Organizations, John H. Graff. The Journal of Industrial and Engineering Chemistry, vol. 9, no. 11, November 1, 1917, pp. 1052-1054.

CHARTS

Device for Calculating Time and Wages, Time and Wage Calculator, Foster B. Cooley. American Machinist, vol. 47, no. 19, November 8, 1917, pp. 819-820.

Chart for Determining Saturated Steam Discharge Through Orifices, Orifice Discharges for Saturated Steam, L. A. A. Karl. Power Plant Engineering, vol. 21, no. 21, November 1, 1917, p. 851.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

LIBRARY NOTES

From the Libraries of the Four Founder Societies and the United Engineering Society, in the Engineering Societies Building, New York City

U. E. S. Accessions

ABSORPTION OF METHANE AND OTHER GASES BY COAL. By S. H. Katz. U. S. Bureau of Mines. Technical Paper 147. *Washington, 1917.* Purchase.

AEROPLANE DESIGN. By F. S. Barnwell. A SIMPLE EXPLANATION OF INHERENT STABILITY. By W. H. Sayers. Robert M. McBride & Co., *New York, 1917.* Cloth, 5 x 7 in., 102 pp., 28 illus., $1.

THE J. E. ALDRED LECTURES ON ENGINEERING PRACTICE 1916-1917. The Johns Hopkins University, Department of Engineering, Baltimore. The Johns Hopkins Press, *Baltimore.* Paper, 6 x 9 in., 254 pp., 82 illus., 9 diagrams, 1 map. Gift of A. G. Christie.

APPLIED ELECTROCHEMISTRY AND WELDING; A Practical Treatise on Commercial Chemistry, the Electric Furnace, the Manufacture of Ozone and Nitrogen by High-Tension Discharges, and the Applications of Electric, Gas and Chemical Welding to Manufacturing and Repair Work. Part 1—Applied Electrochemistry, by Charles F. Burgess; Part 2—Welding, by George W. Cravens. American Technical Society. *Chicago, 1917.* Cloth, 6 x 8 in., 132 pp., 186 illus. $1.50.

BUILDING ESTIMATOR'S REFERENCE BOOK, THE. By Frank R. Walker. A Practical and Thoroughly Reliable Reference Book for Contractors and Estimators Engaged in Estimating the Cost of and Constructing all Classes of Modern Buildings. 2d ed., rev. *Chicago, 1917.* Leather, 5 x 7 in., 3535 pp., $5. Gift of the author.

CALIFORNIA RAILROAD COMMISSION. Decisions. Vol. XI, Sept. 1, 1916, to Nov. 30, 1916. *Sacramento, 1917.* Purchase.

CALCULATIONS USED IN CANE SUGAR FACTORIES; A Practical System of Chemical Control for the Sugar Houses of Louisiana, the Tropics, and Other Cane-Producing Countries. By Irving H. Morse. 2d ed., rewritten. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 4 x 7 in., 189 pp., $2.

CATSKILL AQUEDUCT AND EARLIER WATER SUPPLIES OF THE CITY OF NEW YORK, with elementary chapters on the source and uses of water and the building of aqueducts, and an outline for an allegorical pageant. *New York, 1917.* Gift of Mayor's Catskill Aqueduct Celebration Committee.

CATSKILL AQUEDUCT CELEBRATION, OCT. 12-14, 1917. Souvenir edition of Municipal Engineers' Journal. *New York, 1917.* Gift of Municipal Engineers.

CHEMICAL ENGINEERING CATALOG. 1917. Gift of Chemical Catalog Co.

CHEMISTRY IN THE SERVICE OF MAN. By Alexander Findlay. 2d ed. Longmans, Green & Co., *New York, 1917.* Cloth. 272 pp., 23 illus., 3 por. $2.

CLAYS OF THE PIEDMONT PROVINCE, VA. By H. Ries and R. E. Somers. Virginia Geological Survey. Bulletin no. XIII. *Charlottesville, 1917.* Purchase.

COKE-OVEN ACCIDENTS IN THE UNITED STATES DURING THE CALENDAR YEAR 1916. (U. S. Department of the Interior. Bureau of Mines. Technical Paper 173.) *Washington, 1917.* Purchase.

THE CONQUERORS. A special publication by the Cleveland Engineering Society. *Cleveland, 1917.* Gift of Society.

ELECTRICAL ENGINEERING: THE THEORY AND CHARACTERISTICS OF ELECTRICAL CIRCUITS AND MACHINERY. By Clarence V. Christie. 2d ed., McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth. 6 x 9 in., 546 pp., 508 illus., $4.

ELEMENTS OF MACHINE DESIGN. By O. A. Leutwiler. McGraw-Hill Co., Inc., *New York, 1917.* Cloth, 6 x 9 in., 607 pp., 339 illus., $4.

ENCYCLOPÉDIE, OU DICTIONNAIRE RAISONNÉ DES SCIENCES, DES ARTS ET DES MÉTIERS. vols. 1-36 and 3 vols. of plates. Ed. 3. By Diderot de d'Alembert. *Geneve, 1777-1779.* Purchase.

FLOATING DRYDOCKS. Edited by Sven Anderson. *Sparrows Point, Md.,* Maryland Steel Co., 1917. Gift of Author.

GEARS AND SIDE RODS OF ELECTRIC LOCOMOTIVES ON AMERICAN RAILROADS. By G. M Eaton. Westinghouse Electric & Manufacturing Co., *East Pittsburgh, 1917.* Purchase.

GYMPIE GOLDFIELD AND ENVIRONS, QUEENSLAND. Geological and Topographical Atlas. By B. Dunstan. (Queensland Geological Survey. Publication 221 A B.) 1910-1911. Purchase.

HANDBOOK FOR THE CATALOGER, U. S. GOVERNMENT PUBLICATIONS. By A. R. Hasse. Pts. 1-2. *Chicago, 1902, 1905.* Purchase.

HENDRICKS' COMMERCIAL REGISTER OF THE UNITED STATES, 1917-1918. S. E. Hendricks Co., Inc., *New York, 1917.* Cloth, 8 x 10 in., 2227 pp., $10.

INGENIERIA DE FERROCARRILES; La Teoria y Practica Fundamental de Ferrocarriles, Desde La Concepcion del Idea Hasta La Terminacion del Trazo. Por Verne Leroy Havens. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 4 x 7 in., 357 pp., 18 illus., 1 diagram. $3.50.

INTERNATIONAL ACETYLENE ASSOCIATION. Annual Convention. 17th, 18th (1 vol.). *Chicago, 1914, New York, 1916.* Gift of Association.

LEARNING TO FLY IN THE U. S. ARMY. A Manual of Aviation Practice. By E. N. Fales. McGraw-Hill Book Co., Inc., *New York, 1917.* Leather, 5 x 7 in., 180 pp., 39 illus., 1 pl. $1.50.

LIABILITY AND COMPENSATION INSURANCE; Industrial Accidents and their Prevention, Employers' Liability, Workmen's Compensation, Insurance of Employers' Liability and Workmen's Compensation. By Ralph H. Blanchard. D. Appleton & Company, *New York, 1917.* Cloth, 5 x 8 in., 394 pp., 13 illus. $2.

LUBRICATING ENGINEERS' HANDBOOK. A Reference Book of Data, Tables and General Information. By John Rome Battle. J. B. Lippincott Company, *Philadelphia* (copyright *1917*). Cloth, 6x9 in., 333 pp., 114 illus. $4.

MACHINE GUNS. Part 1—Mechanism, by Captain Julian S. Hatcher; Part 2—The Practical Handling of Machine Gun Fire, by First Lieutenant Glenn P. Wilhelm; Part 3—Machine Gun Tactics, by First Lieutenant Harry J. Malony. George Banta Publishing Company, *Menashaw, Wis.* (copyright *1917*). Cloth, 5 x 8 in., 233 pp., 84 illus., 3 diagrams. $2.50.

MECHANICAL DRAWING PROBLEMS. By Charles William Welck. McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth. 6x9 in., 153 pp., 120 illus., 1 pl. $1.25.

MEN WHO RECEIVED BUREAU OF MINES CERTIFICATES OF MINE RESCUE TRAINING JULY 1, 1914, TO JUNE 30, 1916. (U. S. Bureau of Mines. Technical Paper 167). *Washington, 1917.* Purchase.

MERCHANTS' ASSOCIATION OF NEW YORK. Year Book 1917. *New York, 1917.* Gift of Association.

MINERAL INDUSTRIES OF THE UNITED STATES. By Jos. E. Pogue. (U. S. National Museum, Bulletin 102, pt. 2.) *Washington, 1917.* Purchase.

MUNICIPAL ENGINEERS OF THE CITY OF NEW YORK. List of Members, By-Laws, Constitution, etc. 1917. *New York, 1917.* Gift of Municipal Engineers of the City of New York.

NATIONAL ASSOCIATION OF STATE UNIVERSITIES IN THE UNITED STATES OF AMERICA. Transactions and Proceedings. Vol. 15. 1917. *Grand Forks, 1917.* Gift of National Association.

OPERATION AND MAINTENANCE OF IRRIGATION SYSTEM. By S. T. Harding. McGraw-Hill Book Company, Inc., *New York, 1917.* Cloth, 6x9 in., 271 pp., 27 illus. $2.50.

PETROLEUM AND NATURAL GAS IN OKLAHOMA. (Oklahoma. Geological Survey. Bulletin no. 19.) *Norman, 1917.* Purchase.

PHILIPPINE LAND SHELLS OF THE GENUS AMPHIDROMUS. (U. S. National Museum, Bul. 100.) *Washington, 1917.* Purchase.

PRACTICAL APPRENTICESHIP. Bulletin no. 2—Fundamentals of Apprenticeship. n. p. 1917. Gift of Magnus W. Alexander.

PRACTICAL [illegible] By Terrell Croft. McGraw Hill Book Co., [illegible] 1917. Cloth, 6x8 in., 225 pp., 166 illus. [illegible]

[illegible] WELDS [illegible] Ed. 5 [illegible] Richardson [illegible]

[illegible] Endorsed by the [illegible] and the American Automobile [illegible] *Philadelphia* [illegible] Cloth, 5x7 in. [illegible]

[illegible] A Text and Reference Work for Engi[illegible] in Colleges and Technical Schools; [illegible] Self-Educated Men. By Ernest [illegible] Company, Inc., *New York, 1917.* Cloth, 6x9 in., [illegible] pp., 185 illus. $2.50.

[illegible] OF MINING ENGINEERS, METALLURGISTS AND CHEMISTS. By A. H. Fay. (U. S. Bureau of Mines. Technical Paper 179.) *Washington, 1917.* Purchase.

PRESERVATION OF STRUCTURAL TIMBER. Ed. 2. By H. F. Weiss. McGraw-Hill Book Co., *New York, 1916.* Purchase.

THE PRINCIPLES OF AEROGRAPHY. By Alexander McAdie. Rand, McNally & Co., *New York* and *Chicago* (copyright *1917*). Cloth, 6x8 in., 318 pp., 112 illus. $3.

PROPORTIONING CONCRETE MIXTURES AND MIXING AND PLACING CONCRETE. April 1916. Chicago, Portland Cement Association. Gift of Association.

PUBLIC UTILITIES REPORTS—ANNOTATED. D. 1917. *Rochester, 1917.* Purchase.

RECENT DEVELOPMENTS IN THE DESIGN OF MUNICIPAL WASTE DISPOSAL PLANTS. By G. R. Tuska. Reprinted from American Journal of Public Health. V, VII, no. 9. Gift of G. R. Tuska.

SCIENTIFIC OFFICE MANAGEMENT. By W. H. Leffingwell. A. W. Shaw Company, *New York* (copyright *1917*). Cloth, 9x11 in., 253 pp., 32 illus., 3 diagrams. $10.

SECOND PAN AMERICAN SCIENTIFIC CONGRESS. Proceedings. Vols. IV, V, VII. *Washington, 1917.* Gift of Pan American Union.

SELECTED BIBLIOGRAPHY ON PORTS AND HARBORS AND THEIR ADMINISTRATION, LAWS, FINANCE, EQUIPMENT AND ENGINEERING. *New York, 1916.* Gift of American Association of Port Authorities.

SOCIETY OF AUTOMOTIVE ENGINEERS, INC. Members, Officers and Committees. Aug. 1917. *New York, 1917.* Purchase.

SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS. Yearbook. 1917. *New York, 1917.* Gift of Society.

STEAM BOILERS. A Practical and Authoritative Discussion of Boiler Design and Construction, and the Development of Modern Types. Revised by Robert H. Kuss. American Technical Society, *Chicago, 1917.* Cloth, 6x8 in., 82 pp., 74 illus. $1.

STEAM CHARTS; and Special Tables for Turbine Calculations. By F. O. Ellenwood. John Wiley & Sons, Inc., *New York, 1917.* 49 pp., 18 charts. $1.

STOCKHOLM. KUNGL. TEKNISKA HOGSKOLAN. Program, 1917-18. *Stockholm, 1917.* Gift of Kungl. Teknisha Hogskolan.

SUBSTITUTION OF OTHER MATERIALS FOR WOOD. Studies of the Lumber Industry, Part XI. (U. S. Dept. of Agriculture. Report no. 117.) *Washington, 1917.* Gift of Department of Agriculture.

TABLES OF CUBIC CONTENTS OF LEVEE EMBANKMENTS. Designed by Arthur Alvord Stiles. (Texas Reclamation Department. Bulletin no. 5, June 1917.) *Austin, 1917.* Gift of author.

TASMANIA. Secretary for Mines. Report. 1915. *Tasmania, 1916.* Gift of Tasmania Mines Department.

TEXTBOOK OF NAVAL AERONAUTICS. By Henry Woodhouse. The Century Co., *New York, 1917.* Purchase.

THE THEORY AND PRACTICE OF SCIENTIFIC MANAGEMENT. By C. Bertrand Thompson. Houghton Mifflin Co., *New York.* Cloth, 5x8 in., [illegible] pp. $1.75.

[illegible] ENEMY. Act approved Oct. 6, 1917. Guaranty Trust Co., *New York, 1917.* Gift of Company.

A TREATISE ON THE ELEMENTS OF ELECTRICAL ENGINEERING. A Text [illegible] Colleges and Technical Schools. By William S. Franklin. Volume I, Direct and Alternating Current Machines and Systems. The Macmillan Company, *New York, 1917.* Cloth, 6x9 in., 165 pp., 368 illus. $4.50. Gift of the author.

U. S. FEDERAL TRADE COMMISSION. Report of the Commission on Anthracite and Bituminous Coal. June 20, 1917. *Washington, 1917.* Gift of Federal Trade Commission.

WATER SUPPLY ENGINEERING. The Designing and Constructing of Water Supply Systems. By A. Prescott Folwell. 3d ed., rewritten. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 6x9 in., 484 pp., 121 illus. $3.50.

WOOD AND OTHER ORGANIC STRUCTURAL MATERIALS. By Charles Henry Snow. McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth, 6x9 in., 478 pp., 90 illus. $5.

X RAYS. By G. W. C. Kaye. 2d ed. Longmans, Green & Co., *New York, 1917.* Cloth, 6x9 in., 285 pp., 115 illus. $3.

GIFT OF MELLON INSTITUTE OF INDUSTRIAL RESEARCH

BIBLIOGRAPHY OF SMOKE AND SMOKE PREVENTION. (Bul. no. 2) 1913.
DESCRIPTION OF THE NEW BUILDING OF THE MELLON INSTITUTE. By W. A. Hamor.
ESPECIAL VALUE OF RESEARCH IN PURE CHEMISTRY.
GROWTH OF THE INDUSTRIAL FELLOWSHIP SYSTEM.
OBJECT AND WORK OF THE MELLON INSTITUTE. By R. F. Bacon.
INDUSTRIAL FELLOWSHIPS OF THE MELLON INSTITUTE.
SERVICE TO INDUSTRY.
SOME PRESENT-DAY TECHNOCHEMICAL PROBLEMS. By R. F. Bacon.
SOME PRINCIPLES IN THE ADMINISTRATION OF INDUSTRIAL RESEARCH LABORATORIES. By R. F. Bacon.
SOME PROBLEMS OF CHEMICAL INDUSTRY. By R. F. Bacon.
WAR AND CHEMICAL INDUSTRY. By R. F. Bacon.
WILLIARD GIBBS PROFESSORSHIP OF RESEARCH IN PURE CHEMISTRY.

Above papers reprints from Science, Society of Chemical Industry, Jour. Society of Chemical Industry.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by December 17 in order to appear in the January issue.

CHANGES OF POSITION

SAKICHI ISHIMURA, formerly draftsman with Cornwall and Raymo, Inc., New York, has become affiliated with Nippon Deuchi and Company, of Kyoto, Japan, as engineer.

LLOYD LOGAN, formerly assistant mechanical engineer, Wescott and Mapes, Inc., New Haven, Conn., has become affiliated with the Union Sulphur Company, Sulphur Mine, La.

CHARLES J. SIMEON has accepted a position with the Curtiss Aeroplane Company, Buffalo, N. Y. He was formerly works manager of the Reed-Prentice Company, Worcester, Mass.

JOHN P. ILSLEY, formerly associated with the Niles-Bement-Pond Company, New York, has assumed the position of general manager of the Becker Milling Machine Company, Hyde Park, Mass.

HOWARD G. BENEDICT, works manager of the Aeromarine Plane and Motor Company, Keyport, N. J., has become affiliated with The Glenn L. Martin Company, Cleveland, Ohio, in a similar capacity.

WILLIAM S. LUCEY has become affiliated with the Hammermill Paper Company, Erie, Pa. He was until recently connected with the Eastman Kodak Company, Rochester, N. Y., in the capacity of mechanical engineer.

CHARLES F. MACGILL, formerly efficiency engineer with the Remington Arms and Ammunition Company, Bridgeport, Conn., has joined the engineering department of the Bullock Engineering Works, Inc., Bridgeport, Conn.

GEORGE F. NORDENHOLT, until recently chief inspector of the Harrisburg Pipe and Pipe Bending Company, Harrisburg, Pa., has assumed the duties of inspector of the Budd Manufacturing Company, Philadelphia, Pa.

H. P. AHRNKE, until recently western representative of the Dairy Machinery and Construction Company, Inc., Chicago, Ill., has become identified with the Davis-Watkins Dairymen's Manufacturing Company, Chicago, Ill.

E. L. C. CLARK, until recently connected with the New England Westinghouse Company, Springfield, Mass., has accepted the position of works manager of the Tractor Branch of the Moline Plow Company, Rock Island, Ill.

ANTHONY KENNEDY, formerly vice-president and general manager of the L. H. Miller Safe and Iron Works, Baltimore, Md., has assumed the duties of vice-president of The Hollar Company, bank vault engineers of Philadelphia, Pa.

ASA J. NEFF has terminated his relations with the American Public Service Company, Abilene, Tex., as efficiency engineer, to accept a similar position with the General Engineering and Management Corporation, of New York.

ROY S. KING has accepted the position of professor of experimental engineering at the Georgia School of Technology, Atlanta, Ga. He was formerly assistant professor of mechanical engineering at the University of Arizona, Tucson, Ariz.

LESTER G. CATTERMOLE, formerly in the employ of the Hannahs Manufacturing Company, Kenosha, Wis., has become connected with the Cooley and Martin Company, Chicago, Ill., in the capacity of efficiency engineer, specializing on woodworking.

CADWALLADER EVANS, JR., is no longer connected with The Delaware and Hudson Company, Scranton, Pa., as general superintendent of the coal department, but is connected with the International Salt Company, with headquarters at Retsoff, N. Y.

GEORGE S. BLANKENHORN has become associated with the American International Shipbuilding Corporation, Philadelphia, Pa., as assistant to the manager of machinery fabrication. He was formerly connected with the consulting engineering department of the Allis-Chalmers Manufacturing Company, West Allis, Wis.

FREDERICK W. LUCHT, JR., formerly on the engineering staff of The Denver Engineering Works Company, Denver, Colo., has become affiliated with the tool design department of the Packard Motor Car Company, of Detroit, Mich., in connection with Government work on the Liberty motor.

H. P. MEREDITH, formerly master mechanic of the Pennsylvania Railroad at Baltimore, Md., Sunbury, Pa., and Wilmington, Del., respectively, has become affiliated with the E. I. DuPont de Nemours and Company, of Wilmington, Del., as engineer in charge of mechanical maintenance, shop methods and efficiency.

HUBERT C. VERHEY has resigned his position as chief designing engineer for the marine Diesel engine department of the Busch-Sulzer Brothers Diesel Engine Company, of St. Louis, Mo., last April, in order to enter the consulting engineering field on Diesel engines, and has now entered the service of the Government in the capacity of chief draftsman of the Emergency Fleet Corporation, Washington, D. C., where he is slated eventually to take charge of Diesel-engine work.

ANNOUNCEMENTS

RUDOLPH H. FOX has accepted a commission of First Lieutenant in the Ordnance Officers' Reserve Corps.

HAROLD K. BEACH has joined the staff of the Cleveland Brass and Copper Company, as mechanical superintendent.

HERBERT H. KESSLER has received a commission as First Lieutenant, Ordnance Section of the Officers' Reserve Corps.

ERNEST R. KENNER has become associated with the Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa.

WILLIAM E. DOLL has been awarded a commission in the United States Army, 35th Engineers, reporting to Camp Grant, Rockford, Ill.

J. E. MACARTHUR, formerly superintendent at the Toronto, Ont., Canada plant of the Russell Motor Car Company, is now located at the Buffalo, N. Y., office of the same company.

GEORGE E. MERRYWEATHER, president of the Motch and Merryweather Machinery Company, Cleveland, O., has been named to take charge of the machine tool section of the War Industries Board.

WINTHROP G. HALL, superintendent of the Spencer Wire Company, Worcester, Mass., has been granted a 10-weeks leave of absence to enter Y. M. C. A. work at Camp Devens, Ayer, Mass.

HENRY C. ARMSTRONG, formerly metallurgical expert, United States Navy, has received a commission in the Ordnance Department of the Army as Captain in the Reserve Corps, and will be ordered to duty shortly.

W. C. BRIGGS, for the past ten years associated with W. A. Battey of the New York office of the Shepard Electric Crane and Hoist Company, in the capacity of sales engineer, has been made district manager of the company.

JOHN HUNTER, chief engineer for the Union Electric Light and Power Company, St. Louis, Mo., has been appointed by the U. S. Government to aid in directing the construction of the American marine fleet, with special charge of shipbuilding operations on the Passaic River in New Jersey.

R. K. HOLLAND, GEORGE E. ACKERMAN and H. K. HOLLAND, formerly associated with Gardner S. Williams, consulting engineer of Ann Arbor, Mich., have opened offices at Ann Arbor, Mich., and Chicago, Ill., under the firm name of Holland, Ackerman and Holland, consulting engineers.

WALTER C. ALLEN, president of the Yale and Towne Manufacturing Company, was granted leave of absence to enable him to respond to the call of the United States Government for service in France. Mr. Allen expects to be commissioned as a Major in the Signal Corps, and to leave soon for France, to take up the duties assigned to him.

F. W. HARDING, consulting engineer of the Canadian Consolidated Rubber Company of Montreal, Que., Canada, has in addition to his other duties taken direct charge of the Rubber Machinery Shops as manager. The Rubber Machinery Shops are owned by the Canadian Consolidated Rubber Company.

HARRY L. HORNING, vice-president and general manager of the Waukesha Motor Company, Waukesha, Wis., and chairman of the motor products section of the War Industries Board, was the guest of honor at the weekly luncheon of the City Club of Milwaukee, on November 3, and discussed the remarkable achievement of American automotive engineers in producing the new military truck in record-breaking time.

THE NEW BOOKS

ALL books received by The Journal will be listed under this heading, generally accompanied by brief descriptive notes. Works of special importance to mechanical engineers will be commented on at length by members and others peculiarly qualified by reason of their experience and training.

Unified Accounting Methods for Industrials. By Clinton E. Woods. [illegible] Cost Accounting, Etc. The [illegible] New York, [illegible] Cloth [illegible] in. 184 pp., [illegible]

The book opens with a review of the functions and duties of the new profession of industrial engineering, together with a clear statement of the general principles involved and the things to be accomplished.

The author states that the profession of industrial engineering has not as yet received the recognition required to clothe it with the dignity of a collegiate degree, as in other branches of engineering. This, I believe, is fortunate, for rather than extend the subdivisions of the only two logical divisions of engineering, namely, civil and military, the colleges would do well to abolish some of the divisions now recognized by collegiate degrees.

Attention is called to the great number of manufacturing concerns which are doing such a variety of work that they do not know where they stand. Their cost systems do not show on which articles they are really making or losing money —their only idea of distributing operating expense being by a lump sum prorated over the entire product.

The author advocates the departmental distribution of expense, and one would gather from his book that he would undoubtedly extend this to the more accurate method of distributing departmentally on the machine-hour basis.

The results obtained from standardization of equipment and labor methods are well covered, as are all the broader applications of industrial engineering.

The chapter on Analyzing an Industrial Manager's Monthly Balance Sheet will be of interest to all managers who are desirous of getting at the real facts regarding the businesses they manage. The forms shown illustrate the method used, and, of course, can be varied to suit any business. This fact should always be remembered in criticising forms. Forms are simply the tools used to collect information or to perform certain functions. No matter how excellent forms and blanks may be, they of themselves will not run a business.

The subject of General Stores is carefully described, and in this connection it is stated that "No departments in any manufacturing business contribute more to its health or wealth than do the departments of storekeeping." This is most true, for if a manufacturing concern has not absolute control of its stores it cannot do much along the line of industrial engineering. A visit through the factories of this country will show any experienced engineer how little this fact is recognized even at this late date, futile attempts at planning and at time and motion study being made by many people without even a thought to the matter of stores and the control of materials.

The author holds that the Stores Department should come under the Purchasing Department. This, I believe, is wrong from an organization point of view.

He also advises that "The price to be used for any costing or inventory purposes should always be that of the last purchase from any regular source of supply." This is entirely unnecessary if stores records are kept on a unit plan and each delivery of a particular material is kept separate, as is done by many up-to-date factories. Costing and inventorying can then be made on a basis of what was paid for material, not at the last cost.

While the methods of storekeeping described are well thought out, I believe that they are more complicated than there is need for, and they do not represent the latest thought on the subject. The chapters on Handling of Production Schedules are subject to this same criticism of complexity.

In Chapter X is noticed the expression "non-productive labor," which is the bugaboo of so many manufacturers. I think that all industrial engineers should refrain from using the expressions "productive" and "non-productive" labor, which are borrowed from the economist and have no place in modern manufacturing business. Much better is it if we substitute the more accurate terms "direct" and "indirect" labor. In a well-run concern there will be no non-productive labor, but there may be indirect labor. It should, I believe, be one of the duties of engineers to banish this misleading expression "non-productive labor."

Under Employment and Handling of Labor, the author advocates the paying of employees four times a month instead of once a week. The reason for this is that it saves the making out of one entire payroll per month, and the splitting of another, which is required by the weekly method. This method will undoubtedly save a little clerical expense but will probably not be acceptable to the employees. Workmen figure by the week, their rent, etc., being as a rule due at such periods, and they like to know definitely the day on which they are to be paid. To be paid on Monday one week and Tuesday the next, would, I believe, be an excellent method of starting labor difficulties. If the time cards are on a unit scheme and the payroll summed daily, the weekly pay and monthly total are easily secured with little clerical work.

It is unfortunate for business in general, and the manufacturer in particular, that our year is not made up of thirteen months of four weeks each, as this would have numerous advantages for purposes of comparison. Perhaps as the world advances we may yet come to this.

In Chapter XII the matter of organization is dealt with, as well as distribution of labor, material and expense. These are about the most important matters that the industrial engineer has to consider, and might easily take up a book in themselves. The methods illustrated are interesting and instructive.

The remainder of the book is devoted to accounting methods and principles, which are well handled.

While many of the details might not be agreed to by all industrial engineers, the work nevertheless presents a clear outline of the matter and forms a valuable addition to the literature of the subject. It would be well for many manufacturers who have been troubled during the past few years by the fact that they were not showing the profits they should, or were even encountering considerable losses due to antiquated methods of running their plants, to "read, mark and inwardly digest" Mr. Woods's latest publication.

George M. Forrest.
